During the last twenty-five years, knowledge of the temperature distribution in the stratosphere has accumulated. The meagre data from tropical regions have been supplemented by excellent series of observations in Batavia and in India, and in the far north the balloons sent up at Abisko in Lapland have yielded valuable information. It is now believed that over the tropics there is a considerable increase of temperature above the tropopause, the average temperature at 24 km. being about 220° A. On the other hand, near the Arctic Circle there is a wide annual range of temperature in the stratosphere. At 10 km. the range is from 212° A. in January to 227° A. in July. At 20 km. the averages in those months are estimated as 207° A. and 240° A.

The relations between pressure and temperature in the upper air were set out by W. H. Dines in 1911 in terms of correlation coefficients. Dines was impressed by the strong correlation between the pressure at a height of 9 kilometres and the other variables, the height of the tropopause, the temperature of the stratosphere and the average temperature of the troposphere. It looked as if the movements of the atmosphere must be dominated by developments taking place at the boundary between the stratosphere and the troposphere. The doctrine was neatly expressed by Gold in 1914 in "The Ballad of the Stratosphere".

"I am the rolling Stratosphere,
I long to perturbate;
So I tickle the top of the Troposphere,
To make him undulate."

Later investigations have concentrated attention on the lower strata of the atmosphere, and nowadays most of the meteorologists who are interested in the day-to-day changes of weather are content to regard the stratosphere as playing a passive rôle. There is, however, a school in Germany which regards 'stratospheric steering' as dominating the movements of cyclones and anticyclones.

The theory of the stratosphere has been developed by Simpson, who has demonstrated that the heat balance of the atmosphere is maintained in such a way that the energy of such solar radiation as is not intercepted and reflected by the clouds eventually escapes as long-wave radiation. According to Simpson, any increase in solar radiation would be followed by an increase in evaporation from the oceans and an increase in cloudiness. This would reduce the fraction of the solar radiation available for heating the ground, the oceans and the atmosphere, so that the rise of temperature would be comparatively small. It appears that the temperature of the stratosphere is governed by the properties of water vapour rather than by the strength of solar radiation. Simpson believes that the temperature would be changed but little if the earth received as much radiation as Venus or as little as Mars.

So early as 1875, Hann discussed the constitution of the atmosphere at great heights on the assumption that Dalton's law could be applied, each of the constituent gases behaving as if the others were not present. He showed, for example, that as oxygen is heavier than nitrogen the proportion of oxygen would fall off with increasing height. After the discovery of the stratosphere it was generally assumed that the same uniform temperature would prevail right through the atmosphere from the tropopause upwards, and that the density of each of the constituent gases could be calculated on that basis. Whilst the proportion of hydrogen in air near the ground was only three parts in 100,000, this gas was found according to the calculations to predominate at 80 km. and at greater heights. Wegener came to the conclusion that even hydrogen was not light enough to extend to the greatest heights at which aurora had been observed, and in 1911 he postulated a still lighter gas, geocoronium.

Faith in these calculations was rudely upset in 1922 when Lindemann and Dobson published their paper on "A Theory of Meteors and the Density and Temperatures of the Outer Atmosphere to which it Leads". Qualitatively there was little new in the theory of meteors. In his "Thermodynamik der Atmosphäre", published in 1911, Wegener says that on account of the great velocity of a meteor the air does not get out of its way but is compressed. The air is heated by compression, and heat from the air raises the superficial temperature of the meteor until it begins to evaporate. Wegener thought that the heated air would become visible, whilst Lindemann and Dobson insist that it is only when volatilisation begins that the meteor is seen. That is a small detail, however: the important step was to calculate how much air must have been encountered before the meteor would be raised to incandescence, how much before it was completely volatilised and therefore disappeared. The result of these calculations was that the air throughout the range of height through which meteors had been observed must be much denser, at 100 km. a hundred times denser, than the speculations

based on the hypothesis of uniform temperature had indicated.

The natural deduction was that the latter hypothesis was wrong The air at moderate heights must be sufficiently distended to support comparatively heavy air at the greater heights The case was met by postulating that the air at heights of 60 km and upwards was at a temperature of at least 300° A, about the average temperature prevailing on the ground It was pointed out afterwards that better agreement could be obtained by placing the base of this upper region of high temperature a good deal lower, at 40 km

THE TRANSMISSION OF SOUNDS TO GREAT DISTANCES

IT was a curious coincidence that Lindemann and Dobson discovered the high temperature of the upper atmosphere in 1922. The observational material which they used in their calculations had been available for at least half a century. On the other hand, when they announced their discovery, investigations were in progress which were leading to the same conclusion. That the sounds of explosions could sometimes be heard at very great distances though inaudible at smaller distances had been noticed long ago; there is a famous instance, recorded in the diaries of Pepys and Evelyn, of firing in the Straits of Dover being heard in London but not at Dover The first detailed investigation of the phenomenon was made by van den Borne after a dynamite explosion at Förde in Westphalia in 1904 Previously it had been supposed that abnormal audibility could be explained by the effect of wind, but van den Borne came to the conclusion that this explanation was not adequate, and put forward the hypothesis that the sound waves travelled through the atmosphere at a great height. In his calculations he utilised Hann's estimates of the amounts of different gases in the atmosphere According to these estimates hydrogen preponderated at heights exceeding 70 km. In an atmosphere of hydrogen the velocity of sound is about four times that in ordinary air. Van den Borne saw that waves passing from the lower atmosphere into an atmosphere which was mostly hydrogen would be refracted and would return to the ground. He reckoned that waves starting upwards in a direction inclined at 30° to the vertical would reach the ground about 116 km from the source after culminating at a height of 75 km.

The theory seemed to fit the observations, though there was a good deal of scepticism as to the possibility of waves being transmitted through such attenuated gas.

Wegener's account of the theory is followed by the remark that systematic investigations of these sound phenomena could probably be carried out at no great cost and were much to be desired. The Great War provided plenty of opportunities for qualitative observations and directed general attention to the subject, but as a test of theory observations of the time of transmission of sound were needed. After the War, experiments were inaugurated by the International Meteorological Organisation.

These experiments and others have demonstrated that van den Borne's theory cannot be valid, for the times taken by the sound of an explosion to reach various distances are much less than the times computed by that theory

When Lindemann and Dobson announced that the atmosphere at 60 km was probably at a high temperature, it was seen at once that this provided the explanation of the phenomenon of 'abnormal' audibility of sounds at great distances. The same explanation was in fact propounded by Wiechert shortly afterwards without any reference to the work of Lindemann and Dobson

The investigation of the waves from explosions has been carried on, mostly by the use of autographic records Records of the transmission of air waves to great distances were secured within the Arctic Circle in Lapland and in Novaya Zemlya during the Polar Year Observations which show that the outer zone of audibility is a universal phenomenon have been collected in other parts of the world

Accordingly it is probable that high temperatures occur in the upper atmosphere in all parts of the world and at about the same height. More definite information can only be obtained by multiplying observations under controlled conditions.

OZONE

The existence of ozone in the earth's atmosphere was revealed by a remarkable feature of the solar spectrum, the absence of ultra-violet rays of short wave-length The visible spectrum ends at about $0 \cdot 4\mu$, and photographs obtained with the quartz spectroscope show that there is a narrow band of ultra-violet, but this is cut off at $0 \cdot 29\mu$ In 1881 Hartley discovered that ultra-violet light was absorbed by ozone, and attributed to this gas the limitation of the solar spectrum, but Wegener, writing in 1911, passed over this evidence and based his statement that the quantity of ozone in the atmosphere increased with height on chemical analysis. He added, however, the remarks that the ozone was obviously produced by the action of ultra-violet solar radiation on oxygen, and the greatest part of this radiation was already absorbed at great heights. Accordingly, the distribution of ozone in a way which was inconsistent with Dalton's law was comprehensible.

The first estimate of the quantity of ozone needed to produce the absorption observed in the solar spectrum was made by Fabry and Buisson, whose work was first published in 1913 They announced that the ozone was localised in the atmosphere at heights above the regions accessible to man Their method was to compare the intensities of light in different parts of the Hartley band and at different elevations of the sun In this way they were able to eliminate the effects of absorption by haze and of Rayleigh scattering The quantity of ozone is very small; it is equivalent to a layer of the gas at normal pressure and temperature only 3 mm. thick If the ozone is in a layer 10 km deep at such a height that the average pressure is 1/20 of an atmosphere, then in that layer the number of oxygen atoms united in molecules of O_3 is only $1/(2 \times 10^4)$ of the number constituting O_2

The variations in the quantity of ozone in the upper atmosphere have been studied by Dobson with the aid of several collaborators The results are striking The annual variation in Europe has a range of about 30 per cent, the maximum occurring in the spring, the minimum in the late autumn. Both the mean amount (about 2 mm.) and the annual range are least near the equator Within the Arctic Circle the mean is about 3 mm. and the range is nearly 50 per cent of the mean There is symmetry in the northern and southern hemispheres.

No regular diurnal variation has been detected, but the amount of ozone varies with changes of pressure in the lower atmosphere There is more ozone above places where pressure is low, the maximum amount of ozone occurring a little to the west of the centre of a cyclone The minimum amount is observed a little to the west of the centre of an anticyclone These results are consistent with the hypothesis that the ozone is transported by currents from polar or equatorial regions, and indicate that the currents at the levels at which ozone is found are generally in the same direction as the currents nearer the ground.

The earlier estimates of the height of the ozone depended on measurements of the absorption of the ultra-violet light in the direct solar beam at different times of day and especially on measurements made when the sun was very low; but the investigators were never very confident about the estimates which they gave of about 50 km. for the centre of gravity of the ozone

Recently a new and powerful method of dealing with the problem has been developed by Götz, Meetham and Dobson This method depends on measurements of the intensity of the ultra-violet light from the sky in the zenith. The essential difference is that, whereas in the older method the height of the ozone is compared with the radius of the earth, in the newer the height is compared with the heights at which the density of the air has assigned values It is now found that the centre of gravity of the ozone is on the average at a height of about 21 km The published observations refer to Arosa in Switzerland and to Tromsø within the Arctic Circle in Norway, and the difference in height is insignificant In both locations the ratio of the densities of ozone and air is greatest at 35 km or 40 km. It should be noted, however, that the Tromsø observations were made only in summer

That the ozone is mostly below a height of 30 km has now been confirmed in a very direct way by Regener A spectroscope was carried up by a sounding balloon to about that height, and the spectrum of the light reflected upwards from a horizontal white surface was photographed automatically at regular intervals It was demonstrated that as the maximum height was approached the spectrum extended at the violet end, clear evidence that the balloon had passed beyond the greater part of the gas which absorbs the ultra-violet light

A "theory of upper-atmospheric ozone" has been developed by Chapman The theory is too difficult and elaborate to summarise here It may be mentioned, however, that oxygen is dissociated by the absorption of ultra-violet light of very short wave-length, that ozone is formed by the combination of molecular and atomic oxygen and that the ozone is eventually dissociated by the absorption of the ultra-violet of the Hartley band. Most of the oxygen atoms derived from the dissociation of ozone combine again to form new ozone molecules, so that the ozone is in a sense more persistent than the individual molecules of ozone One notable success of Chapman's theory is that he declared that the ratio of the densities of ozone and oxygen should pass through a maximum at a moderate height, so anticipating the results of observation

The theory that high temperature was produced in the upper atmosphere by the absorption of ultra-violet light was sketched by Lindemann and Dobson in 1922 in their paper on meteors The theory was elaborated by Gowan In his analysis he used the earlier estimates of the height of the ozone, and was led to the conclusion that, under certain assumptions as to the distribution of ozone and of water vapour, the air at such a height as 50 km. could be maintained at a temperature of 300° A., whilst much higher temperatures were to be expected at greater heights The results were not in accordance with those derived from observations of the transmission of air-waves, which put the base of the high-temperature region about 10 km. lower down. Gowan's work requires revision in the light of the recent determinations

of the height of the ozone layer, but at present it seems unlikely that the absorption of ultra-violet light by ozone and by oxygen can provide enough energy at the right levels to maintain the high temperature postulated to explain the refraction of sound waves It may be that the hypothesis of high temperature will have to be abandoned in favour of the view that the lightness of the atmosphere is due to the dissociation of oxygen It may also be that some source of energy has yet to be discovered.

AURORA

Whilst information as to the condition of the atmosphere at heights from 30 km. to 50 km. can be obtained in indirect ways, there is no method of investigating conditions between 50 km. and 80 km , though something can be gleaned from the occasional observations of meteor trails, which indicate that there are strong currents in this region 80 km. is approximately the lower limit of the aurora borealis in southern Norway Farther north there are few rays which come below 90 km. The majority terminate between 95 km. and 115 km., maximum frequencies occurring at 101 km. and 106 km. The upper ends of the rays are rarely above 400 km. during the greater part of the night, but after sunset, aurora can be seen above the earth's shadow extending to a height of 800 km. Krogness has suggested that the radiation pressure of sunlight drives the air forward so that the earth has a tail like a comet's, and that the high aurora is formed by corpuscles from the sun encountering this tail.

The spectrum of the aurora has been closely studied ; the majority of the lines in the spectrum are attributed to nitrogen, but the brightest, in the green, could not be identified with any line obtained in the laboratory until 1925, when McLennan and Shrum found it in an electric discharge through a mixture of helium and oxygen and demonstrated that the line was produced by a transformation of monatomic oxygen.

No lines associated with helium or hydrogen are observed in the auroral spectrum, so that it appears that the atmosphere in the highest levels consists of nitrogen and oxygen. It may be that any helium or hydrogen which diffuses to great heights is driven off in the comet-like tail of the earth.

It has been recognised for a long while that the corpuscles which produce the aurora carry electric charges and are diverted to the neighbourhood of the earth's magnetic poles by the action of the earth's magnetic field. The theory was elaborated by Birkeland about 1901 and has been developed further by Størmer. The height to which the auroral corpuscles penetrate is also the height of the lower of the two levels at which the atmosphere is a good conductor of electricity. These two layers have been discovered in the study of the transmission of wireless waves ; the lower is usually called the Kennelly-Heaviside layer and is at a height of about 100 km., the upper, discovered by Appleton, is at 220 km.

Chapman maintains that the ionisation at 100 km. outside the auroral zone is due to the bombardment of the atmosphere by neutral particles from the sun. These have about the same energy as the charged particles and penetrate to the same depth. The uncharged particles come straight from the sun, and therefore the supply is cut off at night. This theory is, however, open to question ; for the observations made on the occasion of the eclipse of the sun visible in North America in 1932 appear to indicate that the ionising radiation travels with a velocity nearly equal to the velocity of light.

The upper ionised layer at 220 km. is probably the region in which the ultra-violet light of very short wave-length is trapped by oxygen in the atomic state.

The two ionised layers are of importance in theories of terrestrial magnetism. Chapman believes that the upper layer is the seat of the electric currents which affect magnetographs at our observatories and produce the variations of magnetic force in the course of the solar day, and that electric currents in the lower layer are responsible for the variations which are governed by the moon, the latter currents being associated with tidal movements of the atmosphere.

A layer which has not yet been identified is that from which the light of the night sky comes It has been demonstrated that this light is not much-reflected sunlight and that it is not scattered starlight. The light must be generated in the earth's atmosphere by some slow process like the recombination of atomic oxygen. That atomic oxygen plays a part in the process is shown by the predominance of the green auroral line in the spectrum of the night sky. That the process is slow is proved by the fact demonstrated by Lord Rayleigh, that the intensity of the light varies but little during the night. Rayleigh finds in fact that the maximum intensity occurs about midnight. The layer from which the light comes must be rich in atomic oxygen. Chapman has given reasons for saying that this layer is probably between the Heaviside and Appleton layers.

Whilst the growth of knowledge of the upper atmosphere during the past twenty-five years has been rapid, there are probably more unsolved problems in sight than there were at the beginning of the period. It is safe to forecast that there will be a great consolidation of knowledge in the next twenty-five years, and that at the end of that period there will be still more problems awaiting solution.

Weather Forecasting

By DR G. C. SIMPSON, C.B., C.B.E., F.R.S., Director of the Meteorological Office

THE most important advance in weather forecasting during the last twenty-five years owed its origin to the War; but unlike so many other war-time advances, it was not made in connexion with the prosecution of war.

Twenty-five years ago, the method of weather forecasting, developed and described by Abercromby twenty-five years earlier, had undergone very little change. Synoptic charts were prepared and isobars drawn to indicate the pressure distribution. Seven main types of isobars were recognised, and Abercromby had described in great detail what kind of weather is usually associated with each. To take one example: the most common and most important pressure distribution is the cyclonic depression, and Abercromby prepared a diagram showing the weather association with this type of pressure distribution. He drew two ovals, one inside the other, to indicate the typical shape of the isobars; a long arrow was drawn along the major axis to indicate the line of movement of the depression, and the space within the oval was filled with descriptions of the weather which occur in the different parts. In the front of the depression *Pale Moon and Watery Sun* are indicated; in the right fore quadrant, *Muggy and Gloomy* are entered; and near the centre *Dirty Sky* and *Driving Rain* are noted. The forecaster having found a depression on his chart and determined the direction in which it was moving, would issue his forecasts on the assumption that places over which the depression would pass would experience the weather scheduled by Abercromby.

Abercromby's descriptions of the weather associated with each type of isobar were well done, and a very useful percentage of correct forecasts could be made; but the method was, by its very nature, unsatisfactory, for only average conditions could be forecast, and one knew from bitter experience that very large variations from type were possible.

Meteorologists were well aware that better forecasts could not be made on such a system, and that it was necessary to learn more about the physics of the atmosphere, and to take the upper atmosphere into account. For a number of years a very active investigation of the upper atmosphere had been carried on and important results had been obtained: the stratosphere had been discovered and many interesting statistical relationships between the conditions at different heights had been computed, but none of them appeared to be of much use in practical forecasting, and in any event no method was then known by which information regarding upper air conditions could be obtained sufficiently rapidly to be of use in preparing a forecast for the next twenty-four hours

Napier Shaw and Lempfert had tackled the problem in another way. They had investigated what happens in a depression by following the path of the air, and so determining where it came from and where it went The result was a classical paper on the "Life History of Surface Air Currents", and Shaw in a subsequent paper came very near to making the discovery which ten years later was to have such a revolutionary effect; but all this work, in spite of its great theoretical value, had produced very little to help the forecaster, and when the War broke out, Abercromby's empirical method was still the basis of all weather forecasting.

In Norway, although far removed from the seat of War, it was practically impossible to carry on the State Meteorological Service during 1914–18 owing to the total cessation of meteorological information from the outside world Under the guidance of Prof V. Bjerknes, the meteorologists decided to try to compensate for the loss of the foreign observations by increasing the observation posts within their own country. Prof. Bjerknes himself was a mathematician and not a forecaster, but there were two young men, one his own son J. Bjerknes, and the other H. Solberg, who took charge of the practical work The number of telegraphic reporting stations in the southern part of the country was increased from eight to about ninety. The observing stations were so close together that it was almost possible to follow individual masses of air from one to another.

When, by the aid of this close network of stations, the stream lines of the air were plotted, it was sometimes found that a broad and well-marked stream of air would seem to come to a sudden end. A long line could be drawn on the chart marking where the stream of air came to an end, and it was then found that beyond this line there was a strip of country, two or three hundred kilometres wide, over which rain was falling through a current of colder air flowing in a different direction. Further investigation, including a study of the temperature on each side of the line,

showed what was really happening In all such cases a stream of warm air had met a mass of cold air and been forced to ride over it, the cold air forming a wedge up which the warm air ascended When air is forced to ascend in the atmosphere in this way it is cooled and precipitation takes place, thus accounting for the rain beyond the line marking where the ascent began Frequently these broad bands of rain can be traced for thousands of kilometres across country.

On other occasions it was found that a broad stream of cold air would end as abruptly against a mass of warm air, but in this case the rain band would be much narrower than in the former case and would be situated before instead of beyond the line of junction. The explanation was simple In this case the moving air, being colder than the air against which it was impinging, could not ride over it, but must travel underneath In effect, a wedge of cold air pushed its way under a mass of warm air and lifted it upwards over itself The rain due to the ascending warm air fell through the wedge, and therefore appeared at the ground in front of the line of junction between the two air masses

It was war-time, so it was natural to liken the process to that of advancing armies and to call the lines of junction between the masses of the air which extended for so many miles across the country 'fronts' A front at which warm air advanced against cold air and was forced upwards was called a 'warm front', while one at which cold air pushed its way under warm air was called a 'cold front' There was nothing very revolutionary in the idea of one current of air overriding another without mixing, the two currents remaining separated at a surface where there was a discontinuity of temperature and air motion. Helmholtz had investigated the conditions in which such surfaces of discontinuity could exist, Margules had worked out the formula for calculating the equilibrium-inclination of such surfaces and Shaw and Lempfert had already recognised them on their synoptic charts. It was, however, the next step made by the Norwegians which was so important, for they showed that warm and cold fronts are an integral part of the formation and development of cyclonic depressions. A depression forms on a surface of discontinuity which, as the depression develops, becomes differentiated into a warm front and a cold front meeting at the centre; while the precipitation is chiefly associated with these fronts.

Thus at last a physical structure had been put into a depression, and Abercromby's distribution of weather had been brought into an ordered relationship with processes taking place in the upper atmosphere. From then on, the forecaster had a new tool called 'frontal analysis' with which to work He now searches his synoptic chart for fronts and surfaces of discontinuity, and when he finds them he knows what weather to expect When a front has once been located, the surface of discontinuity associated with it can be followed by characteristic cloud formation and rain bands for a very long time In this way the forecaster is able to foretell even minor changes of weather and to fix with considerable accuracy the time at which the changes will take place. This is of inestimable value in connexion with forecasting for aviation

Fronts and surfaces of discontinuity are due to the existence of different masses of air which are brought into contact, and it is now necessary to say a few words about 'air masses' Air which remains for any length of time in one locality takes up the temperature and humidity characteristic of that locality, thus the chief characteristic of the air in polar regions is low temperature, while that of air in tropical regions is high temperature When air from polar or tropical regions moves into mid-latitudes it does not immediately take up new characteristics, but it retains those of its place of origin for a relatively long time, and it is possible, especially when upper air observations are available, to determine the origin of the air over very large areas

The two main types of air masses are polar and tropical, but polar air may come from a sea area or from a continental area, and although in both cases the air will be cold it will have different characteristics of humidity and lapse rate. In this way 'maritime polar air' and 'continental polar air' have come to be recognised 'Mass analysis' is now an important branch of 'frontal analysis', and many different types of air masses are specified by different names. Each of these air masses has its own physical properties which are important from a weather point of view. Polar air is generally clear, with good visibility; maritime polar air is very unstable owing to the warming of its lower layers when passing over the relatively warm sea, and in it showers and squalls easily develop, tropical air is generally very stable, and showers do not occur in it, but it is the tendency of this air to override cold air which, aided by its high humidity, gives steady rain; the visibility is generally poor in tropical air. The forecaster has therefore come to examine more closely the air masses, first because of their intrinsic characteristics, and secondly because it is at the junction between air masses of different origin that surfaces of discontinuity occur.

It has already been mentioned that, at the

outbreak of War, upper air observations were not available, and if they had been forecasters would not have known what to do with them The conditions are very different now; for aeroplanes have made it possible to get the information quickly, and our new knowledge of the part played by air masses and surfaces of discontinuity makes all information from the upper air of great importance Practically all countries now use aeroplanes for upper air observations as part of their forecasting services.

There can be no doubt that during the last twenty-five years the forecaster has made great steps forward and forecasting is slowly being changed from an art, in which experience and intuition played the predominating part, into a science in which cause and effect are recognised and taken into account

Conceptions of Man's Ancestry

By SIR ARTHUR KEITH, F.R.S., lately Hunterian Professor of the Royal College of Surgeons

WHEN King George came to the throne, anthropologists had begun to realise that man's family tree was to prove a much more complicated thing than was anticipated The discoveries made in France between 1907 and 1909 compelled them to abandon the idea that mankind had been evolved by a single progressive series of stages which, beginning in an ape-like stage, ended in the races of modern humanity They had to give up the single-stemmed family tree and substitute for it one with rather a shrub-like outline Most of them regarded Neanderthal man as a stage in the evolution of modern man. The discoveries made in France, at the date just mentioned, proved that this could not be so, and that Neanderthal man, after occupying Europe for a large part of the pleistocene period, had been suddenly replaced by representatives of modern or neanthropic man Whether the neanthropic races, which replaced the Neanderthal inhabitants of Europe, came from Africa or from Asia still awaits determination Neanderthal man could not be fitted into any single-stemmed scheme, he represented the end twig of a dead branch. Since 1910, several more dead branches have been discovered and fitted into provisional reconstructions of man's family tree

At the beginning of this period another idea relating to the antiquity of modern man was being much discussed. Was it possible that human beings, exactly similar to modern Europeans in details of structure, could have been in existence in mid-pleistocene times, when the 100 ft terrace of the Thames was being laid down and the large Chelles hand-axes were being fashioned? There were many—including the writer—who answered this question in the affirmative The case we relied on was that of Galley Hill, near Gravesend, but discoveries of a similar kind had also been reported from France, from Italy and from North America. Galley Hill man lay under mid-pleistocene strata which were apparently unbroken. The discoveries which have been made during the past twenty-five years have not supported the Galley Hillites, the opposite has been the case Most anthropologists now hold that the human body is so unstable in its constitution—and always has been so unstable—that it cannot continue the same over a long period of time, but must change Hence we are all inclined now, in the case of Galley Hill and all discoveries of a similar kind, to reject the geological evidence rather than believe that the human body can exist for a long period of time—say, 50,000 years—and remain unchanged

Our knowledge of Neanderthal man has been greatly extended In 1911 Marcelin Boule published his classical monograph on the anatomy of La Chapelle man—perhaps the best known of Neanderthal specimens The earliest or oldest trace of the Neanderthal phylum is represented by the Heidelberg mandible, which was discovered in 1907 In spite of a prolonged search, this is still the sole trace we have of the ancestry of Neanderthal man in the earlier part of the pleistocene period Two discoveries, however, have revealed stages which fill up in some degree the interval between the early Heidelberg and late La Chapelle stages in the evolution of the Neanderthal type One of these was made in the travertine quarry at Ehringsdorf, near Weimar, in 1925; the other was made in a gravel pit, just outside Rome, in 1929 At Ehringsdorf and at Rome, the Neanderthal skulls were embedded in deposits formed during the long temperate interval which preceded the last glacial period The Ehringsdorf man was big-brained and had certain characters more reminiscent of modern (neanthropic) man than the later Neanderthal specimens. There are reasons for linking the discovery at Ehringsdorf with that made at Krapina, Croatia, in 1906 A discovery made in 1924 revealed the fossil remains of Neanderthal man in the Crimea, thus carrying the distribution of this extinct type almost into Asia

One very strange fact is that not a fossil bone of Neanderthal man has been found in England Traces of his body were found in Jersey by Dr R R Marett in 1911, and they have been found abundantly in France and in Belgium Yet the work-floors of Neanderthal man abound in the south-eastern parts of England Fossil remains of neanthropic man (*Homo sapiens*) have never been found in or under an intact stratum containing the stone implements of Neanderthal man—implements of the Mousterian culture This culture has always been found in association with Neanderthal man

The most remarkable and the most unexpected discovery of ancient man recorded in the period under review was made at Piltdown, Sussex, in the opening years of the King's reign Eager search over a long period had brought to light human remains in many parts of England, but always they were of the present-day type English anthropologists had come to believe that the first and only inhabitants of England were men of the modern type, when to the surprise of everyone the late Mr. Charles Dawson and Sir Arthur Smith Woodward produced Piltdown man—the most remarkable form of extinct humanity which has been discovered in any part of the world The criticism which this discovery has met with, ever since its first announcement, has in no wise detracted from its authenticity or its importance Piltdown revealed the fact that, at the beginning of the pleistocene period, England was the home of men who had in their structure a mixture of parts—most of them modern yet some strange, such as those of the forehead, and some ape-like, such as those of the lower jaw Indeed, the Piltdown lower jaw has been assigned by quite competent zoologists to an extinct kind of chimpanzee Sir Arthur Smith Woodward found small fragments of other individuals at Piltdown, but so far no other traces of this early type of man has been discovered in England or elsewhere in Europe It is usually held that Piltdown man (*Eoanthropus*) represents a form of humanity which died out early in the pleistocene period This, however, is a view which is not held so firmly now as it was formerly.

Another type of humanity in early England, authentic in all details relating to its discovery, came to light when foundations were dug for Lloyd's Buildings in the city of London in 1925. The London skull, which was found then, occurred under a stratum laid down in mid-pleistocene times. This places the ancient Londoner well within the period when the inhabitants of Europe were Neanderthalians Although the London skull is incomplete, yet there is enough of it to justify the exclusion of its owner from the Neanderthal category The London skull is essentially modern in character, but in the opinion of the writer it does show features which suggest a relationship to the Piltdown type Only further discovery can determine the significance of the London skull and its place in the evolutionary family tree

Although only a single specimen of the humanity which occupied England at the beginning of the pleistocene period has been discovered, yet there is abundant evidence that England was a home for evolving mankind as early as the pliocene period Just before 1910, Mr Reid Moir announced the existence of humanly worked implements in the sub-crag beds of East Anglia He has added to his evidence in every one of the twenty-five years which have elapsed since 1910, and now distinguishes at least three distinct stone cultures under the Red Crag of Suffolk

In 1925, students of fossil man had their attention directed to Palestine by a discovery made near Lake Galilee by Mr Turville Petre Deep in the floor of a cave, rich with stone implements of the Mousterian culture, he found part of a skull, which although Neanderthal in its main characters, yet had certain features which were of a different nature Between 1929 and 1933, Miss Dorothy Garrod, working for the British School of Archæology in Jerusalem, explored the caves of Mount Carmel, and found them laden with human relics of the pleistocene period In one cave Miss Garrod explored and examined a continuous series of superimposed strata 52 ft in thickness—the most extensive and richest cave deposit known to us The strata covered the period in which Europe was inhabited by Neanderthal man Altogether, remains of about fifteen individuals were found in the Carmel caves, six of which represent approximately complete skeletons The fossil remains of ten individuals lay in the smallest of the Carmel caves which was excavated by Mr Theodore McCown All the fossil remains from the Mousterian deposits of Mount Carmel are of the Neanderthal type, but like the Galilean specimen, show many strange features in some of which they approach the modern type of mankind. Thus we now know that for a very considerable part of the pleistocene period—roughly its middle third—Palestine was inhabited by a strange breed of Neanderthal man, some of them very tall and massively built As in Europe, the Neanderthal race was suddenly replaced by men of the modern type at the end of the Mousterian phase of culture The present belief is that these ancient Palestinians represent an extinct people.

Almost at the same time as Palestine, China claimed, the attention of students of prehistoric

man. By a series of isolated discoveries, it became known that the limestone hills at Chou-Kou-Tien, 37 miles from Peping, contained a vast cave packed with remains of the pleistocene period Most of the contents of the cave had been brought within the cave very early in the pleistocene period The oldest cave strata were found to contain crude stone implements, fossil remains of human beings and of hearths The fossil remains were found to represent a primitive form of humanity which Prof Davidson Black named *Sinanthropus*. *Sinanthropus* is certainly one of the oldest and lowest forms of humanity known to us His exact position in the family tree which represents the evolution of humanity is still uncertain Prof Davidson Black, who was cut off by death at forty-nine years of age in March 1934, was the man, above all others, who was best qualified to solve the enigmatic position of Peking man He died at Peping in the midst of his labours It may be that this ancient fossil type, so unlike any of the modern Mongolian peoples, may nevertheless prove to be on the line of Mongolian descent, for there are now grounds for believing that the chief races of mankind have been evolved in the continents they now inhabit

When the British Association met in Australia in the autumn of 1914, there was submitted to it a fossil human skull, known as the Talgai skull It had been derived from a pleistocene deposit in Queensland, and was marked by the cranial characters of the Australian aborigine, save that the jaws were more robust than is usual in the modern native and the brain was rather larger. The Talgai skull, which was described by Dr S A Smith in 1918, is the earliest representation of the Australian aborigine known to us

The publication of Dr S A Smith's monograph led Prof Eugène Dubois of Leyden to divulge a secret he had kept ever since 1891–92, when he was in Java and discovered the fossil remains of *Pithecanthropus erectus* He revealed the fact that he not only found these famous fossils, which came from very early pleistocene deposits—if not late pliocene—but also in deposits of late pleistocene date, two other fossil skulls These two specimens, known as the Wadjak skulls, like that of Talgai, had large jaws and also a great brain space Prof Dubois recognised that the Wadjak skulls had Australian affinities At first there was no suspicion of a direct relationship between the small-brained and lowly-placed *Pithecanthropus* and the large-brained Wadjak man. A discovery made by officers of the Geological Survey of Java makes it possible to believe that *Pithecanthropus* may be the ancestor of the Wadjak man, for the Solo skull, discovered in 1932, is intermediate to the other two skulls in many respects. It is intermediate in time and it is also intermediate in brain development We cannot assert as yet that the Australian aborigines have been evolved from a pithecanthropoid ancestor, but with the Solo, Wadjak and Talgai discoveries providing a series of rising evolutionary steps, we have now to consider seriously the possibility of such an origin for the Australian aborigine We have also to face the possibility of a separate or parallel evolution of various races of modern humanity Modern races may have come by their neanthropic characters independently of one another

In recent years, Africa has been providing evidence which raises a similar suspicion regarding the evolution of African races In 1913 there were discovered at Boskop, in the Transvaal, fossil remains of a big-brained specimen of humanity At first there was no evidence of its exact date, but now there are grounds for attributing it to a late phase of the pleistocene period The Boskop type, with a strikingly large brain and relatively small jaws, proved to be the forerunner of the Strandloopers of South Africa The Bushman type was also an inhabitant of South Africa in the later part of the pleistocene period as was proved in 1927 by the discovery of an ancestral form made by the Messrs Peers in the Fish Hoek Cave, in the Cape Peninsula The modern Bushman has not the size of brain or strength of jaw of his fossil ancestor The Boskop and Bushman are cousin types, and we may hope to find their common ancestor

Thus in later pleistocene times, Africa south of the Zambezi was the home of nearly related races, big in brain but short in stature At a much earlier period—perhaps as far back as the pliocene period, this part of Africa was the home of a remarkable anthropoid ape—one which made a nearer approach to man than either the chimpanzee or gorilla The existence of this remarkable ape—*Australopithecus* it was named by Prof Raymond Dart—was made known by the discovery in 1924 of a fossilised skull of a young individual in a limestone quarry at Taungs in the Harts River Valley some eighty miles from Kimberley The varying opinions formed by experts as to the significance of the Taungs discovery will be found in the columns of NATURE from 1925 onwards Indeed every discovery of ancient man made in recent years has found a full record in these pages

When we move to Africa north of the Zambezi, we enter another territory of human evolution Deep in the mine at Broken Hill, Northern Rhodesia, a remarkable fossil type of man came to light in 1921 The fossil type thus discovered is one of the most primitive forms of humanity known to us In his structural composition, Rhodesian man displays everything that we expect

in an early stage of the evolution of modern man (*Homo sapiens*). Unfortunately, there was nothing found with the bones of Rhodesian man which tells us at what point in the pleistocene period he lived; we infer from the circumstances in which he was found that he is at least mid-pleistocene in date Some light has been thrown on this and other problems relating to the history of early man in Africa by Dr Louis Leakey's researches Dr. Leakey led three expeditions to East Africa between 1925 and 1932, in the course of which he demonstrated the existence of implement-containing deposits covering the greater part of the pleistocene period Near the base of these deposits was discovered a fragment of a human lower jaw —which has characters not unlike those we expect to find in Rhodesian man In strata of later but of uncertain date at Kanjera, Dr. Leakey found cranial fragments of the most primitive type of Negro known to us At first sight, the difference between the Rhodesian and Kanjera types of humanity seems very great, and yet in the opinion of the writer it is possible to conceive the evolution of the Kanjera Negro from Rhodesian man Whether this evolution has taken place or not is one of the many problems which students of fossil man may hope to solve in the near future.

When King George came to the throne our knowledge of ancient man was almost entirely confined to Europe. Java was the only exception Discoveries of fossil man of extinct types have now been made in every continent of the world. Every large land area—Europe, Asia, Africa and Australasia—has yielded fossil remains of human types totally different from any now living—all save America No evidence has been found of the existence in the New World of a type of humanity that differs materially from types which still exist in America

Discovery and Significance of Vitamins

By SIR FREDERICK GOWLAND HOPKINS, P R S, Sir William Dunn Professor of Biochemistry, University of Cambridge

UNTIL the end of the first decade of the present century, official teaching concerning the nutritional needs of the human body was still based on the results of classical studies by Carl Voit and Max Rubner and on the views of the Munich School thence derived The adequacy of a dietary was measured in terms of calories and protein alone It was generally believed, alike by the academic physiologist and by those concerned with practical dietaries, that, questions of palatability and digestibility apart, so long as the food of an individual provided sufficient potential energy for the activities of his internal organs and for the external mechanical work he might be called upon to do, the only demand of a more specific kind made by his body was for a certain, rather ill-defined, minimum of protein, to subserve the growth and maintenance of its tissues. Beside the carbohydrates, fats and proteins which provide these essentials, natural foods were known, of course, to contain a variety of other substances. These, however, are present individually in very small amount, and except for certain minerals among them, necessary for the formation of bone and for the maintenance of particular physical conditions in the body, they assumed to be without nutritional importance.

Facts, nevertheless, were already known which might well have suggested that the body makes calls upon its food to supply needs more subtle and more specific than those thus recognised The history of scurvy, for example, and the clear demonstration, made already in the eighteenth century, of the dramatic cure of that fell disease which follows upon suitable, though relatively very small, additions to an errant dietary, should, it would seem, have provided a strong suggestion for the existence in certain foods of a substance small in amount but with highly specific properties essential for the support of normal nutrition, that is, for the existence of what we now define as a vitamin. But unfortunately, the views of the majority concerning the influence of anti-scorbutic foods remained for many years vague and obscure It was attributed to such qualities as 'freshness' without further analysis of these qualities, or to known constituents without proof of their efficacy True, so far back as 1841, an American physician, G. Budd, had ascribed the action of such foods "to an essential element which it is hardly too sanguine to state will be discovered by organic chemistry or the experiments of physiologists in a not far distant future". Had organic chemists or physiologists been then stimulated by this objective view to seek for a definite substance in such well-known anti-scorbutic materials as, say, lemon or orange juice—a substance which when isolated could display by itself the anti-scorbutic powers of these fruits—it is likely that a realisation of the significance of vitamins might have come

long ago, but current thought concerning nutrition was not yet prepared to profit from such suggestions.

Scurvy, of course, is now recognised as one of a group of so-called deficiency diseases—pathological conditions in each of which a group of symptoms is displayed, directly due to the lack of some necessary nutritional factor. It was in 1897 that evidence for the existence of another such disease was clearly revealed. Eijkman, a Dutch hygienist, had been led by extensive observations to the belief that the disease beriberi was associated with the consumption by human communities of polished rice as a basal food. He then found that it is possible to produce an illness in fowls similar to beriberi by feeding the birds on polished rice, and he was further able to prevent or cure it by administering an extract of rice polishings. The discovery that the disease could be thus produced and cured experimentally greatly assisted its study, just as the later observation of Holst and Frohlich that the guinea pig rapidly displays the symptoms of scurvy when placed upon scorbutic diets, while promptly cured by anti-scorbutics, made easy the experimental study of the latter disease and provided a ready biological test for the presence and relative amounts of the curative agent in various foods.

The explanation first offered by Eijkman for the production of beriberi during the consumption of polished rice was to the effect that the condition is a state of intoxication brought about by the consumption of excessive quantities of starch, and that in the so-called 'silver skin' which is removed by polishing, though not in the bulk of the grain, there is a substance which counteracts the toxic products of the disturbed metabolism. This hypothesis was far-fetched and inhibitory, but the conception of disease as the direct result of a specific deficiency in food was foreign to the thought of the time. Later, however, partly owing to the work of others and partly to extended experiments of his own, Eijkman came to the definite conclusion that there is present in rice polishings an individual substance differing from the then known food constituents, but essential to normal nutrition, though required in very small amount. Even before Eijkman himself had come to this final conclusion, the work of others had made it probable, and by 1910 the significant facts had become fully established. Among those whose work contributed to their establishment must be mentioned: Grijns, a countryman of Eijkman; Vedder and Chamberlain, of the American Medical Service; and the British investigators Fraser and Stanton, whose investigations were carried out in the Malay States. All of these helped to prove that the preventitive of beriberi is a definite chemical substance, and the last-mentioned in particular took pioneer steps which were ultimately to lead later workers to a successful isolation of that substance.

Those who worked on beriberi during these years thought and wrote as pathologists, with their attention primarily directed to the causation and cure of a particular disease. Though doubtless the suggestion for an extension of the kind of knowledge gained was ready to hand, as a matter of fact their writings at first contained no reference to the possibility that substances with the properties we now attribute to vitamins might function widely and prove to be necessary for the support of such fundamental physiological processes as growth itself.

This more general and more physiological conception of the functions of vitamins arose directly from the results of feeding animals on experimental diets. If the assumption were right that proteins, fats and carbohydrates, together with essential minerals, are the sole nutritional necessities, then these materials should support all the functions of the body when each of them is supplied in a pure form, no less adequately than when, in natural foods, they are consumed in association with small amounts of many other substances. The nutritional value of such purified materials supplied in artificial dietaries was at one time the subject of many experiments. The results of these were uncertain and contradictory, owing to the fact that purification was often not complete. It was not then realised that substances present in extremely small amount may profoundly affect the value of a diet. It is this circumstance that our present knowledge of vitamins has made so clear.

In 1906–7 the writer engaged in feeding rats upon highly purified materials of the above kind, and found them wholly unable to support health or normal growth, though certain additions, very minute in amount, greatly increased their nutritional adequacy. It happened that yeast extracts were among the addenda which were successful in this respect, but only, as is clear to-day, because the fat employed in these experiments was filtered butter fat. We know now that butter itself contains certain of the essential vitamins, while yeast supplied the others. These experiments confirmed a personal belief in the importance for nutrition of minor constituents in natural foods, and public expression was given to this belief, but the experimental results were not then published.

In the autumn of 1911 the results of later experiments were communicated to the Biochemical Society, and these were published in the following year in a paper which made a general claim for

the "importance of accessory factors in normal dietaries" Funk at about the same time impressively summarised the then available knowledge concerning deficiency diseases, and proposed the name 'vitamine' for the substance of which a lack might in each case be presumed to produce the pathological condition On chemical grounds J C Drummond suggested that the final 'e' in Funk's proposed name should be omitted, and this has become customary By 1912, then, there was fully adequate evidence for the wide importance of vitamins, and from that time progress in their study has been continuous

Immediately before the War and until near its end, American investigators were the chief contributors to this progress T B Osborne and L B Mendel at Yale and E V McCollum at Wisconsin (afterwards at Johns Hopkins University) were separately engaged upon nutritional experiments with artificial dietaries For a little while after the present writer's publication in 1912, these workers were not fully convinced of the necessity for a vitamin supply Osborne and Mendel believed for some time that they had succeeded in maintaining rats upon purified diets Soon afterwards conviction came, and important contributions to the subject were made at both centres In particular, American studies produced at this time proof that vitamins existed in natural foods in different associations, and led to a distinction between 'fat soluble' and 'water soluble' individuals, a distinction which, though in itself not of fundamental importance, greatly helped later developments in the subject, many of which have been due to workers in America

During the later stages of the War, when many nutritional problems had to be faced, intensive studies began at the Lister Institute in London These comprised pioneer work by A Harden and S. S Zilva, and the important experiments of Harriette Chick and her colleagues, which have continued to the present day At this time, University College, London, became also a centre of activity owing to the work and influence of J. C Drummond, while the classical experiments of E. Mellanby on the production of rickets were already in progress A few years later, interest in the subject penetrated into every European country, and research became everywhere very active Recently, publications dealing with vitamins have reached a total of a thousand in a single year

To-day we have knowledge of some eight or nine vitamins, each proved to have its own specific influence in maintaining the normal course of events in the living body, and each exercising its functions when in exceedingly small concentrations Happily the actual chemical constitution of some of them is now known

It is, of course, impossible in a brief review to recount all the stages of discovery in the case of each of these substances The existence of individual vitamins, each with its special influence in the body, has in the majority of cases been revealed by the experimental feeding of animals on the following general lines Natural products or preparations—crude when experiments began—from natural sources, animal or vegetable, when simultaneously added in characteristically small amounts to a vitamin-free dietary, were found to render it capable of supporting normal nutrition The tendency at first was to assume that each effective addendum contained one active ingredient The next step in progress, however, involved the fractionation of each crude preparation, and this in many cases revealed the presence of more than one vitamin, with obviously distinct functions, each calling therefore for separate endeavours towards its isolation and purification It may be mentioned in illustration that yeast, which because it represents a concentrated mass of living cells capable of active growth, and at the same time is available in large amounts, was early and justifiably looked to as a probable source of vitamins, has yielded some of them in a complex which even to-day has perhaps not been fully analysed

The position of knowledge at the present moment will be made sufficiently clear if the most salient characteristics of each recognised vitamin are very briefly reviewed Unfortunately, it is impossible at the same time to give credit to the many who have shared in the heavy labours involved in the remarkable recent advances in the subject

Vitamin A This vitamin is found in association with animal fats and exists in specially high concentration in the livers of fishes It was discovered and studied in cod liver oil, and at first was not distinguished from vitamin D, but by 1922 it had become clear that there were two 'fat soluble' vitamins with functions entirely distinct.

Vitamin A exerts an important influence in the body. In its absence young animals fail to grow Lack of a proper supply leads to degenerative changes in the epithelial cells which line the outer surfaces of the body, and among the characteristic symptoms which follow upon such a lack is a pathological condition of the eyes known as xerophthalmia. As an independent phenomenon night blindness may occur. Very noteworthy is the evidence which shows that an adequate supply of this vitamin protects against certain types of infection. One of the most interesting advances

in our knowledge of vitamins is the recent proof that vitamin A is closely related chemically to the carotenes, a group of yellow pigments widely distributed in plant tissues, and the further proof that carotenes, when they are consumed in green vegetables, are converted in the liver into the vitamin itself. These discoveries have thus shown that vegetable foods are an effective source of the vitamin, and they have also greatly helped in leading to our present knowledge of its actual chemical nature It has been obtained pure in the form of an oil, and chemical studies have revealed its essential molecular structure

Vitamin B_1 This is the vitamin of which a deficiency in the food supply leads as a final issue to the disease beriberi It exerts a general influence in the body, and would seem to be essential to the normal progress of carbohydrate metabolism, but a specialised aspect of its functions is the maintenance of a normal equilibrium in the nervous tissues It is widely distributed in natural foods, but in concentrations which vary greatly We have seen that the circumstance of its presence in the cortical parts of grains and absence from the endosperm led, through the work of Eijkman and his followers, to one of the earliest suggestions for the existence of vitamins It is relatively abundant in yeast, and this has been the material chiefly used as a source of it for experimental work. Much effort in Great Britain, in particular by R Peters, has been spent in the effort to obtain it in a pure state, an end which seems now to have been reached Its actual molecular structure is not yet known, but its empirical formula is probably $C_{12}H_{16}N_4OS$ Alone among the known vitamins it contains sulphur in its molecule

Vitamin B_2 When yeast extracts were first employed as addenda to deficient diets, their most notable effect, apart from the promotion of growth, seemed to be the prevention of nervous lesions. They were supposed to supply an 'anti-neuritic' vitamin alone This is now B_1 Further studies of such extracts showed, however, that they certainly contain at least one other vitamin more stable towards heat than B_1, and clearly showing quite different properties. In its absence serious skin lesions develop resembling in animals those seen in the human disease pellagra. There is now indeed little doubt that a prominent factor in the causation of this disease is a lack of this vitamin in the food. It has been labelled B_2. Quite recently, however, a further complication has come to light in this connexion. Preparations of 'B_2' as hitherto employed would seem to contain two active factors, one promoting growth without being concerned with skin conditions, and a second to which the 'anti-pellagra' influence is due The latter is now under intensive study, but its chemical nature is yet unknown The former, like vitamin A, is related, as shown by the researches of R Kuhn and P Karrer, to a group of naturally occurring pigments, but in this case to the flavines The vitamin is in fact identical with a flavine which is present in milk

Vitamin C While the prevention and curative influence of foods containing this, the anti-scorbutic vitamin, has been so long known, it remained for quite recent research to establish its existence as a definite chemical substance, to produce it pure and to determine its exact chemical nature It is present in most fresh foods but often only in very small amounts It is present in greatest concentration in fruits and green vegetables, but in amounts varying greatly from species to species Cereal foods contain none It is characteristically less stable than the other known vitamins, being destroyed when foods are long kept, dried or heated, the influence of oxygen being a potent factor in its destruction This instability accounts for many chapters in the long history of scurvy and its incidence Much labour has been spent during recent years in determining quantitatively its distribution in foods and in endeavour to isolate it Success in the latter aim was reached by A Szent-Gyorgyi three years ago Its constitution has been fully worked out by W N Haworth and his colleagues, revealing the interesting fact that the physiologically potent substance is related to the simple carbohydrates, being a derivative of the hexose sugar gulose The vitamin is now to be known as ascorbic acid.

Vitamin D This, the anti-rachitic vitamin, is generally associated with vitamin A in animal fats, and with the latter, is present in exceptionally large amount in fish liver oils Studies in the etiology of rickets have proved that this disease can be prevented or cured, on one hand by an adequate supply of this vitamin in the food, and, on the other, by adequate exposure of the body to sunlight A satisfactory explanation of this remarkable relation arrived with the proof that ultra-violet irradiation converts an inactive precursor into the vitamin itself, and that the former is present in the tissues. During the year 1929, owing in particular to the work of Rosenheim and Webster, and that of Hess and Windaus, it was made clear that the substance which on irradiation is activated is ergosterol, which in small amounts is present in most living tissues. As it is therefore present in many natural foods, the anti-rachitic value of these is increased by exposure to rays of suitable wave-length A preparation of the vitamin made by the irradiation of ergosterol *in vitro* is known as 'calciferol'. Its potency is remarkable; one ten thousandth of a milligram a day added to

a rickets-producing diet will in a rat entirely prevent the appearance of the disorder. In the case of a child the effective daily dose is a very small fraction of a grain. The rigorous proof that lack of a fat-soluble vitamin is responsible for the induction of rickets was furnished by the classical experiments of E. Mellanby begun twenty years ago More recently, the importance of vitamin D in the processes of normal dentition has been shown by May Mellanby.

Vitamin E In 1922 it was first shown by H M Evans and K S Bishop that a vitamin, distinct from others then known, is essential for successful reproduction. It has been termed the anti-sterility vitamin, but this term implies functions more specific than those which are actual Deprivation of vitamin A, for example, will ultimately lead to failure in reproduction. Nevertheless, the influence of vitamin E (now so-called) is exerted on specific lines In its absence, there is degeneration of the testes in the male and a failure of the placental functions in the female The richest sources of this vitamin so far discovered are certain green vegetables and wheat embryos It is, however, widely distributed in food-stuffs, and as it is active in very small amounts, the possibility of any lack of it can seldom arise Its constitution is unknown

These very brief descriptions of the known vitamins leave out, of course, a multiplicity of facts which have been discovered concerning each of them, and omit reference to the work of very many investigators They may serve, however, to indicate the lines on which vitamin research has hitherto progressed.

Characteristic of each vitamin is the very small amount in which it exercises its physiological functions, and the circumstance that all are present in very low concentrations in the materials from which they have to be separated has greatly added to the difficulties of their study. It will be admitted, however, that we have now a sound body of knowledge concerning them, establishing their nutritional importance and throwing no little light on their nature. Research in the field is now receiving much help on its constitutional side from modern physical methods, and on its biological side from increasing interest on the part of a large number of clinicians. Vitamin therapy is now joining hands with endocrine therapy, and the League of Nations Permanent Commission on Biological Standards has recognised its growing importance by accepting standards for measures of vitamin activity and defining units in terms of such standards.

Some at least of the conditions which are now grouped as deficiency diseases are of world-wide importance, and though the clear-out symptoms which the experimentalist can observe in animals under strictly controlled conditions are often obscured by intercurrent infections or other complications in clinical cases, yet, once a food deficiency has been recognised as an essential link in the chain of causation, the method of cure becomes in every case as certain as it is logical. On the other hand, once the hygienist has become convinced that this or that disease is really due to faults in the diet of communities, its prevention, with or without administrative action, should be easy to secure. Although a defect in the supply of a vitamin, if serious and continued, may result in actual disease, it is, in Great Britain, more important to realise that a sub-optional supply of any essential food constituent cannot fail to induce sub-normal health which, especially when induced in childhood, may leave permanent disability

Apart from its own inherent importance, the revelation of the significance of vitamins can fairly be said to have directed closer attention to the nutritional importance of other minor constituents of natural foods. The specific needs of the body are proving to be numerous, and lack of materials called for in very small amounts are proving to be just as important to final issues in nutrition as are those required in much larger amounts This applies to the mineral as well as to the organic constituents of food, and ill-assorted diets may be deficient in the former no less than in the latter.

For the progress of scientific knowledge concerning these needs, each separate factor has called, and continues to call, for separate and intensive study ; but the demands of right nutrition need to be viewed as a whole We need to know what should be the ideal balance among the many essentials, and how best to secure that it shall be approached in the food supply of all classes of the community Short of this, we have to-day sufficient knowledge to be sure that malnutrition in its subtler aspects often accounts for disabilities which have hitherto been ascribed to constitutional defects or to other circumstances. With present knowledge, moreover, it should be easy, economic questions apart, to prevent such malnutrition everywhere. There is almost sufficiency in the statement that certain foods often held to be luxuries have to be recognised as necessities for all. Recognition of this bears upon all the problems of a national food supply , upon production, preservation, transport and distribution.

It is interesting to remember that the effective development of the recent knowledge concerning the more subtle aspects of nutrition has been almost co-terminous with the reign of King George.

Structure and Physiological Activity

By JOHN PRYDE, Lecturer in Physiological Chemistry, University College, Cardiff

A SURVEY of the road which the biochemist has trodden during the past twenty-five years reveals a plenitude of milestones whereby the rate and extent of his forward march may be judged The year 1910 was within a short span of the birth of his science , only four years earlier, the *Biochemical Journal* had first seen the light of day The records of this now twenty-nine-year-old journal bear witness to the immense expansion and deepening, during the past quarter of a century, of our knowledge of the laboratories of the living cell, and there are many similar records to be found in other countries New light has come from all sides on the chemical processes of the organism in health and disease, in life and in death Innumerable new substances and previously unknown phenomena have been discovered and added to the ever-increasing physico-chemical complexities of living cells and tissues

Yet despite this immense accumulation of detail, the answers to these persistent questions—"Just what happens in this particular living cell, and how does it happen ?"—seem to elude us Consider for a moment the contraction of a group of muscle cells, surely one of the most universal processes of animal activity In 1907 appeared Fletcher and Hopkins's 62-page paper on "Lactic Acid in Amphibian Muscle", the first really effective attack on the problem of the possible rôle of this acid in the contractile process At that time, lactic acid was the only known 'intermediate' substance supposed to play a part in the phenomenon Now turn to the list of substances, many then unknown, revealed to-day as participating in this apparently simple process—hexose diphosphoric and monophosphoric acids, α-glycerophosphoric acid, phosphoglyceric acid, adenylic acid, phosphoric and pyrophosphoric acids, phosphagen or creatine phosphoric acid, pyruvic acid, methyl glyoxal, glyceraldehyde, dihydroxyacetone, and . . . but who of us is bold enough to write *finis* to this catalogue ? In the numerous attempts to build up the chemical jig-saw here provided, many new and interesting and doubtless important facts have obviously been revealed, but we still seem to be almost as far as we were in 1907 from forming a really comprehensive picture of the sequence of events in a contracting muscle. Indeed one investigator has suggested that all the chemical transformations so far studied are really recovery processes, and do not directly participate in the contractile phase.

The present position of muscle chemistry will serve to illustrate one type of problem which the biochemist is studying in his attempt to provide an answer to the questions already mentioned There are many similar problems Most of them afford as much encouragement as the muscle problem to those who aspire to conquer fresh fields ! There are also, however, problems of a rather different type which likewise concern the biochemist A scrutiny of the records of the investigations here referred to conveys a greater sense of immediate achievement than that which is derived from a consideration of the muscle and similar problems Here we have revealed to us the nature, and in many cases the detailed structure, of compounds of immense physiological potency, compounds some of which determine the issue between life and death, whilst others possess well-nigh incredible potentialities for the well-being, in some cases the ill-being, of living organisms All seem to exercise their functions in the minutest traces, a fact which has added greatly to the difficulties of their isolation and identification, but during the last decade the progress achieved in this direction is highly impressive

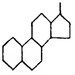
Most of the compounds now to be discussed may be assigned to one of two classes, hormones or vitamins—hormones if they are elaborated within the animal by specific tissues which derive their 'raw material' from the food supply, vitamins if they must be supplied pre-formed in the food-stuffs This classification cannot be applied too rigidly, but it will serve. As we shall see, certain vitamins can be formed by the animal body, from precursors of very closely related chemical structure but devoid of the characteristic physiological properties of the vitamin. In the absence of the vitamin, such precursors assume the rôle of indispensable food constituents To the chemist and the biochemist, the smallness of the amount of these substances which the animal requires is a matter of the greatest interest, but these investigators derive their main sense of achievement in this field from the ability to put down on paper the constitution or structure of the substances concerned. How the substances produce their specific effects is a secret so far guarded by Nature even more efficiently than that of the muscle Nonetheless, science is for the present well content with having established the existence and structure of at least some of these enormously potent

substances upon which animal life depends for its very existence

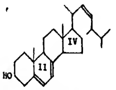
The constitutions of the known hormones or vitamins do not afford, in the absence of empirical information from other sources, *a priori* grounds for deducing their physiological activities, or for differentiating between an active compound and some closely related inactive compound with a structure but slightly different from that of the active one Such *a priori* deductions would necessitate much more fundamental correlations between structure and physiological activity than are yet available But, in actual fact, empirical information is rapidly accumulating, and as it becomes co-ordinated it is found possible to make certain prognostications regarding structure and physiological activity, to suggest, for example, what type of structure is likely to possess a particular activity, and possibly how such activity may be modified when certain substituent groups are added to or taken away from the basic structure

These general considerations are well illustrated by a series of compounds, including both hormones and vitamins, which have in common as a structural basis the condensed benzene ring system which the organic chemist calls phenanthrene The reduced phenanthrene system plus a fourth five-membered carbon ring forms the cholane nucleus, this nucleus is found in the bile acids and in cholesterol and the other sterols One of these sterols, ergosterol, $C_{28}H_{44}O$, when subjected to the action of ultra-violet radiation, undergoes a sequence of transformations, and amongst the products formed under suitable conditions is calciferol, which is isomeric with the original ergosterol Calciferol, which has been isolated in a pure crystalline condition, is vitamin D, the anti-rachitic vitamin essential for adequate ossification and for the control of calcium metabolism in the animal organism The structure of ergosterol is not yet ascertained in all its details, but existing evidence is in accord with the formula shown in skeleton below

Phenanthrene



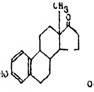
Cholane nucleus



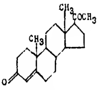
Suggested formula of ergosterol

It would appear that the transformation of ergosterol into calciferol involves the shift of the double bonds in ring II in the direction of the double bond in the side-chain of ring IV. But a final decision cannot yet be reached. The vitamin calciferol may be ingested as such by the animal On the other hand, it may be formed within the animal from previously ingested ergosterol This synthesis *in vivo* of the vitamin from its nearly related precursor has been proved experimentally to occur when ultra-violet radiation impinges on the skin The active rays have sufficient penetrative power to effect the transformation We have here the basis of the curative action in rickets of ultra-violet rays of solar or other origin

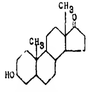
A structure of the cholane type is found in a series of recently discovered hormones possessing remarkably interesting properties. These are the sex hormones which determine the secondary sex characters of animals Three have been definitely characterised, the female follicular hormone or œstrone, the female corpus luteum hormone or luteosterone, and the male testicular hormone or androsterone All three show close structural relationships with each other and with the bile acids and cholesterol, amongst which their biological precursors are likely to be found The accepted structures of the three hormones are given below



Œstrone

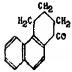


Luteosterone

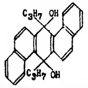


Androsterone

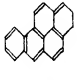
A development of exceptional interest in relation to structure and physiological activity is the preparation by synthetic means of artificial œstrogenic substances, that is, of substances not found naturally, but which possess an activity similar to that of œstrone One of these is 1-keto-1 . 2 · 3 4-tetrahydrophenanthrene, another is a derivative of the hydrocarbon 1 2 . 5 . 6-dibenzanthracene of which further mention will be made.



1-Keto-1.2 3 4-tetrahydrophenanthrene



Derivative of 1.2 5·6-dibenzanthracene



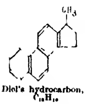
1 2-Benzpyrene

The phenanthrene structure, common to all the substances so far considered, will be seen in the formulæ shown above. These two synthetic œstrogenic substances, it is of interest to note, do not show any androsterone activity.

In the hydrocarbon 1 : 2 : 5 : 6-dibenzanthracene, we encounter one of the very interesting and,

from human standards, very sinister synthetic carcinogenic hydrocarbons. This hydrocarbon produces, when applied to the skin of mice and rats, tumours which can be transplanted and are in all respects similar to malignant cancerous growths. Yet the addition of two *n*-propyl and two hydroxyl groups converts it to an œstrogenic substance![1] Dibenzanthracene is but one of a number of synthetic carcinogenic hydrocarbons. All of these contain the phenanthrene nucleus. Moreover, the long-recognised cancer-producing action of certain tars has now been traced to the presence of a hydrocarbon allied to dibenzanthracene and known as 1 : 2-benzpyrene. It has been synthesised independently of its isolation from coal tar, and the powerful carcinogenic action of the pure substance has been amply confirmed. It is, in fact, the most potent carcinogenic substance so far discovered. It too will be seen to contain the phenanthrene nucleus.

Suggestive and interesting as is the rôle of the phenanthrene nucleus already outlined, three further references are required to complete the tale. First, a series of toxic cardiac-stimulating glucosides is known. These are derived from various plants including those of the species *Digitalis* (foxglove) and *Strophanthus*. The aglucones (that is, the non-sugar parts) of digitoxin, strophanthin and several other closely related substances embody structures of four carbon rings which ally them closely to the sterols. For example, the dehydrogenation of the aglucone strophanthidin with selenium yields the well-known Diel's hydrocarbon, $C_{18}H_{16}$, of which the constitution has been established by synthesis. It has been prepared from several members of the cholane series, and its relationship to this series is beyond doubt. Many other structural details are known concerning the aglucones of the cardiac-stimulating glucosides and in some cases a complete structural formula can be suggested even now. Secondly, mention must be made of the toad poisons, amongst which is the Chinese drug Ch'an Su. These contain structures closely allied to those of the cardiac aglucones, and possess a characteristic action on the heart similar to that of *Digitalis* preparations. Lastly, brief reference may be made to the significant fact that the phenanthrene nucleus is present in some of the most powerful alkaloids, in morphine and codeine of the opium group, in the corydalis alkaloids and in colchicine (meadow saffron).



Diel's hydrocarbon, $C_{18}H_{16}$

Let us leave now these inimical carcinogenic hydrocarbons, toxic glucosides, toad poisons and alkaloids and return to the kindlier theme of vitamins and hormones. From the remainder of our story there stand out two achievements. In both cases the proofs of the nature of the substances concerned—a vitamin in one case, a hormone in the other—have been clinched by syntheses. Ascorbic acid, as the anti-scorbutic vitamin C is now termed, and thyroxine, the iodine-containing amino acid which confers upon the secretory protein of the thyroid gland its specific function as a regulator of the metabolic rate, have both been isolated in a pure state, and both have been synthesised. As a justification for treating these two diverse substances together in this way, we may cite the exceptional brilliance of the work on the synthetic side. The structures are shown below. It will be seen that ascorbic

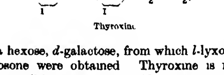
Ascorbic acid

acid is a near relative of the carbohydrates—the starting material used in its laboratory synthesis

Thyroxine

was a hexose, *d*-galactose, from which *l*-lyxose and *l*-lyxosone were obtained. Thyroxine is related to the well-known amino acid tyrosine, and the latter is almost certainly the 'raw material' used in the animal body for its formation.

The case of vitamin A, the growth-promoting vitamin, is especially interesting, since here we have another case of a vitamin which may be taken into the animal body as such, or in the form of a closely related precursor. The precursor is the remarkable, intensely coloured polyene hydrocarbon carotene, with no less than forty carbon atoms. At least four isomeric carotenes occur in natural plant sources, and all appear to give rise to vitamin A in the animal body. Approximately one half of the carotene molecule goes to form vitamin A, which almost certainly has the formula $C_{20}H_{30}O$. The structure of the vitamin cannot yet be regarded as settled, but there is much evidence in favour of that given below.

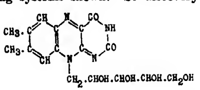


Probable formula of vitamin A

We may end our survey with a reference to advances which are being made in the elucidation

of the structures of vitamins B_1 and B_2. Vitamin B_1 has the formula $C_{12}H_{18}O_2N_4S$. There appear to be two ring systems present; one a glyoxaline or pyrimidine, the other a pyrrole containing a substituent sulphur. Interest in vitamin B_2 has been greatly stimulated by the recent discovery that the flavins, which are yellow water-soluble dyes present in both animal and vegetable sources, possess intense vitamin B_2 activity. The flavins are derivatives of alloxazine, and a substance stated to be identical with lactoflavin of milk whey has already been synthesised. It possesses the complex ring systems shown. So discovery

One of ring systems of vitamin B_1



Lactoflavin

marches onwards! Who shall say what additional structural formulæ will be recorded in a similar survey after the lapse of another quarter of a century?

Diet and Disease

By PROF. STUART J COWELL, Professor of Dietetics, St Thomas's Hospital Medical School, London

THE twenty-five years of His Majesty's reign which are now being celebrated correspond remarkably closely with the establishment of a new era in the science of nutrition. At the opening of the twentieth century, attention was being focused on the quantitative relations of the energy exchanges of the body and on the metabolism within the body of the proteins, fats and carbohydrates of the food. The physiologists and chemists working at these problems were making most valuable contributions to the body of knowledge concerning the processes of nutrition, but such contributions were for the most part not of such a nature as to afford obvious clues either to the origin of or to the treatment of disease. The second decade of the twentieth century witnessed the rapid development of the view that the adequate nutrition of an animal depended on the presence in its food of hitherto unsuspected elements. The absence of such essential elements from a diet was proved to result regularly in the appearance of predictable signs of disease, and the fundamentally new idea of deficiency diseases became gradually established in current medical teaching.

Before mentioning any of the effects which this new conception of nutrition has had on the problems of the prevention and treatment of disease, it will be useful to hark back to the 'pre-Georgian' era to review the current teaching of the medical profession regarding the relation of diet to disease. The fact that faulty diets are often the direct or indirect cause of disease was of course fully recognised, as it had been for many centuries. But there was little precise knowledge available to enable definite diseases to be ascribed to specific dietetic errors. Over-eating was regarded as predisposing to many gastro-intestinal diseases, gout and raised blood pressure, and under-eating was considered to render the body more liable to invasion by harmful bacteria. The idea of lack of balance between the various classes of foodstuffs, for example, relative excess or deficiency of protein, carbohydrate or fat was looked upon as at least an important contributory cause of disease. In the case of scurvy, it was already taught that the absence from the diet of some principle which was present in fresh foods but not in stale foods contributed largely to the production of the disorder. Otherwise the production of disease by faulty diet was largely related to the presence of toxins, pathogenic bacteria or living parasites in food which had become accidentally contaminated.

With regard to the practical dietetic management of diseases now known to be due to specific dietetic faults, the degree of divergence between the methods of twenty-five years ago and of the present day is distinctly less than would have been expected from a consideration of the knowledge available then and now. Specific remedies in medicine have again and again been discovered empirically, and this is true in the realm of dietetics. The treatment recommended twenty-five years ago by at least some enlightened authorities for many of the diseases now spoken of as deficiency diseases would prove satisfactory enough to-day, although such treatment was based on no actual knowledge of the dietetic factors involved. Scurvy was treated by giving fresh fruit and fresh vegetables, rickets and osteomalacia by giving cod liver oil and milk, beriberi by increasing the 'nitrogenous' constituents and diminishing the carbohydrate of the diet—some individuals were even claiming that it could be prevented by adding rice polishings to the diet of highly polished rice which was usually eaten in districts where this disease occurred—and finally pellagra was

to be treated by cutting maize out of the diet.

This list of diseases comprises most of those commonly regarded to-day as vitamin deficiency diseases, and there are not lacking critics of modern nutritional research who profess to be unimpressed by its practical value in clinical medicine because many of its obvious applications had been forestalled by empirical methods of treatment. Such arguments fail to recognise the frequency with which valuable methods of treatment fall into disuse or are replaced at least temporarily by worthless imitations when little or nothing is known of the physiological action of the agents effective in alleviating the symptoms of disease. Thus the value of fresh lemon juice in curing scurvy was known in the eighteenth century, but was forgotten for long periods, and far inferior therapeutic agents were sanctioned by high authorities as late as the present century. Similarly the value of cod liver oil for the cure of rickets had been appreciated for many years before the discovery of vitamins, but this did not prevent the subsequent recommendation of inert vegetable fats as satisfactory substitutes.

It is not argued that empirical treatment has no stable foundation in therapeutics, for clinical medicine still makes use of many old-established therapeutic measures which have as yet no scientific basis. But it is no less certain that the scientific demonstration of a definite cause for a disease offers the best chance for the discovery of satisfactory preventive and curative treatment, and when the cause is proved to be a comparatively simple deficiency in the diet, there should be no excuse whatever for allowing such knowledge to sink into oblivion.

It is now proposed to show how the conception of food deficiencies as a cause of disease has developed during the past twenty-five years. The great stimulus to the remarkable activity shown in this field of medical investigation during this period was undoubtedly the discovery of the vitamins, but the success rapidly attained by those engaged in studying the effects of vitamin deficiencies encouraged the investigation of the effects of other deficiencies, for example, deficiency in the mineral components of the diet, with the result that in such fields also many observations of the greatest importance have been made which have already proved invaluable alike in clinical and in veterinary medicine.

The period of nutritional research which we are surveying had already been heralded by isolated suggestions regarding the importance of dietetic factors other than proteins, fats, carbohydrates and minerals salts for the maintenance of health. Already in 1897, Eijkman had published his experiments on the production of beriberi, which led ultimately to the discovery of the antineuritic vitamin. Hopkins had stated in 1906 his conviction that scurvy, rickets and probably other states of ill-health were caused by unknown dietetic errors the nature of which was bound up with a defective supply of obscure food components. In 1907 Holst and Frölich paved the way for the identification of the antiscorbutic vitamin by producing experimental scurvy in guinea pigs. But it was not until Hopkins had demonstrated in 1912 the fundamental importance of 'accessory factors' in the diet for securing normal nutrition that the idea of specific food deficiencies as a cause of disease began to gain any general acceptance.

It is common knowledge that, since Hopkins's original announcement, the number of accessory food factors or vitamins generally recognised as being concerned in animal nutrition has been steadily increasing, though not all of them have been shown to be concerned in the production of human deficiency diseases. By the end of the first decade of King George's reign, overwhelming evidence had been produced to show that beriberi was produced by deficiency of the water-soluble antineuritic vitamin, xerophthalmia by deficiency of a fat-soluble vitamin, rickets by deficiency of the same or a similar vitamin and scurvy by deficiency of the water-soluble antiscorbutic vitamin. It is not possible to trace in detail subsequent investigations, which have led on one hand to the chemical identification of many of the vitamins and on the other to some understanding of their physiological action. It must suffice to point out how such knowledge has been applied to the prevention and treatment of disease.

In countries such as Great Britain, frank vitamin-deficiency diseases, with the single exception of rickets, are uncommon, but there is increasing evidence that partial deficiencies of vitamins, particularly during the period of growth, are often responsible for sub-optimal physical development, inperfections in the structure of bodily organs and tissues, lowered resistance to certain infective diseases and many vague subjective and objective symptoms of ill-health. It is almost certain, for example, that mild degrees of skeletal deformity caused by faulty feeding in childhood help to raise maternal mortality in childbirth by increasing the mechanical difficulties of labour. The low resistance of the teeth of large sections of our population to decay, with its many sequelæ of chronic disease and ill-health, is due in large part to faulty development of the teeth during the early years of life brought about by dietetic faults, of which vitamin D deficiency is the most prominent. Similarly it has been shown that, in dogs at least, the tendency to the development

of pyorrhœa alveolaris in adult life is largely determined by the supply of vitamin A which was available during the period of growth These few illustrations must suffice to indicate that the original conception of vitamin-deficiency diseases has extended its boundaries to include a variety of diseases attributable to past dietary deficiencies, preventable by suitable feeding during the period of growth

Similar results have been achieved during the period under review by the study of specific mineral deficiency diseases Prominent among those mineral elements deficiency of which in the diet may lead to recognisable symptoms of disease are iron, copper, iodine, phosphorus, calcium and magnesium Lack of sufficient iron in the food has been shown to result frequently in the development of anæmia Such nutritional anæmia is particularly common in infants, and is accounted for by the fact that milk is a poor source of iron The recognition of this form of anæmia has proved to be of considerable practical importance, because it is often associated with an increased susceptibility to many of the common complaints of infancy and can be corrected with great ease The enormous amount of work that has lately been carried out on the relation between iodine deficiency and the development of goitre has not yet completely solved the problem of the causes of thyroid enlargement, but it has certainly provided very successful methods of wholesale prophylaxis in districts where goitre is endemic Lastly may be mentioned the revolution in the cattle-rearing industry of South Africa which has followed the discovery of phosphorus deficiency as the immediate or ultimate cause of serious losses in this branch of agriculture.

There can be no question that already the modern conception of nutrition has produced practical results of immense significance in both preventive and curative clinical and veterinary medicine The results are not confined to the prophylaxis and treatment of diseases which arise as the result of actual deficiencies in the food supplied They have already been extended to include the treatment of diseases in which defects in the absorption or utilisation of particular food elements rather than faulty diets are responsible for the development of co-existing signs of deficiency diseases The term 'secondary deficiency disease' is now being used to distinguish this particular class of nutritional disorder In this group might well be placed that once fatal malady pernicious anæmia, which the brilliant researches of the past decade have shown to be amenable to simple dietetic treatment, although there is no evidence that dietetic errors play any part in its causation As more and more precise information is gained concerning the intimate processes of metabolism within the body, there should be increasing opportunities of preventing and successfully treating disease by adjusting the diet to influence those metabolic processes which may produce the symptoms of disease when they deviate from their normal course This has long been one of the aims of clinical medicine, its ultimate realisation has surely been brought one stage nearer fulfilment by the nutritional investigations of the past twenty-five years

---

Viruses as the Cause of Disease

By DR JOSEPH A ARKWRIGHT, F R S, Lister Institute of Preventive Medicine, London

AT the end of the nineteenth century, a new category of infective agents was discovered which are now classed as viruses, in the modern sense of the word The chief property which unites them, and by which they have been distinguished from previously known minute parasites, is the extremely small size of their component particles, since these are smaller than bacteria, and many of them are not visible even with the highest powers of the microscope Until quite recently, it was customary to speak of all viruses as invisible, but in some cases the minute granules of which the virus appears to consist can be clearly seen, when stained, by direct microscopic observation; but in most cases they cannot be distinguished by their shape, but only by their uniformity, numbers and their source in special parts of the diseased tissues. The recent investigations by Barnard with the ultra-microscope and photomicrography by ultra-violet light have added to our knowledge of their size and form

A special feature by which the invasion of the cells of the host by many viruses can be recognised is the occurrence of 'cell inclusion bodies'. These forms, of which there may be one or more in a single cell, vary in size and may be larger than the nucleus. Opinion as to their nature has undergone various vicissitudes. After their discovery, when they were at first hailed as protozoal parasites, they were for long regarded as merely reaction products of the cell protoplasm to the presence of the virus, a position now favoured for the 'inclusion bodies' associated with virus diseases of plants. More recently it has been shown that in some virus diseases of animals these 'inclusion bodies' consist of masses of the minute filterable

forms of 'elementary bodies' held together by a soluble matrix These bodies have been most completely and fruitfully studied in fowl-pox, small-pox, vaccinia, ectromelia—a disease of mice—and psittacosis, the infective disease of parakeets which also attacks man

The list of diseases of man and animals due to filterable viruses is continually being increased, and considerably more than fifty are now known, their study has been intensified and especially productive during the last fifteen years

The original recognition of the existence and importance of these agents was due to the use of earthenware and porcelain filters which retained the smallest bacteria When tissue extracts or secretions from an infected animal were passed through such filters, the filtrates were shown to be infective and capable of reproducing the disease in a fresh animal, this process could be repeated indefinitely, proving that the active agent multiplied in the animal body and was not merely a chemical substance or toxin The virus of foot-and-mouth disease, the first shown to cause a disease of animals, was discovered in 1898 by Loeffler and Frosch It passes through finer filters than any other known virus, so that no question of visible particles has arisen, since massed granules or inclusion bodies have not been observed The most essential qualifying characteristic of a virus has ever since been its filterability.

Most viruses remain active after being dried over sulphuric acid, and some are more resistant to alcohol and certain other disinfectants than bacteria Many viruses are present in the tissue juices in high concentration, and such suspensions in liquids can still prove infective when diluted 1 in 10^8 or 1 in 10^9. The resemblance in many respects of a virus to an excessively minute bacterium has led to the belief in their similar nature which is now held by most pathologists It must be admitted, however, that part of the argument is based on analogy, since viruses cannot be subjected to the same tests as bacteria to prove that they are living agents causing disease

Besides the small size of the ultimate particles of a virus and the resulting absence of a recognisable differentiating morphology, there are certain other peculiarities distinguishing these two classes of agents. Bacteria, with few exceptions, can be propagated on sterilised artificial culture media, and can be obtained in pure culture by the method introduced by Koch of selecting single colonies grown on a solid sterile medium. By this means their infective and other activities can be examined without the risk of contamination with substances derived from the host. A virus, on the other hand, in most cases requires the presence of living cells of the host to enable it to multiply, and it often appears to grow only or chiefly inside the cells of the animal tissues. Artificial culture of a virus can, however, very often be maintained in pieces of animal tissue kept alive and growing apart from the body The virus of fowl-pox, vaccinia or vesicular stomatitis of the horse and of some other diseases can also be propagated in the living embryo in an incubated hen's egg.

The fact that tissues of a host are needed to enable viruses to multiply has led to the suggestion that the virus may not necessarily be alive but may only serve as a stimulus to the host cells, causing them to reproduce the virus, and that the particles seen in a suspension containing a virus and indeed the virus itself are really products of the host

This suspicion has been especially strong in the case of the infective transmissible sarcoma of fowls described by Rous, which can be reproduced by injecting a filtered cell-free extract of the diseased tissues into a normal fowl The resemblance of avian sarcoma to other virus diseases extends to the recognition by Ledingham and Gye, by the use of the high-speed centrifuge, of minute particles resembling those of other viruses The nature of these particles was moreover confirmed by their reaction (agglutination) with the blood serum of animals which had been injected with the sarcoma, in the same way that similar reactions have been demonstrated with the elementary bodies from other virus diseases

The resemblance in structure and behaviour of the sarcoma of fowls to the malignant growths of mammals gives rise to hesitation before admitting that it is caused by an extrinsic virus, since mammalian malignant tumours have never been found to yield an infective cell-free extract and have been usually regarded as due to intrinsic tissue changes, though both mammalian and avian sarcomata can be induced by external physical and chemical irritants, such as tar and certain other substances

If therefore an extrinsic virus is one of the essential causes of fowl sarcoma, it must already be present in every susceptible fowl The view that viruses which produce disease are not essentially invading parasites, but are produced by the host, is opposed by the regularity with which diverse viruses can be propagated in the same kind of animal, and by the fact that the same virus may infect several widely different species For example, there are three distinct types of foot-and-mouth disease virus which produce apparently identical symptoms in animals and can only be distinguished by the fact that any one does not protect an animal against infection with the other two; nevertheless, each virus maintains its identity whether propagated in the cow, pig,

guinea pig, rat or hedgehog. It is difficult to see how this could happen if the virus were produced by each species of mammal from its own tissues.

Another filterable agent, in many respects resembling the virus of an animal disease, is the bacteriophage, which was independently discovered by Twort and d'Herelle. The effect of a drop of a suspension of bacteriophage added to a young liquid culture of susceptible bacteria is that the latter are dissolved and a large amount of fresh phage is produced The bacterium-free filtrate of the liquid culture may often be diluted ten million times and still the same effect be produced by a drop as by the original suspension

D'Herelle and many other bacteriologists believe that the phage is a living agent which infects young growing bacteria, multiplies in their interior, and is set free when the bacteria die and break up

Phage, though destroyed at a temperature of 70°–75° C, as a rule survives at 60°–65° C, when the bacteria with which it is associated are killed, it also resists drying and is remarkably resistant to the action of alcohol, acetone and chloroform. D'Herelle considers that all strains of phage are really one, though different strains become adapted to different bacteria, but more probably many phages when first obtained are a mixture of distinct races, and most filtrates containing phage are in the first instance derived from sewage or fæces, containing a great variety of bacteria

Some strains of bacteria harbour a phage although apparently insusceptible to its destructive action The activity is only manifested when a filtrate is tested on another susceptible strain Thus many bacterial cultures have been shown to produce phage, though the presence of phage is not apparent and may not even have been suspected This phenomenon suggests the original production of the phage by an uninfected culture, but it may merely be another instance of an apparently normal organism 'carrying' a parasite; many parallel cases are known of animals and plants 'carrying' infective agents whilst themselves unaffected De Jong showed that cultures of certain sporing bacilli which produce a phage may still be 'lysogenic' after being heated at 100° C. for five minutes, whereas the free phage is killed at 70° C. for five minutes When the spores germinate the phage is again liberated. This experiment suggests that the phage is preserved by its inclusion in the resistant spore, and this evidence of its derivation from the germinating spore *de novo* is not conclusive

The chief reason for doubting the living nature of some phages and certain viruses is the very small size of their filtrable particles, which makes it very doubtful whether they can have a complex composition resembling that of other living things.

Different strains of phage are very unequal in their filterability; some have relatively large particles with a diameter about half those of vaccinia, while others pass through very fine filters, like the virus of foot-and-mouth disease, for which the diameter is estimated at about one tenth of the coarser phages

The uniform and carefully graded collodion membranes introduced by Elford, of which the average pore diameter can be calculated, enables much closer estimates to be made than formerly of the size of particles which just pass or are just withheld The size of the particles of some viruses has also been calculated, especially by Bechhold, by their rate of deposition when centrifuged at 10,000–15,000 rev per min

It has been possible to purify virus particles by first filtering and then centrifuging at high speed, washing the deposit and again centrifuging, as has been shown by Ledingham

By the new collodion ultra-filters the diameter of the particles of different viruses has been estimated to vary from 200 mμ to 150 mμ for vaccinia to about 8–10 mμ for foot-and-mouth disease (μ = mikron = 1 thousandth of a millimetre, mμ = one thousandth of a mikron) It is difficult to understand how with such dimensions they can have a composition of sufficient complexity to consist of living matter For comparison, the smallest bacteria have a diameter of 1 0–0 5 μ and the egg-albumen molecule has been estimated at 4 34 mμ diameter

Doerr, in a recent treatise, while granting that some viruses have been shown to be living, denies the possibility of life in those of the smaller dimensions. It so happens that the viruses of foot-and-mouth disease and louping-ill, which are among those with the smallest particles, exhibit all the typical essential characters of viruses both *in vitro* and in the animal body, though causing very different diseases and having very different 'life-histories'.

The exact and quantitative experiments with filters have been made possible by the high concentration in which certain viruses occur, and by opportunities for determining the presence of the virus in different dilutions by inoculation of susceptible small animals The dilution of some fluids containing virus from the animal body can be carried to 1 in 10^6 or even higher when dealing with foot-and-mouth disease, vaccinia and some other diseases without depriving them of infectivity.

The quandary arising from the very active and apparently vital functions of virus particles in spite of their small size raises the question whether the accepted definitions of life are universally applicable or whether some intermediate state

between what is called living and dead matter may not exist, as has been suggested by Boycott.

Of the functions usually postulated for a living organism, assimilation appears to be the most characteristic and indispensable. It is reasonable to assume that the metabolism of an organism would be much simplified if it existed in a circulating medium which provided a constantly changing supply of materials resembling its own components, such as might be afforded for an obligatory parasite living inside the cells of its host. Such an existence would have very different requirements from a truly independent life.

Virus diseases are transmitted from one animal to another by very varied means. Some, like canine distemper and certain influenza-like diseases of man, by droplets in the breath, others like yellow and dengue fevers by the bites of insects, others like louping-ill of sheep by the bites of blood-sucking ticks or of mites; again, the bite of the mammalian host is the usual mode of infection with rabies, but for many others the method of transmission is still uncertain. In these respects they do not differ from diseases due to bacteria.

It is characteristic of many diseases that, although the initial infection is caused by a virus, many of the symptoms and complications are due to secondary infections with bacteria, and this is notably the case in the influenza-like group in man, in swine fever, canine distemper and swine influenza.

A virus may become remarkably adapted and sometimes permanently attenuated, when transferred to a new host, as is well instanced in the change of the virus of small-pox to vaccinia in cattle and rabbits, and of the rabies virus in the rabbit.

The period of resistance shown by the host following an attack of disease is sometimes very prolonged, even lifelong, after small-pox, varicella, yellow fever and canine distemper, but in some other cases the protection afforded is of comparatively short duration, in foot-and-mouth disease usually for one to two years, whereas frequently recurring attacks due to the virus of *Herpes labialis* are common.

This immunity is to a great extent due to the production in the animal body of 'antibodies' which can be found in the blood serum of recovered animals, just as occurs after bacterial infection. These antibodies can often be demonstrated by the formation of a precipitate or by the agglutination of the virus particles when a suspension of the elementary bodies is mixed with the serum, or by the neutralisation of the virus by the serum when both are injected into an animal. These phenomena are of the same kind as the precipitation occurring when the blood serum of an animal which has been inoculated with a foreign protein (antigen) is mixed with the same protein *in vitro*, and are not peculiar to true infections.

It is not intended here to do more than refer to the enormous and increasing number of filterable viruses known to cause infective disease in plants and found in their juices. These, like mosaic disease of tobacco, spotted wilt of tomato, and crinkle and leaf-roll of potato, may cause very serious disease, or in other cases may be present throughout the plant without producing any visible effect, as in some infections of the potato.

There is good evidence that two viruses may co-exist in the same plant, and as a result the symptoms may be either much more or much less severe than when either virus is present alone.

Some viruses are transmitted by insects such as aphis or thrips, while others pass by unknown means. In some of these diseases of plants peculiar 'inclusion bodies' are found in certain cells, but their relation to the virus is undetermined. It is known that these 'bodies', as well as some of the symptoms due to a virus, can in special cases be imitated by the addition of certain inorganic salts to the soil, but the disease is not then transmissible. Some plant viruses are highly resistant to drying, chemical action and alcohol, and in many ways the viruses of plants resemble those of animals.

The problems which the behaviour and properties of viruses raise are of great practical and theoretical interest, and are by no means yet solved.

Heat Production of Muscle and Nerve

By PROF. A. V. HILL, O.B.E., F.R.S., Foulerton Research Professor of the Royal Society

THE first paper by the present writer on this subject was printed almost exactly twenty-five years ago in the *Journal of Physiology*: the coincidence reinforced the invitation of the Editor of NATURE to write an interim report.

The heat production of muscle had been investigated in the past by such scientific giants as Helmholtz, Heidenhain, Fick and Blix; and indeed it was with Blix's apparatus, purchased by the providence of Langley and set in order by the Cambridge Instrument Company in the days of Horace Darwin and Keith Lucas, that the present experiments began. For some time, apart from Blix's work on the relation between heat

production and muscle length, little of importance had been done on the subject; but, as Langley wrote in a letter dated November 11, 1909, "an especial problem" had been "suggested by Fletcher and Hopkins's work on the efficiency of the muscle working with and without oxygen Once started, there are plenty of further experiments to do" The indication was clear and in 1912 it was shown that a considerable part of the heat set free by an active muscle "occurs in recovery processes—presumably in the oxidative removal of the lactic acid liberated during contraction" The recovery heat production of muscle has been a fruitful subject of investigation in the intervening years; the most recent papers have pushed its analysis to the extreme case of a single twitch in which, in a muscle of about 0·1 gm, 0 0002 calorie is liberated in the fifteen minutes following contraction

The 'initial' heat production—that which occurs during actual contraction—has been extensively explored Its investigation has led to great improvements in technique, for not only its amount but also its distribution in time relative to the various phases of mechanical activity had to be determined The former demanded calibration of the thermo-electric apparatus, together with the muscle, in absolute units of heat the latter, great rapidity in recording. The heat had to be related to the force developed and maintained, to the work done, to the character, the duration and the frequency of the stimulus, to the temperature and to the physico-chemical condition of the muscle It was shown quite early (1914) that the initial heat, and its relation to force developed, are independent of the presence of oxygen, so that the chemical processes of contraction were presumably of a non-oxidative character This fact has a fundamental bearing on the nature of muscular fatigue of the rapid 'athletic' type: as also has the behaviour of the delayed oxidative heat production on recovery from such fatigue: but that is another story.

In 1912 the first attempt was made to relate the heat associated with the process of muscular activity to the only chemical events then known to occur. the formation and subsequent removal of lactic acid and the production of carbon dioxide It was clear at once, as has been abundantly verified since, that the lactic acid was not removed simply by oxidation—the heat was far too small. In 1913, Peters published the first direct comparison of the initial heat with the lactic acid set free, and from 1919 onwards Meyerhof and his colleagues have made full use of the relation between heat and chemical change in their exploration of the intermediate mechanism of contraction. Lactic acid is no longer the only chemical substance known to be liberated in activity: creatine-phosphoric acid breaks down, and a complex sequence of phosphate changes has been discovered It is probable indeed that the primary energy change in muscular activity is not lactic acid formation at all, and that the latter process is really the first stage in restoration, a non-oxidative stage rather rapidly completed, and followed (if oxygen be present) by the oxidative processes of recovery referred to previously Here again the heat has thrown light on the problem, since, even in the complete absence of oxygen, a significant amount of heat is set free in the first minutes following muscular activity

From the general scientific point of view, apart from the details of chemical machinery, the following broad conclusions may be drawn:

(i) The muscle is not a heat engine, but a chemical engine working at practically constant temperature.

(ii) It possesses an 'accumulator' mechanism by which energy can be liberated very rapidly without oxidation, and a 'recharging mechanism' by which the *status quo* can be restored under the influence of, and at the expense of energy derived from, oxidation.

(iii) It is primarily a machine for developing and maintaining force, not for doing work: even if no work is done, the muscle contracting at constant length, even if negative work is done as when a muscle is stretched during contraction (for example, in walking downstairs), considerable heat is liberated, more the greater the duration of contraction. It is true, as Fenn (1923) found, that there are significant relations between work and heat, but these do not disguise the fact that the primary relation between thermal and mechanical effects is one between heat and force developed and maintained

(iv) The 'efficiency' of the muscle machine, considering the whole cycle of breakdown and recovery, that is (work done)/(total energy set free) could never be greater than about 50 per cent, since the recovery process frees about as much energy as the initial process, and the latter always shows a positive balance of heat, even when maximal work is done Under actual working conditions in man the maximum 'efficiency' is about 25 per cent. The energy is derived ultimately from the oxidation of foodstuffs

(v) Little is yet known of the means by which 'excitation' induces chemical change and the latter mechanical effects. The existence (in some muscles) of optical phenomena running parallel with the thermal and mechanical changes, and the alterations of apparent viscosity during contraction,

strongly suggest that the ultimate cause of the mechanical effects is a reversible rearrangement in a system of large protein molecules, on which X-ray analysis, or the methods of surface chemistry, may ultimately throw light

A not unimportant result of work on the heat production of muscle has been the enforced improvement of galvanometers and of thermopiles of the insulated type This has had some interesting by-products, for example, (i) a sensitive method for measuring the slow resting heat production of a small object, (ii) a method of determining the vapour pressure depression of a small quantity of solution (down to 0 1 mgm) to an accuracy considerably better than 1 per cent, (iii) the possibility of further progress in studying stresses in engineering structures by means of their thermo-elastic properties, (iv) a method of increasing galvanometer sensitivity by the use of a photo-cell

Most important, however, from the point of view of physiology, has been the work on the heat production of nerve It was formerly believed that a nerve transmitted its messages without loss of energy, that the nerve impulse was in some sense analogous to a mechanical or electromagnetic wave in which all the energy involved is put into the system at the start Unsuccessful attempts to measure the heat production of stimulated nerve supported this point of view. As a matter of fact, it is quite wrong the heat is very small, but it is measurable and it obeys certain quite definite rules. In the transmission of a single impulse in medullated nerve, there is an 'initial' production of heat of 2×10^{-6} to 8×10^{-6} calorie per gram of nerve, and a recovery heat production of ten to thirty times that amount. The time-course of the latter, occupying 10–30 minutes (at 20° C.), has been mapped out · the relation of the former to temperature, frequency of excitation and other factors has been determined.

The results have been confirmed by measurements of the oxygen consumption, and attempts have been made to determine the chemical changes underlying the transmission of the nervous impulse. These latter have not, as yet, had much success, owing to the extreme smallness of the quantities involved. It is probable that the first stage in nerve transmission is the building up at each point of a critical electrical potential, under the influence of the electric accompaniment of the impulse approaching from a distance When the potential reaches its critical value at any point a state of instability of unknown nature results, the insulating properties of the nerve boundary change, and the potential difference normally existing at that boundary is now able to produce a current to neighbouring regions: these in turn are similarly activated and the wave is propagated The nerve boundary then returns to its normal insulating state The initial heat is presumably due to the chemical events associated with this cycle of membrane changes as in muscle where, with 100,000 times as much heat, chemical changes are associated with contraction and relaxation The recovery heat may be due either to an oxidative reversal of these chemical changes, or to the restoration of the ionic differences responsible for the resting potential difference across the nerve boundary

For the moment, there is a lull in these measurements of heat in muscle and nerve further progress is probably to be sought chiefly in other directions. Micro-chemical methods need to be greatly improved if the chemistry of nerve activity is to be understood, the physical chemistry of the active boundaries involved in nerve transmission requires an application of the new technique of surface chemistry, the electrical accompaniments of excitation and transmission need more accurate quantitative study On the muscle side, owing to the greater magnitudes involved, the chemistry is not so difficult, and considerable light is being thrown, and a very complex system is being revealed, by biochemical methods The newer methods, however, of optical and X-ray analysis need to be more fully tried before one can say how far alteration in complex molecular systems will be found responsible for the mechanical accompaniments of activity The effects of high hydrostatic pressure on the behaviour of muscle and nerve, and the changes of volume accompanying contraction, also may throw light on the mechanism

These researches have been due to the co-operation of many Langley started them on the suggestion of Fletcher and Hopkins's work. Burker and Paschen, in respect of thermopiles and galvanometers, gave fundamental help R. A Peters, Weizsäcker, Parnas and Lovatt Evans collaborated before 1914 Hartree for many years bore the brunt of the experiments (and the arithmetic!) on the analysis of muscle heat into its constituent phases Downing similarly contributed his skill in the construction of delicate instruments The work of Meyerhof, of Embden, of Parnas, of the Eggletons, of Lundsgaard and of many others brought light from the chemical side. Fenn's fundamental researches on the relation between work and heat have been, and Gerard's on the subject of nerve metabolism must be, recorded Azuma, Ernst Fischer, Gasser, Parkinson, Cattell, Furusawa, Wyman, Bronk, Bozler, Feng, Levin, Cowan, Bugnard, Rosenberg, each furnished a characteristic contribution. The list is not exhaustive In spite of the

present lull, at any stage in further progress reference may have to be made once more to the so-called 'myothermic' and 'neurothermic' methods, which have so great an advantage in their quickness and sensitivity, and in the fact that they can determine so fundamental a quantity as the total energy without any injury to the experimental object The usefulness of these methods will probably not end with the jubilee of their revival

Therapeutic and other Applications of X-Rays and Gamma-Rays

By Dr. G W C KAYE, O B E, National Physical Laboratory

WITHIN a period of fifteen years prior to the King's accession, Rontgen had discovered the X-rays and J J Thomson the electron, Becquerel had discovered radioactivity and the Curies had isolated radium The new reign was to prove an era of X-ray and radium research no less fruitful than its predecessor In particular, the X-ray crystal diffraction experiments of Laue in Germany in 1912, followed by those of the Braggs in England, opened up a new vista of research which has left its mark on physics, found diverse and important applications in industry and is beginning to acquire significance in the biological sciences Rontgen, who had lived to see many of these developments, died in 1923 in his seventy-eighth year, poor in fortune, but consoled by the beneficent services which his discovery had rendered in the War

The British Army entered the War relying entirely for its X-rays on induction coils and 'gas' tubes, both well-nigh obsolete now About 1908, Snook developed the high-tension closed-core transformer with rotary-arm rectifier, and in 1913, Coolidge introduced the hot-cathode X-ray tube Much development has since followed The X-ray tube of to-day is self-protected and shock-proof, and is even claimed to be climate-proof! The complete equipment is earth shielded, permits precise control and is silent in operation The high-tension transformer works in conjunction with one or other of the rectifying-valve and condenser circuits, which deliver either pulsating or constant high voltage to the X-ray tube. In routine medical radiology, these voltages range from 60 kv. to 200 kv , but 400 kv and up to 1,000 kv are now to be found in certain therapeutic centres.

In 1910, X-ray diagnosis was fairly well advanced, but radiation therapy was in its infancy. Protection for the worker was rudimentary or non-existent, and many injuries and deaths resulted. Not until 1921 were the British protection recommendations issued by a representative committee, and these, the first in any country, were used as a basis for international agreement four years later at Stockholm. These recommendations, which are revised triennially by an International Protection Commission, have been adopted throughout practically the whole civilised world They have not only provided effective safeguards against the working dangers of X-rays, but also have contributed, as no other factor has, to the better housing and general well-being of the X-ray and radium worker Most radiology departments in 1910 were deplorably housed, whereas the light, roomy and well-ventilated departments of to-day are often a source of pride to hospitals

Another vital step in the progress of radiation therapy was the adoption of the rontgen (r) as the international unit of X-ray quantity or dose The röntgen, which is an air-ionisation unit, was the subject of an international inter-comparison in 1931 by the national laboratories of the United States, Germany and Great Britain, a very satisfactory measure of agreement resulting It is probable that the röntgen will be adopted internationally for gamma radiation also, though further measurements on both gamma and high-voltage X-radiation are required.

Radiography has found considerable application in the industries and arts, for example, in the examination for flaws and other defects in metal castings and forgings, welds and assembled components Wooden aeroplane parts were examined radiographically in the War Many millions of clinical thermometers under test have been expeditiously scrutinised at the National Physical Laboratory by the use of X-rays during the last ten years. Other industrial applications include the screening of electrical insulators and golf balls during manufacture The National Gallery and the Courtauld Institute have recently installed X-ray outfits for the examination of pictures and objects of art. Gamma-rays are resorted to in the radiography of metal specimens too thick for X-rays to tackle.

It is, however, in the world of medicine and surgery that X-rays and radium have been turned to account most outstandingly. X-ray diagnosis has improved in the last twenty-five years to an almost spectacular extent, and radiation therapy, though of more recent growth, has now established its claim to an important place in the treatment of malignant disease. The use of radium for cancer treatment was given impetus in Great

Britain by the formation in 1929 of the National Radium Trust and Commission, which were constituted to distribute and administer some quarter of a million pounds worth of radium which, it will be remembered, was subscribed for as a national thanksgiving for the King's recovery from his illness. The Trust and Commission were given powers by their Charter not only to augment existing supplies of radium for the treatment of the sick, but also to advance existing knowledge of the best methods of rendering such treatment

I would here mention that in what follows, I have had the advantage of the experienced and authoritative assistance of Dr Constance Wood, whose responsibility for the medical opinions expressed I gratefully acknowledge

While it is still the case that the whole of the gastro-intestinal tract and early carcinoma of the breast are best treated by surgery, X-ray and radium therapy is bidding fair to displace the knife in the treatment of certain other forms of cancer The response of tumours to radiation demands wide study, each type of tumour having a different response, both clinically and histologically Views on radiation treatment have changed and the single massive dose of X-radiation, formerly advocated at Erlangen, is now replaced by a sequence of smaller doses spread over a period of time

As to the quality of radiation required, this depends on circumstances In certain superficial forms of cancer, such as rodent ulcer, almost any type of radiation will produce healing, whether it be low-voltage X-rays (for which high-power close-proximity tubes are now available) or the beta- or gamma-rays of radium Other types of cancer, such as squamous epithelioma of the skin and lip, are successfully treated by a few milligrams of heavily screened radium, the residual scar frequently being quite invisible

The real problem of malignant disease lies, however, in the treatment of glandular metastases Small quantities of radium or low-voltage X-rays are not capable of destroying cancer cells at a depth ; for the deeper lesions and gland areas we turn either to (*a*) X-rays which, excited by very high and ever-increasing voltages, tend to approach gamma-rays in quality, or to (*b*) large quantities of radium placed at distances remote from the skin in an attempt to obtain the large depth doses possible with X-rays Both methods have their advocates. From a financial point of view, Regaud estimates that when the heavy initial cost and low maintenance costs of a large radium unit are balanced against the lower initial cost and higher running costs of a high-voltage X-ray plant, there is little to choose between them at the present price of radium, though the possibility of an induced radioactive element of sufficiently long life to make its use practicable may perhaps be envisaged. Adequate protective arrangements appear to be possible with either radium or high-voltage X-rays

The early progress of 'teleradium' was slow, and its ultimate value is a matter on which opinions differ, but the growing belief in its efficacy by those who have had experience is reflected in the rapidly increasing number of large radium units being set up in the world Paris, which has had a 4 gram unit for some eight years, now has an 8 gram unit Stockholm has a 5 gram unit in addition to one of 3 grams which it has used during the last six years , New York, Chicago, Buffalo and Toronto each has a 4 gram unit Great Britain has lagged behind somewhat in its recognition of the value of 'bomb' treatment, partly because cases are not referred for radium treatment at as early a stage as in many parts of the Continent There have, however, been 1 gram units at the Cancer and Westminster Hospitals in London since 1929, while the Radium Commission in 1933 allocated 1 gram units to both these hospitals as well as to Middlesex and University College Hospitals Edinburgh and Leeds now have also 1 gram units The Radium Beam Therapy Research Board, set up with State support in 1933, is working with a 5 gram unit since 1933

In X-ray diagnosis, short-exposure radiography of any part of the human body offers no difficulties to the experienced With improvement in apparatus and technique, less and less dense bodies can be distinguished, until now the soft tissues and even the extent of tumour growths in them can be depicted Modern fluorescent screens enable digestive movements, heart beats or lung movements to be watched or cinematographed

The physiology of the stomach and alimentary tract has been transformed The presence and extent of internal cancerous growths or small ulcers in the stomach can be definitely established by swallowing barium salt preparations which are opaque to X-rays Extraordinary anomalies, such as the presence of the stomach in the chest, have been so revealed. Much work has been done recently on the injection of opaque fluids into abnormal tracts, the radiographs clearly demonstrating to the surgeon what difficulties and dangers may be encountered in a projected operation. Some organs, for example, the gall bladder and parts of the kidney tract, have the property of concentrating certain administered liquids so that they presently become opaque to X-rays, and thus outline the organs and facilitate the diagnosis of deep internal disease

The X-rays assist in demonstrating the extent of involvement and the type of disease in tuber-

culosis of the lungs In the treatment of tuberculosis, when by the introduction of air into the chest cavity, the lung has been collapsed to allow it to rest and heal, radiography indicates the state of the lung and when it should be collapsed again Pathological cavities in the substance of the lung are revealed by introducing into the chest lipiodol, which is an oil rendered opaque by iodising it Radiography is a valuable aid in the study of heart disease The heart is sometimes unexpectedly shown to be on the right side of the chest In radiography of the brain, air may be introduced into the cavities of the brain, so locating and outlining in the radiograph the extent of a tumour and consequently indicating where the surgeon must operate

The fine trabecular structure of the interior of bones is plainly revealed by the X-rays Difficult fractures are set under the fluorescent screen, thus assisting in producing perfect restoration of the damaged bone The development of the human embryo is better understood, and radiographs of the unborn child show the centres of the ossification of the bones before birth and are often of invaluable assistance to the obstetrician

The X-ray localisation of foreign objects in the body is a routine matter in hospitals, which are called upon to deal with an amazing variety of objects, for example, coins and safety-pins swallowed by children, dental plates inadvertently swallowed, nails, screws, safety razors, etc, deliberately swallowed by prisoners and others, and legacies from the War in the shape of buried bullets and shrapnel

Genetics Since 1910

By PROF J B S HALDANE, F R S, Professor of Genetics, University College, London

THE state of genetical knowledge in 1910 can be learnt from Bateson's "Mendel's Principles of Heredity", of which the first two editions were published in 1909 and 1913 The principles which Mendel had shown to hold for seven contrasted pairs of characters in *Pisum* had been extended to a very large number of characters in many plant and animal species, including man The main additions to these principles were the pure line, multiple allelomorphism, partial linkage between genes, epistasy, and one of the four types of sex linkage now known The latter discovery, along with cytological work, had made the genetics of sex determination fairly clear At least one case of extranuclear inheritance had been recorded

Mendel's theory was based on the hypothesis that a (diploid) heterozygote produced two kinds of (haploid) gametes in equal numbers. This has since been proved in cases where the haploid generation has a number of variable characteristics, notably by v. Wettstein in mosses, or where individual haploids can be bred from, as by Andersson-Kotto in ferns In such cases it is found that the products of a single meiosis are always exactly two cells carrying one member of an allelomorphic pair and two carrying the other. When several pairs are segregating, four different haploid types may arise, and a further analysis shows that genetic segregation may be associated with either meiotic division.

The cytological basis of genetics was cleared up by Morgan and his colleagues Bridges, Muller and Sturtevant, working on *Drosophila melanogaster*. They were able to show that the genes were located at different points on the chromosomes. Adequate chromosome maps exist for several species of *Drosophila*, and, thanks largely to the co-ordinative work of Emerson, for *Zea Mays* Less complete maps exist for *Lathyrus* (Punnett) *Pharbitis* (Imai) and other plants By studying the giant chromosomes of the gland cells in *Drosophila*, Painter has been able to correlate the theoretically derived gene map with visible structure, and Muller and Prokofieva have detected visible changes associated with a difference affecting a single gene. Using chromosomes which were microscopically distinguishable owing to the attachment of sections of other chromosomes to them, Stern found that the visible changes in any individual could be predicted from its genetical constitution Thus crossing-over is a physical fact as well as an explanation of genetical phenomena

Similarly, Darlington has shown that there is a quantitative agreement between microscopically visible chiasmata and genetically detectable crossing-over, and has made it probable that these two events, which are really aspects of the same phenomenon, are both due to the relief of strains produced in the chromosomes by coiling. Equally striking is the cytological evidence that abnormal types of linkage are associated with cytologically visible exchanges of parts between different chromosomes (Muller and Altenburg, Hammarlund and Hakansson, Dobzhansky, McClintock, etc.).

Oenothera Lamarckiana and other forms which breed nearly, but not quite, true, have been shown to be examples of permanent heterozygosis. Here the organism forms two kinds of gametes, but only one of the three possible combinations is produced, owing to inviability or competition.

The genetical analysis of *Oenothera* is mainly due to Renner, while Cleland, Darlington and other workers have elucidated its cytological basis, on principles largely suggested by Belling's work Meanwhile Muller built up and analysed a *Drosophila* which behaved like *Oenothera*, possessing balanced lethal genes in two homologous chromosomes

The genetics of polyploids are now understood Gregory studied the genetics of the autotetraploid *Primula sinensis*, which contains four similar sets of chromosomes, and Winge pointed out that hybridisation might lead to an increase in the number of chromosome sets The distinction between autopolyploids with more than two similar sets of chromosomes, and allopolyploids with several unlike sets of pairs derived from different species, was made by Kihara and Ono, while R E Clausen and Goodspeed, Newton and Pellew, and many other authors analysed allopolyploids Müntzing, by his synthesis of *Galeopsis tetrahit* from *G pubescens* and *G speciosa*, was the first to prove that Linnean species had arisen by hybridisation and doubling of the chromosome number The gradual discovery that most cultivated plants are allopolyploids has given this work great practical importance

The origin of new genes by mutation was a rare and uncontrollable process until Muller showed that it could be speeded up at least two hundred times by X-rays Mutations generally lower the viability of an organism, but may raise it (Timoféeff-Ressowsky). They are generally recessive, but sometimes dominant They are at least sometimes reversible by a further dose of X-radiation, and therefore cannot be regarded as mere injuries They can also be provoked to a slight extent by heat, while the possibility of producing them by chemical agencies is still *sub judice*. The majority of mutant genes in animals appear to be lethal when homozygous A proportion of these, including many so-called dominants, produce visible effects in the heterozygous condition.

In the normal type of sex determination one sex has two similar X-chromosomes, while the other has a single X, or more usually an X and a dissimilar Y. Besides genes carried by the X, the work of the last twenty-five years has disclosed others carried by the Y only (Schofield, Castle, Winge, Stern, etc) or by both X and Y (Schmidt, Aida, Winge, de Zulueta, Philip, etc.) Genetical anomalies of sex linkage occurs in females with an added Y-chromosome (Bridges), with attached X-chromosomes (L. V. Morgan), translocations of sex-linked genes to other chromosomes, and so on Bridges, by studying triploid *Drosophila*, showed that sex is determined not by the number of X-chromosomes but by the balance between them and the autosomes Thus animals with three sets of autosomes are females if they have three X-chromosomes, and intersexes if they have two Goldschmidt showed that in *Lymantria* the X-chromosomes contain genes making for maleness, the cytoplasm and perhaps other constituents making for femaleness By crossing geographical races of different sex potency he was able to produce intersexes or complete sex reversal In *Lebistes*, Winge has been able to shift the sex-determining mechanism to a different pair of chromosomes, producing XX- or YY-males instead of the normal XY

In Hymenoptera and some other groups the male is haploid Here Whiting and others have shown that all genes behave like the sex-linked (X-linked) genes in man But in *Habrobracon* at least, Whiting has proved that there is a further complication, the female being XY, the male X or Y, while X eggs are normally only fertilised by Y sperm, and conversely Thus genes in the X- and Y-chromosomes show a fourth type of sex-linkage

Finally, the Thallophyta have shown an astonishing variety of sexuality V Hartmann has found that in some flagellates sex is purely relative, a given type of gamete functioning as male with a less male partner, and conversely, while Kniep found two complementary sex pairs AB and ab, Ab and aB, in certain fungi, determined by two pairs of allelomorphic genes Still more complicated cases exist, and it is very difficult to draw the line between sexes on one hand, and exogamous groups of self-sterile hermaphrodite plants, which may be determined as in fungi (Correns) or by series of multiple allelomorphs (East and Mangelsdorf, Lehmann and Filzer, Sirks, Brieger, Crane, etc)

Much work has been done on individuals composed of two or more genetically different types of tissue, including mosaics, gynandromorphs, and plant chimæras They may arise from grafting, double fertilisation, loss of a chromosome, mutation and so on Among the most notable work is that of Morgan and Bridges on *Drosophila*, that of Jörgensen and Crane on *Solanum* and that of Imai on variegated plants

Besides inheritance due to genes, extranuclear inheritance undoubtedly exists The earlier work of Correns on the inheritance of abnormal plastid type has been extended, and other characters transmitted only by the seed parent have been recorded in plants Little finds that the tendency to spontaneous cancer is largely inherited from the mother. However, Michaelis showed that in one such case the cytoplasmic influence gradually disappeared in the course of ten generations,

whereas genes in the nucleus show no such tendency Jollos and Goldschmidt studied *Dauermodifikationen* in *Drosophila* and other animals These are changes of colour and shape produced by heat, and inherited from the mother only. Unlike mutant genes, they gradually disappear. A good many supposed cases of Lamarckian inheritance of acquired characters have been investigated Many have been disproved, and none has been conclusively proved However, the work of McDougall on rats and Sladden on *Carausius*, which suggest inheritance of acquired habits, are still under investigation

Apart from these rather aberrant cases, there is increasingly strong reason to think that all heritable variation is due to genes The evidence is particularly strong in *Drosophila* and *Zea Mays*, where characters determined by genes in several different chromosomes can readily be investigated by linkage tests Fisher showed that the data of the biometric school on inheritance of human stature were consistent with the view that stature is determined by a number of genes, and the work of Punnett and his colleagues on inheritance of weight in poultry and rabbits confirms this view

Human genetics has consisted largely of the accumulation of pedigrees Very many genes are known Thus Cockayne listed more than a hundred affecting the skin, hair or teeth In addition to abnormalities, the antigens of the blood cells were shown by Landsteiner, Bernstein, Schiff and others to exhibit Mendelian inheritance. In the economic field, sex-linkage has been applied by Punnett, Pease and Crew to determine the sex of young birds on hatching, and genetic principles are used to eliminate recessive lethals in cattle and horses, and to produce new varieties of various plants. But the main economic effect has been from the gradual permeation of genetical principles among practical breeders, which has shown itself for example in the grading of bulls by their daughters' milk yield.

The physiological side of genetics was particularly developed by Goldschmidt, who showed that genes determine the form of the adult by affecting larval growth rates Kraffka, Huxley, Zeleny, Plunkett and others have investigated the same problem. On the chemical side, Onslow, Garrod, Scott-Moncrieff, Brink and others have shown that in many cases a gene is responsible for some particular chemical process such as oxidation or methylation. The mechanism of segregation is itself controlled by genes (Beadle, Gowen, Frost, etc.), so that a change in one gene may affect the distribution of all the others

On the other hand, little is known of the nature of the gene. An analysis of multiple allelomorphism shows that different modifications of the same gene perform the same processes at different rates; however, in many cases it is certain that the genes do not consist of a number of like parts. At present the most hopeful line of attack on the fundamental problem of heredity, "How does one gene produce two like itself?", is to be found in the study of mutation, either natural, as in the work of Demerec and Andersson-Kottö, or provoked by X-rays. Andersson-Kotto's work suggests the possibility of distinguishing between a mother and daughter, or model and copy, in the products of gene 'division'

A possibly important clue to the nature of gene action lies in the fact that, whereas most characters, for example, presence of an organ or a pigment, depend on the interaction of many genes, the presence of an antigen has so far always been found to be due to a single gene Hence, except possibly in species crosses, no organism contains an antigen not found in either parent (Todd)

The cause of dominance has been much discussed Bateson and Punnett regarded it as due to the presence in the dominant gene of something absent in the recessive, Fisher believes it to be an adaptive phenomenon due to modifying genes Many workers take an intermediate point of view

Naturally polymorphic populations have been investigated, especially by Nabours, Winge and Fryer The genes concerned are often found to exhibit a surprising amount of linkage with one another Tschetwerikoff, Dubinin, Spooner and others have shown that an apparently homogeneous population may include many individuals heterozygous for recessive genes producing very marked variations

The species problem has been attacked from several sides Vavilov pointed out that homologous variations in similar species generally show similar inheritance, but Harland has shown that there are exceptions to this law, and characters may occasionally be determined by different genes in related species. Sturtevant established a thoroughgoing parallelism in the action and arrangement in the chromosomes of genes in two allied *Drosophila* species.

The differences between some species appear to be mainly due to genes. In the rodents this is so for colour, and Green has located a gene responsible for part of the colour difference between two mouse species in a particular chromosome. Other species differ as regards the number and structure of their chromosomes, and here hybrids, if they exist, are often sterile. In particular, Blakeslee and his colleagues have compared the arrangement of the chromatin in a number of species of *Datura* from this point of view, while Babcock has done the same for *Crepis* and J. Clausen for *Viola*. On the

whole, it may be said that while we are fairly clear as to the nature of the genetical differences between related species, and it has been possible to imitate them within a single species (for example, by producing races which differ morphologically and will not cross), we are only rarely able to say with any certainty how species have originated in Nature

The study of populations has developed a mathematical theory, due largely to Wright, Fisher, Bernstein, Haldane and Norton The most important problems studied have been the effects on a population of inbreeding, selection, and mutation, and the theory of estimation from samples These involve among other things non-linear integrals and finite difference equations, and complex theorems in inverse probability Their general result may be said to favour a modified Darwinian theory of evolution

It must be emphasised that the main bulk of genetical research has been done by authors not named in this summary, and even where no new principles have been discovered, their work has shown that the general laws laid down by Mendel have as wide a validity for genetics as have Dalton's for chemistry

Nuclear Structure and Chromosomes

By PROF R RUGGLES GATES, F R S , Professor of Botany, University of London

THE quarter-century of the King's reign has seen many striking advances in cytology, and particularly in our knowledge of the structure of the nucleus and its chromosomes During the decade ending in 1910, the general theory of 'individuality' of the chromosomes had been established by the work of Boveri and others, the sex chromosomes had been discovered by McClung, and their general relation to sex determined, chiefly by the work of Wilson and his school These remarkable beginnings definitely linked cytology with genetics and added strength to the view, already accepted in many quarters, that the chromosome reduction in meiosis furnished the physical basis for Mendelian segregation

An equally notable line of research begun before 1910 was in determining the cytological basis of the mutations discovered by de Vries in *Oenothera* This work laid the foundation for an analysis of mutations, so that by 1915 it was recognised that each mutation was in effect a cell change handed on by mitosis to every cell of the mutant. It was also recognised at this time that mutations could be classified into various types, which depended for their origin upon different kinds of chromosome change The process afterwards known as non-disjunction had been discovered in the pollen mother-cells of *Oenothera rubrinervis* in 1908, and by 1912 it was proved that the mutant *Oe. lata* must have arisen by such a process, as it possessed an extra chromosome. Many other *Oenothera* mutations are now known to have an extra chromosome, and the conception of parallel mutations was founded upon the occurrence of *lata* and other mutations in different species.

These chromosomal mutations were regarded by many as convincing evidence of the chromosome theory of heredity. Recently (unpublished), trisomic $(2n + 1)$ mutations have been found occurring on a large scale in a wild species of *Oenothera* Similar conditions have been observed by Huskins (1927) in fatuoid oats and speltoid wheats, plants with 40, 41, 42, 43 and 44 chromosomes being found where 42 is the normal number, but the exact relation between fatuoidy and the extra chromosome is still undecided Blakeslee and his colleagues have recognised the twelve trisomic mutants to be expected in *Datura*, which has twelve pairs of chromosomes, as well as a series of secondary forms derived from exchange of segments in the primary trisomics

In 1907-9 the mutant *Oenothera gigas* was recognised as a cell giant which had doubled its chromosomes This was the beginning of the enormous modern field of polyploidy, or plants with chromosome multiples The mutant *semi-gigas* was found to have 21 chromosomes (triploid) by Stomps and Lutz independently in 1912 Triploidy was discovered in *Drosophila* in 1921 and in *Datura* in the following year While rare in animals, polyploidy is so widespread in flowering plants that a genus which does not show at least one case of it may almost be regarded as exceptional Nearly all our cultivated plants, such as wheat, oats, sugarcane, cotton, apples, cherries, tomatoes, potatoes and pineapples, are now known to have varieties or species which possess different multiples of a particular basic number Among wild species of roses, chrysanthemums, maples, horse-chestnuts, docks, violets, primroses, clovers, ragweeds, strawberries and many others, similar conditions prevail, so that the evolution of many plant genera has clearly been accompanied by the development of higher chromosome multiples from an original basic number, such as $b = 7$, 9, 13 or 17, for the genus Where $2b$ is the ordinary (diploid) condition, some species may have $4b$, $5b$, $6b$, $10b$, or occasionally even higher multiples.

Thus in the genus *Potentilla*, where $b = 7$, species with $2b$, $4b$, $8b$, $10b$, $12b$, $14b$ and $16b$ are known.

In the cottons, where $b = 13$, it was found (Denham, 1924) that the Old World species had $2b$ chromosomes while the cultivated American cottons have $4b$ More recently, several wild species in Lower California and the Galapagos have been found to be diploid When and how the chromosome doubling in the cultivated cottons took place is at present unknown

Wild species with an odd number of chromosome multiples reproduce apomictically, as, for example, the pentaploid roses, the tiger lily, which is triploid, and the triploid day lilies In large genera there may be several basic numbers, as in *Primula*, where different sections or subsections of the genus have 9, 10, 11 and 12 respectively as basic numbers Less is known as to how one basic number changes into another, but there is evidence that end-to-end fusion of certain chromosomes, fragmentation and non-disjunction as well as other changes have been at work In *Drosophila* it seems clear that six pairs of chromosomes, which some species (for example, *D virilis*) still have, was the original number, this number being diminished to five pairs in *D obscura* and four in *D melanogaster* and other species by fusion to form the long pairs *D Willistoni* has only three pairs, the small pair having disappeared Changes in the relative lengths of chromosomes have also been taking place in various genera

These discoveries regarding polyploidy are fundamental for an understanding of phylogeny, the results of crossing, and various other fields of genetics

In 1922 Blakeslee discovered haploidy in *Datura*, that is, that an egg cell may develop parthenogenetically to produce a plant having a single set of chromosomes in its nuclei Such a plant is usually much dwarfed and almost completely sterile, since the chromosomes have no mates and are irregularly distributed in meiosis, but it is significant that it has the morphology of the sporophyte Haploids have since been discovered in such plants as *Crepis*, tobacco, wheat, tomatoes, *Oenothera*, and in rice, where Japanese investigators have found them to occur with exceptional frequency

Finally may be mentioned the remarkable cases of amphidiploidy, in which a sterile interspecific hybrid doubles its chromosomes and so becomes in effect a new fertile species with a higher chromosome number The early case of *Primula kewensis* is now known to be of this character (Pellew and Newton, 1929). *Nicotiana digluta* was produced in this way by Goodspeed and Clausen in 1925 and *Digitalis mertonensis* at Merton in 1928. There is evidence that such cultivated plants as tobacco and the loganberry have originated by similar processes Remarkable in this connexion is the history of *Dahlia variabilis*, which is native to Mexico and shows a double series of colours as well as the well-known striking morphological variations It has been shown to be an amphidiploid, the two colour series being contributed by different species (Lawrence, 1929) It may well have originated under cultivation in Aztec gardens

Even more striking has been the creation of the 'new genus' *Raphanobrassica* by crosses between the cabbage and the radish, each with $n = 9$ chromosomes (Karpechenko, 1924), and *Aegilotrichum* by crosses between *Aegilops* and wheats (Tschermak and Bleier, 1926) Amphidiploids between wheat and rye have also been obtained by Tumyakov at the Saratov station on the Volga, and recently by Lebedeff in the Ukraine, who claims that they reproduce apomictically If so, this is a further similarity to some of our wild polyploid species in such genera as *Hieracium* and *Antennaria* The fact that the tetraploid hemp nettle, *Galeopsis Tetrahit*, a well-known Linnean species in the British flora, has been synthesised by crossing two related diploid species, and that the rice grass, *Spartina Townshendii*, which spreads so rapidly in coastal waters, was found to be an amphidiploid hybrid between a British and an introduced American species, shows the importance of polyploidy in phylogeny and in connexion with taxonomic studies The experimental amphidiploids are new species in every sense of the word, for not only do they breed true in the main, like other species, but they are partially sterile with the species which produced them The two processes of doubling the chromosome sets and then differentiating them through gene mutations can be traced in many plant genera

To return to 1910 Morgan published his first mutation in *Drosophila*—red eyes to white—in that year, and in the following year found nine wing mutations and five mutations in eye colour In 1912 the study of sex-linkage in *Drosophila* began, crossing-over soon came to be studied on an unprecedented scale and in this way more than five hundred mutations have been assigned their relative positions in the four pairs of chromosomes. By 1926 it was possible for Morgan to announce his law that the number of linkage groups corresponds with the number of chromosome pairs This was confirmed by Punnett for *Lathyrus* in 1927; and in maize, where each of the ten pairs of chromosomes can be identified by its appearance, a map of the genes in each chromosome has been constructed by crossing-over experiments, chiefly by the Cornell school In 1916, Bridges used cases of non-disjunction of the X-chromosomes in *Drosophila* to prove that sex-linked genes were

borne in the *X*. Later, he also found individuals with a third member of the tiny fourth chromosome, as well as others having but one member of this pair

Morgan's theory of crossing-over was founded upon Janssen's observations (1909) of chiasmata in meiosis, but exactly how chiasmata are formed and how they are related to crossing-over is still a matter of controversy on which many observations are being made and various views are held

In 1922, L. V Morgan found a strain of *Drosophila* in which the two *X*-chromosomes of the female had become permanently attached end-to-end Before the condition was observed cytologically it had been predicted on the basis of the peculiar breeding results with this strain The condition has since appeared independently in other strains.

Arrangement of the chromosomes of *Oenothera* in a chain at diakinesis was discovered in 1908, and in 1922 Cleland found that the number connected into a ring was characteristic of certain species This condition, which is now known as catenation, is recognised as fundamental to the genetics of *Oenothera*, and the catenation in many species, hybrids and mutations, has been determined It accounts for the usual absence or infrequent occurrence of ordinary Mendelian segregation, the occurrence of 'complexes' of characters, the twin hybrids of de Vries and the fact that heterozygous species breed true In order to account for all these phenomena it is necessary to assume, not only that the chromosomes occupy fixed positions in the ring, but also that they have a fixed orientation This has recently been shown experimentally to be the case The 14 chromosomes of *Oenothera* may be all in a ring or in seven pairs or with various arrangements of smaller rings The fifteen possible groupings (a few unpublished) have now all been observed in different forms of *Oenothera*

Chromosome catenation has since been discovered in a number of other plant genera, including *Datura*, *Aucuba*, *Rhœo* and *Pisum* It can be produced by crossing two Oenotheras each with seven free pairs, and also by crossing certain strains of *Datura* or *Pisum*. Of special interest is the cross between a Tibetan and a European variety of *Pisum* (Pellew and Sansome, 1931) in which a ring of four chromosomes arises. Catenation has also recently been produced in *Oenothera* by exposing the pollen to X-rays The theory of segmental interchange was proposed by Belling and Blakeslee (1926) to account for the chromosome linkage arising in certain *Datura* crosses, and has since been shown to be widely applicable to *Oenothera* and all other cases in which ring formation takes place as a result of crossing.

In 1927 Muller announced that the mutation rate in *Drosophila* could be increased a hundredfold by subjecting the germ cells to X-rays The exact nature of the effect on the chromosomes is still unknown, but in addition to gene mutations, many of which are lethal, chromosome fragmentations, deletions and segmental translocations are produced by this means It has been applied to various plants, notably *Nicotiana*, barley, *Antirrhinum* and recently *Oenothera* There are now many lines of evidence that translocation of chromosome segments can take place in Nature, and it has been shown, for example, by comparing the seriation of the genes in *Drosophila melanogaster* with that in *D simulans*, that a segment of chromosome III in one of these species has been inverted.

Phylogenetic significance also attaches to the secondary pairing of chromosome bivalents in meiosis This was first observed by the Marchals (1911) in mosses in which the chromosome number had been doubled experimentally Hagerup (1927) noted it in a hermaphrodite tetraploid species evidently derived from *Empetrum nigrum* Darlington (1928) used it in interpreting the history of the polyploid cherries Secondary pairing appears to be due to a residual attraction, and indicates that the chromosome bivalents which show it are themselves more distantly homologous In other words, it is an indication of polyploidy or similar processes in the more remote ancestry, and throws light on how chromosome numbers have changed from genus to genus The Pomoideæ, a group of Rosaceous genera, have 17 chromosomes They show secondary pairing and other multivalent associations (Darlington and Moffatt, 1930) which indicate how this number has been derived from an earlier 7, which is characteristic of many genera in the family, such as *Rosa* itself Secondary pairing has been observed also in *Pyrus*, *Dahlia*, *Brassica*, *Gossypium* and many other cases, where it helps to throw light on nuclear phylogeny (Lawrence, 1931)

Important advances have also taken place in regard to chromosome structure, although in this fascinating field many points are still unsettled Most investigators appear to be now agreed that the chromosomes are double in anaphase as well as prophase, from which it follows that the split occurs about the time of metaphase and that the chromosome is a double structure throughout the mitotic cycle. The chromonema theory, according to which the essential part of the chromosome is a thread of uniform thickness, dates from Vejdovsky, 1912 The chromomere theory, of granules aligned like beads on a string, is much older. Both views have strong supporters at the present time and it does not yet appear how their differences will be

resolved Wenrich (1916) found that in grasshoppers particular chromomeres could be identified by their size and position on the chromosome Belling (1931) identified the chromomeres with the genes, and attempts at counting them in various plants have given values ranging roughly from 1000 to 2500 The chromosome threads become spiral in various stages of mitosis, and Kuwada has found indications of a spiral within the spiral Others find the spiral chromonema splitting lengthwise in prometaphase

In what may be called the external morphology of the chromosomes more marked progress has been made In 1912, S Navashin discovered that certain chromosomes in *Galtonia* have a tiny more or less globular satellite attached to one end by a thread One or more pairs of satellited chromosomes have since been observed in many plants and animals

The spindle fibre attachment constriction is now a well-recognised feature of all plant chromosomes, and 'kinetic bodies', 'knobs', 'heads', additional constrictions, vesicles and their special features have been observed Levitsky, M Navashin and others of the Russian school have been active in comparing the karyotypes of various plant groups

The nature of the nucleolus has long been a mystery, but light has recently been thrown on this problem Wenrich (1916) noted in the meiotic nuclei of a grasshopper that the nucleolus bore a constant relation to a particular pair of chromosomes Later a definite 'nucleolar body' was discovered as a darker staining area of the nucleolus in pollen mother cells of *Lathyrus* (Latter, 1926), and it was shown that a loop of the chromosome thread was constantly attached to it The same condition has since been found in *Lathræa*, *Oenothera*, *Malva* and rice, and frequently two such bodies rather than one are attached to the nucleolus S Navashin had observed a pair of satellites attached to the nucleolus, and in studies of maize, McClintock (1931) has shown that the satellited pair of chromosomes is concerned in producing the nucleolus in teleophase at a particular locus When these chromosomes are widely separated, two nucleoli will be produced. Heitz (1931) has observed similar conditions in *Vicia* and other plants as well as in insects (1933), while Dearing (1934) shows in the amphibian *Amblystoma* the same relation between a satellited pair of chromosomes and the (usually two) nucleoli present Thus it appears to be the function of a particular locus of one pair of chromosomes to produce the nucleolus, but this is not the whole story In this, as in other fields of nuclear study, the results in animals and plants have been remarkably synchronised

Lack of space prevents more than mention of the important method of micro-dissection, by which living cells can be dissected with glass needles under an immersion lens Introduced by Kite and Chambers in 1912, it has led to many interesting observations of the physical condition of various cell constituents, including the chromosomes

Finally, we may refer to the investigations of the chromosome structure in the salivary glands of insects. These giant chromosomes have long been known to show a banded structure, but its significance has only been brought out by the recent observations of Painter, Bridges, Koltzoff and others The discs differ markedly in details of structure, but they are definitely spaced at varying intervals along the chromosomes, and from the evidence of their pairing and genetic behaviour it is clear that they must be identified in some way with the genes Certain of the bands have been shown to vary according to the genetic make-up of the animal Bridges has just published (*J. Hered*, 26, No 2) maps of the four chromosomes (significantly separated into six) in the salivary glands of *Drosophila melanogaster*, identifying each band and also pointing out many other structural features or landmarks at various loci of the chromosomes These chromosomes total about 1180 μ, or 150 times the length of the meiotic chromosomes The bands, which probably represent loci, number 2650, the little fourth chromosome having 34 This begins a new era in chromosome study

Chemistry of the Anthocyanins

By PROF R. ROBINSON, F R S, Waynflete Professor of Chemistry, University of Oxford

THE classical paper of Willstätter and Everest (1913), on the isolation of the pigment of blue cornflowers, heralded a dramatic transformation of the state of our knowledge of the blue and red colouring matters of flowers and blossoms, and the present position is that we not only know the molecular structure of the more important and widespread anthocyanins, but also that many of them have been made artificially in the laboratory. With the simultaneous growth of precise information about chlorophyll, the carotenoids, the polysaccharides and the terpenes, one may say that all the more obvious challenges of vegetative Nature to the organic chemist have been taken up, and taken up successfully. Deep mysteries there are still, it is true, but one must probe

beneath the surface in order to find them Willstätter owed his triumph largely to recognition of the fact that the anthocyanins, although non-nitrogenous, form salts with strong acids, and these salts can be purified by means of the technique appropriate to many ammonium salts, that is, solution in a hydroxylic solvent and precipitation with a non-hydroxylic solvent

An early observation records the unconscious use of formic acid for the extraction of an anthocyanin J Wray (1670) wrote "Bare an ant-hill with a stick and then cast the [chicory] flowers upon it, and you shall see the ants creep very thick over them Now as they creep, they let fall a drop of liquor from them, and where that chanceth to light, there you shall have in a moment a large red stain" This was followed up and red extracts of blue chicory flowers were made with acidic solutions

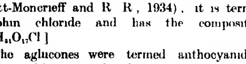
Willstätter and his colleagues extracted the anthocyanin salts by means of methyl alcoholic hydrogen chloride, acetic acid or other similar solvents, and precipitated a crude, often syrupy, product with ether The process was usually repeated, perhaps with variation of solvent, and until the anthocyanin could be caused to separate from aqueous or alcoholic solution as a chloride or picrate Purification was then possible by crystallisation, or a series of separations leading to eventual crystallisation The different examples offered very divergent degrees of difficulty and indeed, in some cases, the skill of the florist in the breeding of deeply-coloured varieties has been such that the dried petals can almost be regarded as crude anthocyanin

The blue cornflower and the red poppy represent the more difficult type, whereas the colouring matter is readily isolated from special deep red varieties of dahlias and chrysanthemums and from certain garden violas The dried petals of the blue-black viola (*Viola tricolor*) employed by Willstätter and Weil (1916) for the isolation of violanin contained no less than 24 per cent of this pigment

Willstatter was fortunate in the selection of material because among the first flowers studied were to be found representatives of the three main types in the group. From the cornflower, the rose and the dahlia he obtained cyanin chloride, $C_{27}H_{31}O_{16}Cl$, which splits up on hydrolysis into *cyanidin* chloride, $C_{15}H_{11}O_6Cl$, and two molecules of glucose; from the scarlet pelargonium he isolated pelargonin chloride, $C_{27}H_{31}O_{15}Cl$, which similarly yields on hydrolysis two molecules of glucose and *pelargonidin* chloride, $C_{15}H_{11}O_5Cl$, whilst the wild purple larkspur afforded delphinin chloride, $C_{41}H_{38}O_{21}Cl$, which gives, on hydrolysis, *delphinidin* chloride, $C_{15}H_{11}O_7Cl$, along with two molecules of glucose and two molecules of *p*-hydroxybenzoic acid [Anthocyanins containing acyl groups, often *p*-coumaric acid (Karrer), are widely distributed and are termed *complex anthocyanins* The true analogue of pelargonin chloride and cyanin chloride in the delphinidin series has recently been isolated from *Salvia patens* (Reynolds, Scott-Moncrieff and R R, 1934), it is termed delphin chloride and has the composition $C_{27}H_{31}O_{17}Cl$]

The aglucones were termed anthocyanidins, and in addition to the three already mentioned only certain of their methyl ethers have been encountered The two or three exceptional cases serve merely to establish the rule that all the anthocyanins are derivatives of the three basic types Further work showed that the aglucones may be combined with one molecule of glucose or of galactose, or with a rhamnoglucose or aldo-pentoglucose, and that isomeric diglucosides exist Thus mecocyanin chloride (from *Papaver rhoeas*) is quite different from cyanin chloride, but like it has the composition $C_{27}H_{31}O_{16}Cl$, and it also furnishes cyanidin chloride and two molecules of glucose on hydrolysis

The probable nature of the difference between pelargonidin, cyanidin and delphinidin is clearly indicated by the results of fusion with potash All three give phloroglucinol (I) as one of the products,



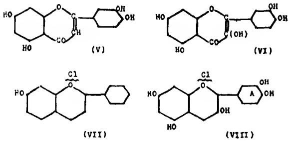
(I) (II) (III) (IV)

but pelargonidin was in addition degraded to *p*-hydroxybenzoic acid (II), cyanidin to protocatechuic acid (III) and delphinidin to gallic acid (IV)

Taking into consideration the results of precedent investigations on natural flavones (luteolin, V) and flavonols (quercetin, VI) with which the names of Kostanecki, A G Perkin and Herzig are chiefly associated, and also the accumulated knowledge of the properties of flavylium salts (such as VII) (Collie, Werner, Bulow, Decker, W H. Perkin and R R), it was apparent that the facts pointed to the formula VIII for cyanidin chloride The formulæ for the other anthocyanidins would be derived by modifications of the group A in VIII to conform with the results of potash fusion as mentioned above

This surmise was quickly justified by the discovery that flavones and flavonols could be reduced by metals in acid solution with the

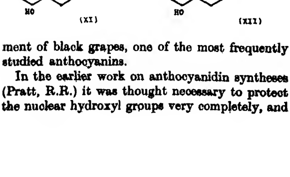
formation of oxonium salts having the reactions of anthocyanidins (Everest, Willstätter) In particular, Willstätter and Mallison showed that quercetin gives a small yield (0 6 gm. from 30 gm) of pure cyanidin chloride when it is reduced in



(V) (VI) (VII) (VIII)

aqueous methyl alcoholic hydrochloric acid by means of magnesium (VI ⟶ VIII) This was followed up by a more formal synthesis of pelargonidin (Willstatter and Zechmeister), whilst the present writer and his collaborators have synthesised all the anthocyanidins, including the methyl ethers, by convenient and generally applicable methods

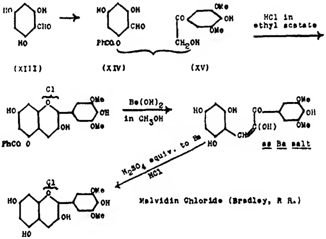
The naturally occurring methyl ethers of the anthocyanidins are peonidin chloride (IX), the aglucone of peonin, a diglucoside, and oxycoccicyanin, a monoglucoside, petunidin chloride (X), the aglucone of petunin chloride, a diglucoside, malvidin chloride (XI), the aglucone of a monoglucoside, a monogalactoside, a diglucoside, and of complex anthocyanins, hirsutidin chloride (XII), found only as the aglucone of hirsutin chloride, a diglucoside of *Primula hirsuta* (Karrer) Of these, malvidin, also called syringidin and œnidin, is of such frequent occurrence that it almost deserves recognition as a fourth fundamental type Its monoglucoside is œnin, the pigment of black grapes, one of the most frequently studied anthocyanins.



(IX) (X) (XI) (XII)

In the earlier work on anthocyanidin syntheses (Pratt, R.R.) it was thought necessary to protect the nuclear hydroxyl groups very completely, and the products were finally demethylated by means of hot hydriodic acid Such a process could clearly not be applicable to the methyl ethers (IX–XII), and a technique has been gradually evolved that allows of the minimum of protection, and that by means of acyl groups only The scheme below illustrates the stages of the synthesis of malvidin chloride by the best-known method

Phloroglucinaldehyde (XIII) may be synthesised from carbon *via* five isolated intermediate stages, namely, acetylene, benzene, nitrobenzene, trinitrobenzene, phloroglucinol; hydrocyanic acid is also used and may be obtained from carbon in two stages The intermediate XV may be synthesised from carbon in thirteen isolated stages, namely, acetylene, benzene, benzoic acid (better in one more stage), disulphobenzoic acid, 3 5-dihydroxybenzoic acid, bromodihydroxybenzoic acid, gallic acid, trime-



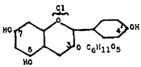
(XIII) (XIV) (XV)

thoxybenzoic acid, syringic acid, acetylsyringic acid, acetylsyringoyl chloride, diazodimethoxyacetoxyacetophenone, ω-4-diacetoxy-3 · 5-dimethoxy-acetophenone, two carbon atoms are introduced by way of carbon monoxide, methyl alcohol, methyl sulphate, and one from carbon monoxide, methyl alcohol, methylamine, methylurea, nitrosomethylurea, diazomethane

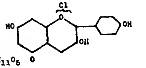
The monobenzoylphloroglucinaldehyde (XIV) has been found to be a particularly convenient first component in all syntheses of the above type, and its use (Robertson, R R.) facilitated the synthesis of the anthocyanins themselves. Hints in regard to the site of the sugar residues in the anthocyanins had been obtained from a study of their colour reactions and other properties (Willstätter, Karrer, R. R and their colleagues) in comparison with synthetic, analogous flavylium salts, but it is unnecessary, in this brief article, to recount the arguments, especially as none of them was conclusive. The case is one in which synthesis has

been applied not merely to the confirmation but also to the determination of structure

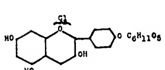
Nor is it necessary to mention the several stages of approach to the synthetic method, which is identical in principle with that already described It was a question of applying the art of the organic chemist to the preparation of the various glucosidated intermediates of types XIV and XV For example, by suitable modifications the four possible isomeric β-glucosides of pelargonidin were



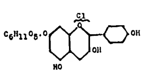
(XVI)



(XVII)



(XVIII)



(XIX)

synthesised (XVI, XVII, XVIII, XIX) (Robertson, Léon, Seshadri, R R); XVI was found to be identical with Willstatter's callistephin and XVII with his pelargonenin, not a natural anthocyanin but the first product of the hydrolysis of the diglucoside, pelargonin

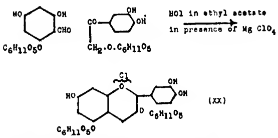
The natural monoglucosidic anthocyanins are all constituted like XVI The naturally occurring mono-glycosides synthesised are callistephin (from the aster or red carnation), chrysanthemin (cyanidin 3-glucoside from the chrysanthemum and other flowers), oxycoccicyanin (peonidin 3-glucoside from American cranberries), œnin (malvidin 3-glucoside from purple-black grapes), fragarin (pelargonidin 3-galactoside from strawberries), idæin (cyanidin 3-galactoside from European cranberries), primulin (malvidin 3-galactoside from *Primula sinensis*) The last-mentioned case is of interest because it illustrates the value of one of the methods used for the characterisation of anthocyanins. The monoglucosides are distributed between dilute hydrochloric acid and *iso*amyl alcohol, but the distribution number varies with the concentration By plotting the logarithms of the concentrations in the aqueous and alcoholic layers against each other, a straight line is obtained with a slope of 2; this indicates that double molecules exist in the water and single molecules in the *iso*amyl alcohol. The curves obtained in this way are much more reliable than single determinations of the distribution numbers because they afford evidence of homogeneity.

In connexion with work on the bilberry pigments, malvidin 3-galactoside was synthesised (Bell, R R), and its distribution properties were found to differ from those of œnin (malvidin 3-glucoside), so that a study of malvidin 3-glycosides containing unidentified sugar residues was feasible Cyclamin (from cyclamen, Karrer) was found to be identical with œnin, but primulin (from *P sinensis*), isolated by Miss R Scott-Moncrieff, tallied with the galactoside Closely related to the monoglycosides are the true biosides, and one example has been cleared up by synthesis Cyanidin 3-cellobioside, 3-maltoside, 3-lactoside and 3-gentiobioside were synthesised (Inubuse, Grove and R R) and the latter was found to be identical with Willstatter's mecocyanin The rhamnoglucosides have not yet been prepared in the laboratory but their reactions are closely similar to those of known 3-saccharides

There remain the diglucosidic anthocyanins *par excellence*—pelargonin, cyanin, malvin, etc At first regarded as biosides, these are now known to be di-monoglucosides, and the two sugar residues are attached to different hydroxyl groups of the anthocyanidin molecules

The suggestion that they are 3 5-diglucosides was first put forward in a letter to the Editor of NATURE (G M. R and R R) and it was quickly confirmed by synthesis The glucose rests must be introduced into both components Normally and preferably these were acetylated, and the product was submitted to hydrolysis by alkali and reconstituted by the action of hydrochloric acid

It is perhaps a matter of interest that cyanin chloride (XX) has been synthesised directly from unprotected components (Rosuggan, R R)

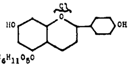


(XX)

The naturally occurring 3.5-diglucosides synthesised include pelargonin, cyanin, peonin, malvin and hirsutin (Todd and R R); the additional case of delphin has been mentioned already

The possession of pure synthetic specimens of the anthocyanins and anthocyanidins has made it possible to devise simple tests for the rapid recognition of the nature of the pigments in crude extracts of plant material, and a survey (G. M R and R. R) has been made of a wide variety of flowers and other parts of plants in respect of their

anthocyanin content In general, we are able to specify the anthocyanidin and the position of the sugar groups, but the latter cannot be identified (except for rhamnose and the aldopentoses) This survey has made the dominating position of pelargonidin, cyanidin, delphinidin and malvidin even more clear, but it has also disclosed the occurrence in Nature of certain widely distributed anthocyanins not yet isolated in substance As examples, the pelargonidin 3-bioside of the orange-red nasturtium and the pelargonidin 3-rhamnoglucoside of the scarlet gloxinia may be cited The orange-scarlet flowers of *Gesnera fulgens* were found to contain a new anthocyanin termed gesnerin, it is apigeninidin 5-glucoside (XXI) and has been synthesised (Todd, G M R and R R), it is the only known anthocyanin related to a flavone rather than to a flavonol, although carajurin (XXII), a crystalline constituent of a cosmetic pigment used by the natives of the Orinoco, is a colour-base of such a substance (Chapman, A. G Perkin and R R) Other special types of anthocyanins are the nitrogenous pigments of *Beta*, *Bougainvillæa*, *Amaranthus*, *Celosia*, etc, their nature has not been fully elucidated, also the bright yellow water-soluble colouring matters of *Papaver alpinum* and *P nudicaule*



(XXI)

(XXII)

Among the matters of more general interest connected with the anthocyanins are the causes of colour variations in flowers, considered both statically and dynamically, that is, the actual condition of the pigment on one hand and its relation to genetic factors on the other On the first aspect it may be noted that the pigments are indicators, the colours ranging from red oxonium salts to blue or violet salts of the colour-bases which are also acids Thus cyanin chloride has a beautiful bluish-red colour, cyanin-base is violet and the potassium salt of cyanin-base is blue Naturally, therefore, the colour of a flower is dependent on the pH of the cell-sap. But the range of pH is much smaller than experiments *in vitro* would suggest, and this is due to the combination of the anthocyanin colour-base with colloids tending to stabilise the anthocyanin anion at a pH which it could not survive in 'clean' solutions.

Another factor modifying the conclusions drawn from the indicator ranges observed in the laboratory is the presence of co-pigments in the flowers. These are organic substances, mainly flavonols and tannins, which have a blueing effect on the colour irrespective of the pH The magnitude of the effect is, however, dependent on the pH and at a certain value becomes maximum The phenomenon is the result of actual combination with the pigment and is accompanied by a marked change (diminution) of the distribution number

A very characteristic reaction of cyanidin, petunidin and delphinidin derivatives is the deep blue ferric reaction The presence of iron in the cell-sap might, therefore, be responsible for blue colours Recent analysis of blue and red hydrangea flowers by Manly have been interpreted in this sense, and although this popular problem cannot be said to have been completely solved, the presence of iron and other metals must be reckoned with in considering the factors responsible for flower colours

On the genetical aspect little need be said here, the subject deserves a separate treatment Obviously the anthocyanin approach to the study of heredity represents one of the most promising lines of investigation, and it will be greatly facilitated by the chemical advances here briefly summarised Miss Scott-Moncrieff and her colleagues have recently completed an investigation of the dahlias (private communication) which goes far to show that the pelargonin, cyanin and flavone or flavonols occurring in these flowers are biogenetically complementary and are phytosynthesised from a limited supply of protoflavan material The full details will be studied with interest, and this type of investigation is pregnant with possibilities in connexion with the elucidation of the mechanism of anthocyanin synthesis in the plant

I consider that the identification of the anthocyanin-chromogen with the flavones was an unfortunate obsession of the plant physiologists, and that in a different form the oxidase hypothesis of Keeble and Armstrong will be revived.

The leuco-anthocyanins of Laborde, Rosenheim and others will probably be found to be much nearer the mark These substances are even more widely distributed than the anthocyanins (G. M. R and R. R.), and their constitution may be foreshadowed by an investigation of peltogynol recently carried out in these laboratories (G M. R and R R.). This is a constituent of certain woods known as 'purpleheart', and it is essentially a dihydrodesoxycyanidin condensed with formaldehyde. It is thought that the leuco-anthocyanins as a class may be of similar nature, the sensitive partly reduced flavylium nucleus being protected in a semi-acetal sugar-like structure.

Adsorption Concepts in Chemistry

By PROF ERIC K RIDEAL, F R S, Professor of Colloid Science in the University of Cambridge

NO better perspective of the development of our knowledge concerning adsorption at surfaces can be obtained than by contrasting the contents of one of the many monographs published on this subject in recent years with the considered views of Nernst, as expressed in the sixth edition of his famous textbook in theoretical chemistry, which appeared twenty-five years ago At that time the process of adsorption on surfaces was regarded essentially as due to the formation on the substrate of a dense atmosphere-like layer many molecules thick Of this concept no vestige remains Whilst the fundamental qualitative expressions of the more modern views are essentially simpler and more direct than the old, yet the detailed processes are undoubtedly complex and still await complete elucidation

Two fundamental concepts introduced some twenty years ago, envisaged by the late Sir William Hardy, but most clearly presented and demonstrated by Irving Langmuir, have had the greatest influence in moulding our present views The two ideas that the forces acting in the process of adsorption are to be recognised as identical with those operative in ordinary chemical processes, and that in molecules, especially in large organic molecules, certain portions are more reactive than others, form the basis of the modern concept of the orientated monolayer as the model of the adsorbed phase

The reality of the existence of adsorbed materials in the form of orientated monolayers both on solid and liquid surfaces has now been demonstrated by chemical, optical, electrical and thermal methods More detailed examination has revealed the fact that on liquid surfaces the material in the adsorbed monolayer can, like material in three dimensions, exist in various physical states akin to three dimensional vapours, liquids and solids, and that these phases can be transformed into one another each with its own definite change in free energy of transformation.

Examination of such monolayers on liquid surfaces by means of the Langmuir trough, and by determination of the phase boundary potential, now provides us with some information supplementary to the examination by X-rays as to the configuration of complex molecules like the sterols or proteins. It is also possible to measure the rate of reactions proceedings in these films, for example, such processes as enzyme reactions, chemical reactions involving hydrolysis, oxidation or two dimensional polymerisation. These reactions proceeding in monolayers at fluid interfaces are of great interest, in that not only may they be the prototype of a number of important biological chemical reactions which occur *in vivo*, but they also permit us to alter at will by mere compression or expansion the rate of reaction proceeding in the film, visual evidence of the reality of the factor termed the steric factor in homogeneous reactions

A much greater variety of phenomena is met with when investigating adsorption at solid surfaces Two distinct types of adsorptive processes are generally recognised, in one the forces holding the molecule to the surface originate in the mutual polarisation of the molecules and are frequently termed physical or Van der Waals' forces In suitable circumstances an electronic switch occurs and a chemical reaction takes place between the adsorbed molecule and one or more molecules of the substrate, forming a chemi-adsorbed complex It is customary to consider chemical compounds as belonging to one or other of the extreme types, one where the stability of the compound is due chiefly to the operation of coulomb forces between ions and the other where a bond or a valency force in the form of a pair of electrons is shared between two atoms in a binary compound We may cite the adsorption of the rare gases on mica, of cæsium on tungsten and oxygen on tungsten as typical representatives of these three types of surface compounds existing in the adsorbed phase

Whilst the molecules in a distended adsorbed phase on a liquid substrate can move freely over the surface by diffusion, such is not the case on a solid surface, where the adsorbed molecules must migrate *per saltum*, a process termed activated diffusion Such activated diffusion is not always limited to the surface of the solid, for frequently the process of adsorption is complicated by penetration into the solid through fissures, along slip planes, into large molecular holes, as obtain in the zeolites, or actually into the lattice of the solid itself, and in some cases it is possible to trace the changes in the mode of gas flow inward from simple diffusion to activated diffusion as the fissures change in size and the temperature is varied. As we have noted, the elimination of forces other than Van der Waals' and chemical in adsorption phenomena, does not permit of the assumption of the existence of an atmosphere-like thick adsorption layer, yet thick layers can be built up under suitable conditions by the operation of these short-range forces alone ;

thus relatively thick layers of sodium can be deposited upon tungsten It is possible that these are not intrinsically stable and may actually aggregate into drops embedded in a monolayer, as occurs when a relatively thick film of oleic acid is deposited on the surface of water Evidence for the formation of a second layer on the top of a first has often been brought forward, and indeed this phenomenon may be of frequent occurrence, thus a layer of oxygen molecules may be held on to the top of a layer of oxygen chemi-adsorbed on to tungsten The second layer is of course 'held' less tightly than the first, in consequence the second layer may be but sparsely populated under conditions when the first is almost complete, and molecules in the second layer may be much more mobile than the atoms or ions in the first It is indeed due to the surface mobility of the oxygen in this second layer that a tungsten wire becomes coated so rapidly with a chemi-adsorbed layer in oxygen at low pressures The adsorbed oxygen in the second layer moves over the surface and drops into any vacant hole in the chemi-adsorbed layer beneath

More recently, evidence has been brought forward that when gases, or more generally, vapours, are adsorbed by the operation of Van der Waals' forces, the adsorbed layer may exist under suitable conditions in more than one state, thus it is possible to describe phase changes on solid surfaces as due to two dimensional liquefaction or solidification from a two dimensional vapour phase

Similar phenomena are met with in cases of chemi-adsorption, but here the lateral attractive and repulsive forces between the adsorbed ions or dipoles, and their variation with the changes in the density of population, are great enough both to make a thorough study of the conditions of equilibrium in these two dimensional chemical systems on solid substrates an extremely complicated problem and to render the interpretation of the experimental data difficult

Adsorption of gases by solids is not always an extremely rapid process but may, over suitable temperature ranges, proceed with measurable speeds From the influence of temperature on the rate of the process, energies of activation may be calculated In many cases this slow process, requiring a definite energy of activation, can be ascribed to the slowness of the process of conversion of the Van der Waals' adsorbed molecules into the chemi-adsorbed complex, and for this reason chemisorption is frequently termed activated adsorption, although in a number of cases the process of chemi-adsorption, like many elementary reactions, can proceed with a negligible energy of activation.

A closer analysis of the problem suggests that there are at least three distinct processes where energy barriers may be involved, that is, three different energies of activation may have to be distinguished These are first, the transition of the Van der Waals' adsorbed molecule to the chemi-adsorbed state, secondly, the transition of a molecule or atom of the exterior of the solid to a place just inside the solid, and thirdly, the migration of this molecule farther into the interior

In many cases where the process of adsorption is proceeding slowly, it is a matter of some difficulty to find out which of these three energy barriers is actually responsible for controlling the speed of the reaction actually being measured

It seems certain that in many cases, where diatomic gases such as hydrogen, oxygen or nitrogen undergo the process of chemi-adsorption at metallic surfaces, a reaction occurs which is the preliminary stage in a number of heterogeneous catalytic reactions, some of these being of great industrial importance The resulting chemi-adsorbed complex involves only one atom of the gas undergoing chemi-adsorption Thus chemi-adsorption involves a process of dissociation of the molecule The application of the principles of the wave mechanics to the theoretical aspects of this problem suggests that the energies of activation should vary with the spacing or distance apart of the atoms forming the substrate Whilst the experimental evidence so far produced may be said to support this view, it has not yet been tested in a manner sufficiently rigorous to affirm the correctness of this important theoretical conclusion

Twenty-five years ago, no distinct ideas as to the mechanism of catalytic reactions at solid surfaces could be said to have been formulated The chemical view, which postulated the formation of intermediate compounds, could be found side by side with what might be termed a physical view, where it was supposed that the molecules in the condensed atmosphere not only collided more frequently but also the forces opposing reaction were in some mysterious way reduced to smaller magnitudes At the present time, it may be said that the chemical view has been fully substantiated, the catalyst provides by chemi-adsorption an alternative chemical path. Surface hydrides, oxides, nitrides, and more complex compounds—for example, such as are formed by chemi-adsorption of olefines on carbon—are known, and their properties have been examined Much further work is required before the detailed kinetics of these processes can be said to be definitely established, but it is clear that during the last twenty-five years the crops from the field thrown open by Hardy and Langmuir have been good, and bumper harvests may be expected in the future.

Food Storage and Transport

By DR FRANKLIN KIDD, Superintendent of the Low Temperature Research Station, Cambridge

THE state of affairs to-day with regard to the transport and storage of foods is very different from what it was twenty-five years ago The bulk that is handled is very much larger and the variety is much greater, and transport and storage are conducted over longer times and distances

Putting aside canning and drying as methods of preservation, and considering fresh foodstuffs only, this development has been due to the application of refrigeration over a wider and wider field

The success that has attended this development is founded on the intelligent grasp that has been everywhere shown of the fact that the use of low temperature as such is in itself only the widest of general principles Each type of foodstuff, be it fresh fish, meat, fruit or vegetable, is an infinitely complex material and subtly varying according to its growth and development The last twenty-five years have seen a great extension of our knowledge of the laws governing the changes in these organisms in their living and post-mortem states. To-day, scientific attention is given not only to the question of temperature control and to the maintenance of low temperatures during storage, but also to every stage of the pre- and post-storage history, with the object of producing foodstuffs, after long storage and transport, indistinguishable in appearance, palatability, digestibility and physiological value from the original fresh material.

A single example may be interesting here in illustration. It must be generally known what a difficult fruit the William pear is to handle even when grown in one's own garden It seems almost incredible that thousands of tons of this choice fruit should be successfully shipped in bulk to Great Britain from South Africa, California and Australia. This success could not be achieved unless in the first place an elaborate scientific technique existed for the proper production of the fruit, free from all blemishes: if the exactly right time for gathering the fruit based on a variety of tests had not been chosen: if the fruit had not been wrapped and systematically packed in cases by methods which have been evolved and standardised as a result of a long process of experiment and observation: if the fruit had not been rapidly cooled in special pre-cooling stores in the country of origin, if afterwards it had not been carried, of necessity in bulk, but with the arrangements of stowage and refrigeration by forced air movement so adjusted as to maintain a uniformity of temperature throughout the hold to within 1° F: and if finally, the fruit had not been properly ripened at a controlled high temperature after arrival in Great Britain in the winter months Disasters occur even to-day through failure in one or other of the links in this chain

Chilled beef is another good case in point illustrating this type of development The degree to which the quality of imported chilled beef approximates to that of the best 'home-killed' depends not only on the maintenance of the low temperature, but also its maintenance to within 0 5° F during shipment upon the proper breeding, feeding, resting and watering of the cattle before slaughter and above everything upon the utmost care in the maintenance of hygienic conditions during the dressing of the meat Bacterial counts are now made at the time the beef is chilled, and from these the condition of the meat on arrival after transport can be almost precisely foretold

One line along which much progress has been made is in the definition of the optimum temperatures for storage, and this is so principally with regard to fruit, and with regard to frozen fish and meats As a general principle, all fruits and vegetables have what is termed a low temperature tolerance limit They cannot of course be frozen without damaging the essential organisation of the fresh product Even above the freezing point, however, they cannot be stored too long below their tolerance limit without suffering from some form of functional breakdown and disorganisation Many types of breakdown of this class have now been detected and described in various fruits, and in a large number of cases the optimum temperature of storage has been accurately determined

In the case of frozen fish and frozen meats, scientific analysis has brought to light the fact that changes affecting solubility of the proteins occur most rapidly between $-2°$ C and $-3°$ C, and it has become clear that the dry tasteless condition previously encountered in frozen fish and certain meats can be avoided and the fresh state almost completely preserved if, in freezing and thawing, the material is taken rapidly enough through a critical range of temperatures below the freezing point, and if during storage it is held at a temperature between $-20°$ C and $-30°$ C.

One of the results of this discovery has been to open up a new source of fish supply to Great Britain Large vessels equipped with rapid freezing equipment and large storage capacity are able

to spend months away from port on the west coast of Greenland fishing for halibut and cod. An even more recent development, still in the experimental stage, is the preservation of a proportion of the herring harvest by quick freezing and low-temperature storage for subsequent, out of season, kippering and other uses

So far we have dealt with what might be described as improvements in the technique of storage by the use of low temperature A revolutionary development which has taken place within the last twenty-five years, a development which is probably even now only in its infancy, is the regulation of the composition of the atmosphere as an additional or accessory means of controlling biological change

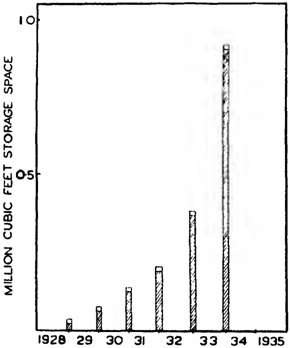


FIG 1 Increase in the capacity of gas-storage for apples in England, since 1929

The idea of using an inert gas for the better preservation of foodstuffs is, of course, an old one Modern developments in Great Britain may be said to have started with a series of papers which appeared in the *Proceedings of the Royal Society* in 1914–15, dealing with the respiration and germination of seeds as affected by oxygen concentration and carbon dioxide concentration. The Food Investigation Board, founded in 1917, took up from the beginning a systematic study of the question of applying the principle of atmosphere control to the storage and transport of food. In the first place, investigations were confined to fruit and fruit-rotting fungi The first commercial fruit store employing the combined control of the temperature, oxygen and carbon dioxide content of the air was installed in Kent in 1928, and since then the adoption of atmospheric control in fruit stores (gas-storage) has been rapid in Great Britain (Fig 1)

The effectiveness of the method is due to several facts The majority of English apples have a relatively high low-temperature tolerance limit, so that cold storage is not effective in the majority of cases for preservation beyond Christmas or January The rate of ripening is a function of the rate of respiration, and this can be retarded not only by lowering the temperature, but also by reducing the oxygen content of the air and by raising the carbon dioxide content There are, however, strict limits to which either operation can be safely carried without injuring the fruit. Carbon dioxide has a specific effect also in delaying the onset of what is known as the climacteric, a critical change of state which precedes the ripening changes of softening, and odour and flavour development

Twenty-five years ago, owing to the length of the voyage, the transport of chilled beef from Australia to Great Britain was an outstanding and apparently insoluble problem The limit for chilling was set by the activity of the micro-organisms—bacteria and moulds Could the rate of growth of these organisms be sufficiently reduced by any concentration of carbon dioxide which could safely be used without itself spoiling the appearance of the meat ? Laboratory experiments on the types of micro-organisms concerned, at the temperatures of chilled beef carriage, indicated that the life of the beef would be approximately doubled by employing an atmosphere containing 10 per cent carbon dioxide Simultaneous investigations showed that this concentration would be without appreciable effect upon changes in the fat leading to rancidity or those in the hæmoglobin leading to browning In 1933, the first shipment of gas-stored chilled beef was brought from New Zealand, and to-day there is an established trade in good quality chilled beef from the antipodes to Great Britain

The possibilities of atmosphere control are not limited to those dependent upon carbon dioxide and oxygen effects upon organisms—fruits, vegetables and micro-flora. As the result of the analysis of the critical part played by oxygen in the breakdown of unsaturated fatty acids and the production of certain types of rancidity, many types of dry foodstuffs containing fats are to-day packed in gas-tight containers from which oxygen is excluded. In the storage of bacon or cured pigs' flesh, this type of oxidative rancidity is usually the limiting factor, and storage in the chilled or frozen state does relatively little to retard these oxidative

changes in fat. They can, however, be eliminated by the use of atmospheres free from oxygen and containing a high carbon dioxide content, and by this method bacon can now be successfully stored for months as compared with weeks previously possible

Other improvements in the science and art of food storage and transport are dependent upon the use in special cases and for special purposes of atmospheres containing regulated traces of such gases as ozone, ethylene and ammonia Ozone removes undesirable substances from storage atmospheres, such as the 'volatiles' of ripening fruit, which in too high a concentration are harmful to the fruits themselves or 'taint' other products stored afterwards or simultaneously in the same space Ozone can also exercise a retarding effect on bacterial and mould growth Ethylene is used specifically to stimulate in fruits the climacteric change alluded to above, so that large quantities can be brought uniformly to the optimum stage of ripeness at the time desired Ammonia retards the germination of spores of decay organisms always unavoidably present to a greater or less extent on the surface of all kinds of fresh foodstuffs

In broad retrospect, the past twenty-five years appear as an era in which scientific and practical skill has achieved remarkable results in extending the scope of storage and transport as regards the prevention of wastage By a continuance of the same general methods—that is to say, progressive and intensive scientific analysis of the properties and behaviour of foodstuffs of all kinds and the close linking of practical application with new discovery —the next twenty-five years should see, I think, as great an advance in the quality of products as the past twenty-five years has witnessed in their quantity and variety.

Special Steels

By SIR ROBERT HADFIELD, Bt, F.R.S.

INTRODUCTION

THE author regards it as a privilege to be invited to review in these columns the general progress of special or alloy steels during the first twenty-five years of His Majesty's reign His pleasure in accepting this invitation is further increased by the fact that he had last year the honour of being one of the deputation from the Iron and Steel Institute to present His Majesty with the Bessemer Gold Medal, which he graciously accepted In doing so, His Majesty was following a precedent established by Queen Victoria and continued by King Edward VII, to whom in 1906 the author himself had the honour of presenting the Medal on behalf of the Iron and Steel Institute Thus for three generations the Royal Family has demonstrated its concern and interest for the welfare and progress of the iron and steel industry, upon which the prosperity of our country and its position in the world so largely depends.

Within the limits of space here available, it is not possible to give anything approaching a complete survey of advances in the vast field of special and alloy steels during the past quarter of a century The story is in fact one which begins much earlier and shows during this notable period of industrial activity the vigorous expansion of the era of alloy steels, which at its commencement had become well established but was then comparatively young In 1929 the world's output of steel, then at its maximum production, was 120 million tons, of which no less than about 6 million tons represented alloy steels

In reviewing progress in this period of twenty-five years it is necessary, therefore, to take account both of those newer alloy steels which it has seen initiated and also of the developments which have taken place in the use of those which had already found practical application

The author's discovery and invention of manganese steel in 1882, as expressed by so many well-known metallurgists, marked the dawn of the age of high alloy steels The extraordinary and valuable results then obtained led him to investigate in many other directions this hitherto practically unknown field, and later he was followed by numerous other investigators. To-day manganese steel, with modern improvements in manufacture, is used throughout the world in increasing quantities and for a greater variety of purposes than ever before In addition, there have been developed corrosion- and heat-resisting steels, high-speed tool steels, special steels for armaments and ordnance, special structural steels, high tenacity steels, and steels with remarkable magnetic properties, whether as regards low energy losses in electrical machinery and apparatus, specially high permeability at low magnetisations, or special suitability for permanent

magnets, as the case may be The arts of peace have been served in no less measure than the needs of national defence, and progress has been astonishingly rapid in all the branches of metallurgical knowledge concerned

MANGANESE STEEL

Much progress has been made, and many difficulties overcome, in the production and applications of manganese steel since the original specimens of this material were exhibited by the author at the reading of his first paper on this subject before the Institution of Civil Engineers in 1887, that is, almost exactly forty-eight years ago This alloy, now known throughout the world as the Hadfield manganese steel, consists of a non-magnetic alloy of iron with from 11 to 14 per cent of manganese and about 1 25 per cent carbon, and remains one of the most remarkable ferrous materials yet produced, whether from the point of view of practical application or scientific interest

Whilst the general progress of metallurgy has brought about improvement in the actual manufacture of the material, as also its heat treatment which plays such an essential part in the full development of its qualities, this important alloy, manganese steel, remains exactly the same as when originally invented in 1882

SILICON STEEL

The history of the development of this remarkable steel, invented by the writer in the latter portion of the nineteenth century, and how the early difficulties attending its introduction and production, including the best and most suitable proportions to be used of the element silicon, also heat treatment, were surmounted, are given very fully in his book "Metallurgy and its Influence on Modern Progress"

Since its first employment early in the present century, silicon steel has become of the highest importance in the electrical industry by its use in transformers, generators, motors and many other purposes. Without the use of silicon steel, the efficiency of electrical generation and transformation would be seriously lower than at present and many modern designs of electrical plant would be physically impossible owing to the increased energy losses

The hysteresis loss of this steel is initially about two thirds that of unalloyed iron, and actually decreases during a period of years in service. Its high electrical resistance, about six times that of iron, is also of great advantage in minimising losses due to eddy currents, while its maximum magnetic permeability is about 25 per cent higher than that of iron

CORROSION-RESISTING STEELS

The remarkable developments in corrosion-resisting steels, as also in heat-resisting steels to be referred to later, have taken place entirely within the past twenty-five years Several varieties of specialised types have been developed to meet different requirements There are many applications in chemical and other industries for materials combining resistance to corrosion with the mechanical properties of steel, that is, apart from the use of some of these special alloy steels for domestic and ornamental applications No single steel yet developed meets all possible requirements in this field, but many special steels have been perfected, and from these it is generally possible to choose one which is effective against any particular one or more of the many corrosive agencies encountered in industry

The simpler and original type of corrosion-resisting steel, usually termed 'stainless' steel, established by Brearley, containing 12–14 per cent of chromium and from about 0 05 per cent up to about 0 40 per cent of carbon, also still higher percentages such as 16–18 per cent of chromium, according to the purpose for which they are intended, have valuable mechanical properties, and are specially suitable for applications in which the corrosive action is of the ordinary kind, that is, due to air and water For chemical and other applications where a wider range of resistance to corrosion is required, the steels most generally used are of the nickel-chromium type, low in carbon and with from about 12–20 per cent of chromium and about 7–12 per cent of nickel, and in certain cases also small additions of elements such as tungsten, molybdenum and titanium, and other elements are being investigated such as columbium These materials are now available in castings, forgings, rolled sheets or bars, tubes and wire , also by machining, pressing, welding and other methods of assembly they can be fabricated into practically any form desired.

The development of non-rusting steel covers an exceedingly wide field and those specially interested in the history describing its origin and rise are recommended to refer to Chapter ix of the author's book "Faraday and his Metallurgical Researches" where the later development of alloy steels is dealt with.

Steels of this type are now used widely for

tanks, pans and other parts of chemical or other manufacturing equipment exposed to corrosive media too numerous to be mentioned individually, including many of the most commonly encountered acids and corrosive salts There is also large employment for these steels for decorative purposes where high polish is required For other applications, further and more special types of corrosion-resisting steels have been developed

One of these, for example, is useful in the sulphate house of coal and coke by-product recovery plants, owing to its resistance to dilute sulphuric acid Also it finds many applications in sugar refineries owing to its resistance to acid calcium phosphate and other chemicals employed , and it is specially valuable in food industries, being unaffected by the dilute solutions of phosphoric acid contained in chemical foods

In a very different field, the use of a corrosion-resisting special steel for the reinforcements of the masonry in the preservation of St Paul's Cathedral, London, suggests that such material will be employed to an increasing extent, ensuring the permanence of our historic buildings as necessity arises It will doubtless be a satisfaction to all concerned with the metallurgy of iron that the special steels so employed and supplied by three Sheffield firms are associated in such an important capacity with the safety of the cathedral in which the Royal Silver Jubilee Thanksgiving Service is to be held

In the construction of new buildings also, high tensile non-corrodible steel is being used, as in the case of certain structural members in the new library of the University of Cambridge

HEAT-RESISTING STEELS

Almost contemporary with the development of corrosion-resisting steels has been the recognition and utilisation of the merits of heat-resisting steels There are, in general, ferrous alloys with high nickel and chromium contents, variable in amount according to the properties required in the products In some cases, the iron content barely exceeds 50 per cent

The term 'heat-resisting', as applied to steels, implies resistance to oxidation and other forms of corrosion at high temperatures, while retaining a high degree of mechanical strength Materials fulfilling these conditions find many important applications, including the valves of internal combustion engines, rotors of gas turbines, mechanical parts of furnaces of all kinds, reaction vessels for coal-hydrogenation, and many other uses requiring mechanical reliability combined with freedom from oxidation and scaling. Developments in this field have been so numerous that it is impossible here to do more than indicate their variety and importance The following examples are, therefore, to be taken merely as representative and by no means exhaustive

Cast iron parts formerly used in mechanical stokers in the Canadian Pacific Steamship Company's vessels of the *Beaver* class, operating with air preheated to 310° F , were found to require replacement after every second round trip The parts exposed to the severest conditions, such as tuyères, grate plates, slicing bars and extension plates, were, therefore, made of heat-resisting steel, and the grates were then found to be in perfect condition after a year's continuous service Similar examples are provided in many other directions and, to take one at the other end of the scale, claw bars of heat-resisting steel in a certain type of domestic hot-water boiler are still in perfect condition after two years service, where new cast iron bars were formerly required every three or four months This is only one of many instances

The exhaust valves of internal combustion engines are, specially where high efficiency is aimed for, exposed to most difficult conditions as regards temperature, mechanical stress and liability to scaling and erosion Here again, special heat-resisting steels come to the rescue, and exhaust valves of such material have contributed to successive world speed records on land, water and in the air Similar conditions apply in the case of the rotors of exhaust gas turbines, in which applications equal success has been attained

For the vessels used in modern high-pressure high-temperature chemical processes, heat-resisting qualities must be combined with resistance to chemical action, and here again the conditions are being successfully met

The applications of these new alloy steels are, in fact, so numerous and important that they will probably have as important an influence on the progress of engineering and the economics of industry as that exerted by the earlier alloys, manganese steel and silicon steel, in their particular spheres

SPECIAL STEELS FOR ARMOUR AND ORDNANCE

Without ceasing for a moment to regret the waste and folly of war, it is impossible to ignore the important contributions to national defence resulting from the applications of special steels in armour, projectiles and other munitions during

the War Then, and, in fact, throughout the particular period under review, the rivalry between armour and projectile continued with steady improvement in each However, the reference made here to this subject can only be brief, though without doubt our nation must continue to supplement its work by continued efforts if national security is to be preserved

One of the most striking applications of alloy steel in the War, and one to which it is very appropriate to make present reference owing to its humanitarian aspect, was the use of manganese steel for the helmets of our soldiers and most of our allies Though commonly known as 'tin hats', these helmets were of the much sterner material known universally as the Hadfield manganese steel, and there can be no question that very large numbers of our brave soldiers owed their lives to the remarkable toughness and resistance to shrapnel fire of this extraordinary material with its non-magnetic qualities most useful in many cases

Special Steels for Other Purposes

At least a passing reference must also be made to high tenacity steels, large steel forgings of extraordinary weight and size, special steels for steam turbines and steam fittings, high-speed tool steels, in which great advances have been made, special magnetic steels and alloy steels for general engineering and constructional purposes Nor should it be forgotten that there have been important advances in the quality of carbon steels, which are strictly speaking alloy steels, for, of all the elements alloyed with iron, carbon is in many respects the most powerful and remarkable in its effects

Alloy steels possessing high breaking strengths up to 100 tons per sq in and above have been used by engineers for some time past, and there has been steady progress during recent years in the improvement of the quality of such high-tenacity alloy steels, specially as regards toughness and resistance to shock and vibration

In many of the largest steam turbines on land and sea, and even in more ordinary installations where there may seem to be no special liability to erosion and corrosion, a special alloy of iron high in its nickel and chromium contents is used for the blading, with great advantage in the maintenance of high steam economy, this alloy being highly resistant to erosion and completely non-corrodible under all the conditions experienced by steam turbine blading For example, already turbines of no less than 7 million horse power in total capacity are now bladed in whole or in part with such special steel

One of the most interesting developments in modern high-speed tool steels, specially in view of the fact that manganese steel was formerly considered to be practically unmachinable, is the discovery of alloy steels which will drill and cut water-toughened manganese steel, thus making possible a further extension in the many applications of this exceedingly useful material

Great progress has been made in special steels for permanent magnets and in steels of very high permeability at low inductions, also in new non-magnetic alloys of iron Again, there have been important developments in the use of alloy steels for general constructional purposes, for example in the hulls of large vessels where reduction of weight is an important consideration Many other instances might be mentioned, if space permitted, of improvements in alloy steels which have greatly advanced engineering and industrial practice since the year 1910

Importance of Research

If there is one outstanding lesson that has been brought out by metallurgical progress in general and made possible the rise of alloy steels in particular, it is the importance of continual research Also this research, specially where alloy steels are concerned, must be over as wide a field as possible

As an instance it may be mentioned that the laboratories of the author's firm, as well as those of most modern steel works, have for many years used for routine testing as well as original investigations, equipment for every kind of test—chemical, mechanical and physical—with special apparatus for carrying out tensile, bending, endurance, impact, hardness, electrical conductivity, magnetic permeability, hysteresis, measurement of temperatures from the lowest to the highest, the determination of thermal change points and other tests In a single week as many as 12,000 pyrometric observations have been made, and equipment for the microscopic examination and photomicrography of steels at all powers up to 5,000 and even 8,000 diameters is continually in use.

In any appreciation of the great and increasing importance of metallurgical research during the past twenty-five years account must be taken of the part played by our universities in the training of metallurgical students, and in many instances conducting valuable research investigations. The special duties and responsibilities of the research laboratories maintained

by firms, and working in direct touch with the conditions and requirements of commercial development, can never be fully undertaken by other institutions or organisations At the same time, metallurgists owe a great debt of gratitude to the universities As an example, it may be mentioned that the training and research work carried out in the laboratories of the Applied Science Department of the University of Sheffield are worthy of the highest traditions of the city, and the establishment of metallurgy as an independent faculty with, quite recently, a special founding course and degrees in foundry science is but one instance of the way in which the authorities are keeping in the fore-front of metallurgical progress The importance of research facilities is equally recognised at other universities, each in its own sphere, but in regard to ferrous metallurgy the University of Sheffield naturally occupies a special position and is second to none in the world

Outside the many and valuable researches carried out at the various universities of Great Britain reference must certainly be made to the important work being carried on continuously by the National Physical Laboratory, originally under the able guidance of Sir Richard Glazebrook, and now that of Sir Joseph Petavel, to whom and his staff, composed of men of scientific eminence, great credit is due This great national establishment is now supported by large annual grants, aided by Parliament through the Royal Society and the Department of Scientific and Industrial Research

The Future

Finally, as will have been gathered in the reading of this article, the continued and increasing use of alloy steels in their many forms is most certainly assured The great value of such products can almost be said to be beyond computation in view of the services they render, and modern civilisation could not be sustained by any other means , they may, therefore, be justly said to be beyond any adequate expression in terms of money

It is scarcely realised how largely further advances of present modern civilisation depend upon alloy steels Take these away and our modern civilisation could certainly not exist, at any rate, on anything like its present high plane, and we should in many respects be cast back to the comparatively unsatisfactory conditions of more than a century ago

It is entirely the production and use of alloy steels which have rendered practicable the bringing into being of engineering and other constructions which would not otherwise have been possible, whether in their employment on land or sea or in the air

One useful alloy after another, new or improved, takes its place in the civilisation which it advances and thereafter it is indispensable unless indeed a still better material can be discovered Progress far beyond the bounds which could be foreseen twenty-five years ago has already been achieved, and the rate of such advance appears likely to continue undiminished Therein lie challenge, inspiration and encouragement for those of the younger generation

Progress in Radio Communication

By Prof. E V. Appleton, F R S , Wheatstone Professor of Physics, King's College, London

It is a matter worthy of note that the remarkable progress of radio communication during the last quarter of a century has proceeded largely from the exploitation of the properties of that late-nineteenth century discovery, the free electron. For it is no exaggeration to say that practically all the instrumental progress of the period is connected in some way with that wonderful device, the three-electrode electron tube, while we now realise that the spectacular annihilation of distances in round-the-world communication by wireless is only brought about by the beneficent influence of free electrons at high atmospheric levels. Another significant feature of the period is that radio developments have had an unusually marked influence on human intercourse for, through broadcasting, there has been introduced a new and permanent feature of social and cultural enlightenment while, by way of the oversea wireless telephone, the different parts of the Empire have been brought into a closer unity which from time to time has been sealed by personal messages of greeting from His Majesty the King to all his subjects throughout the world

In 1910 the utility of wireless communication was regarded as being largely concerned with increasing the safety of life at sea. Public interest was, in 1912 for example, stirred by the case of the *Titanic* which, with some 3,000 people on board, struck an iceberg on her maiden voyage

across the Atlantic Several ships picked up her wireless distress signals and raced to the rescue Unfortunately, the *Titanic* had sunk when help arrived, and only 900 persons were saved, though it is clear that without the aid of wireless all would have been lost The first of a series of international conferences concerning the safety of life at sea was held in the following year, though it was not until after the War that stringent regulations concerning the provision of wireless equipment for ships of above a specified tonnage were put into force

Technicians were, at first, slow to recognise the potentialities of the instrument which was to revolutionise the subject, for it was not until 1913 that Armstrong, Meissner and Round independently discovered that the three-electrode valve, which de Forest had invented so far back as 1907, was capable of generating continuous electrical oscillations, and not until after the War was general use made of it in wireless telephony Rather was attention being paid at that time to the possibilities of the Poulsen arc, and the different types of alternators designed by Goldschmidt, Alexanderson and others The general tendency before the War was, in fact, to use arcs and alternators for high-power sending stations and spark generators for short-distance communication between ships

Meanwhile, the fuller utilisation of the three-electrode valve in reception (for detection and amplification) was limited by its inconstancy in operation, which was due to the imperfect vacuum then realisable A notable improvement was effected in this direction by Langmuir who, in 1915, produced 'hard' valves from which all deleterious traces of gas had been removed It thus came about that after the War there was to the hand of the experimenter a device, constant and reliable in operation, which, for sending, would produce sustained waves over a very wide range of lengths, and, on the receiving side, give, in cascade, magnifications of a million-fold. With such a generator, any form of information, whether concerning a sound or a picture, could be transmitted over a distance in the form of a modulation of the waves; while with such an amplifier in use at the receiving end of a wireless circuit, the power required at the sender could be correspondingly reduced.

In the summer of 1922 some of the leading British manufacturers of wireless apparatus approached the Post Office for permission to begin an experimental service of broadcasting speech and music by wireless telephony in this country, and the result was the formation of the British Broadcasting Company. Under the direction of this Company and its successor, the British Broadcasting Corporation, which on January 1, 1927, was incorporated by Royal Charter, there has grown up a great service of sound broadcasting in Great Britain, while to provide listeners with the necessary apparatus for reception there has arisen a new and vigorous electrical industry In the evolution of the modern wireless receiver, commercial research has led to the development of new types of valve filaments giving greater efficiency and to more elaborate types of electrode structures In this connexion special mention must be made of the immediate derivatives of the three-electrode valve, namely, the screen-grid valve for high-frequency amplification and the pentode for distortionless amplification of strong signals

Most histories contain a revolution, and the history of wireless communication is no exception to the general rule At the end of the War, it was regarded as established that long waves were superior to short waves for long-distance communications. The superiority was, in fact, embodied in a transmission formula due to Austin, which was then much employed by radio engineers It is generally thought that the first hint of the extraordinary possibilities of short waves for long-distance communication came from the experiments of amateurs in December 1921 Such experimenters were limited by law to use wave-lengths less than 200 metres but, though operating with very small power indeed, they were able to establish contact with other amateurs 7,000 miles away. During the winter of 1922–23, Dr W H Eccles and H Morris-Airby, using receivers tuned to wave-lengths lower than 100 metres, were able almost every night to pick up signals from American amateur stations, often as harmonics of the sending wave-length. In October 1924 the greatest distance of all was spanned when communication was established between F. Bell in New Zealand and C. W Goyder, a Mill Hill schoolboy.

The revolution mentioned above came at a time when the problem of linking up the Empire by wireless was under discussion In March 1923 the British Government announced the decision to erect a large wireless station at Rugby, capable of communicating with any part of the world. By the end of 1926 this station, working on long waves, as well as a wireless telephone long-wave link between Great Britain and North America, were in successful operation. The latter service, the details of which were worked out by the engineers of the British Post Office in collaboration with the engineers of the American Telegraph and Telephone Company, was the first long-distance

commercial wireless-telephone link to be completed, and its inauguration constitutes a landmark in the history of electrical communication In connexion with Empire telegraph communications by short waves the engineers of the Marconi Company did pioneer work The most notable invention in this field is due to C S Franklin who showed how, by using a special array of aerial wires with a similar array behind, to act as a reflector, it was possible to confine the waves into a directed beam Nowadays, for all point-to-point services, advantage is taken of such directional and economic projection of the waves

To the short wave beam station built by the Marconi Company for telegraph communication to the Dominions, there have been added direct wireless telephone services to different parts of the Empire In these cases also beam senders and receivers, built by the Post Office, are used, with corresponding stations oversea The sending stations are all accommodated at Rugby, while the corresponding receiving stations are situated at Baldock The result of these direct Empire services is that it is not an exaggeration to say that the whole of the Empire is 'on the telephone', with London as the exchange A further experiment in Imperial communication has been the inauguration of Empire short-wave broadcasting by the B B C in 1932 At first it was attempted to provide a two-hours' programme in each of five Empire zones between the convenient hours of 6 p m and midnight, local time, while the B B C publication, *World Radio*, which is the official organ of Empire broadcasting, is published so far in advance that copies of it are available in different parts of the Empire at the appropriate time

On the more purely scientific side, substantial progress has been made during the last twenty-five years, especially as regards the elucidation of electric wave propagation For the propagation of waves along the ground the correctness of the transmission formula of Sommerfeld has been checked by signal intensity measurements made by Barnett and Ratcliffe and by B B C engineers Other quantitative experiments have been carried out to elucidate the structure and properties of the highly ionised region of the upper atmosphere (from 100 km upwards) known as the ionosphere, which reflects wireless waves and makes long-distance radio communication possible The existence of such a reflecting stratum was postulated so far back as 1905 by both Kennelly and Heaviside, but it was not until 1924 that its situation in the atmosphere was established Further investigations have shown that above the Kennelly-Heaviside layer, as the region about 100 km is called, there is a more intensely ionised stratum, the electrical density of which is the factor that limits the shortest wave-length which can be used for round-the-world communication Experiments carried out by Henderson, Rose and others during the solar eclipse of 1932 in Canada have shown that the upper atmospheric ionisation is caused by the photo-electric action of sunlight Due to the influence of the earth's magnetic field on the motion of the free electrons, the ionosphere is a doubly-refracting medium and resolves an incident wireless wave into two oppositely rotating components which experience absorption of different amounts The result is that a reflected wireless wave of, say, 400 metres, is of predominantly left-handed polarisation in the northern hemisphere but of opposite rotation in the southern hemisphere

The ionisation in the upper atmosphere is not by any means constant It is usually denser by day than by night and denser in summer than in winter, but these normal variations are sometimes profoundly upset by manifestations of solar activity The general effect of such activity has been found to be an alteration of the disposition of the electrification and thus of the properties of the ionosphere as a reflecting medium One of the curious things noticed, in our latitudes, is the difference in the effects on long-wave and on short-wave transmission With long waves a solar disturbance which produces a magnetic storm may often increase the daylight signal intensity, but in the case of short wave channels there is almost always a sharp reduction in signal strength In the case of communication over a great circle which traverses high latitudes, the effects of a magnetic storm have been found to be specially marked, which explains why the short wave channels to Canada are more frequently interrupted in this way than are the services to South Africa

On the purely technical side there have been, particularly since the War, many notable contributions to electrical circuit practice, quite apart from the thermionic valve and its derivatives Selection is difficult, but perhaps the superheterodyne circuit of Armstrong and the quartz crystal oscillator of Cady may be chosen as outstanding. The superheterodyne receiver, in which amplification is effected after the conversion of the received signals to a lower frequency, is almost universally used nowadays in commercial practice and in the more elaborate broadcast receivers, while the quartz oscillator, particularly in the hands of Dye and his associates at the National Physical Laboratory, has been developed to provide high-frequency standards of a constancy and accuracy hitherto unattainable.

The Perfection of the Thermionic Valve

By B S. GOSSLING, Research Laboratories, General Electric Co , Ltd , Wembley

THE past twenty-five years have seen the coming of a great change, both in human society and in the individual human life Man has become able to speak to man, and man to mankind, directly and without obstacle of distance Next week, King George will speak, not for the first time, to all his people wherever they may be, and his hearers may well ponder this new aspect of the many-sided relation between Crown and people

For the ordinary man the change is that he is now in ready touch with his fellows, whether actively and personally through the long-distance telephone, or passively and with others through broadcasting As His Majesty has implied in his broadcast words, this means that the tragedies of enforced loneliness and anxiety will soon be erased from the lot of man Music is now within reach of all who will, and whatever there be between learning and laughter that the spoken word can bring to our ears

The principal instrument that has enlarged on this vast scale, and yet without artificiality, the scope of our most natural mode of communication —by voice and ear—is the thermionic valve The attainment by this instrument of its present large measure of perfection—so much even those who best know its faults can allow it—falls easily within the period under review, but springs from the efforts of so many workers in so many countries that it can here be presented only in the briefest of outlines

To begin with, making our start from somewhat less than thirty years ago, there were then two well-recognised and eagerly pursued problems in the art of communication The first quarry in the hunt was a delicate device capable of controlling energy from a local source in faithful response to an incoming signal, such as the attenuated speech-waves on a telephone line the length of which it was desired to extend, or alternatively a weak wireless signal The second aim was a means of generating continuous high-frequency oscillations adaptable to similar faithful control by a microphone for wireless telephony. It was already realised that whatever should solve the first of these would also, when allowed to react on itself, go a long way towards solving the second. There was also in existence a device, the simplest, or diode, form of thermionic valve, in which current passed between electrodes in an evacuated glass bulb ; this offered a means of detecting high-frequency signals by regular rectification, but it was biding its time in face of other temporarily approved alternatives

Ideas had arisen too, in more minds than one, of making such devices more responsive to an incoming signal, but these ideas were as yet vague in the extreme

To complete this outline of the conditions of incubation of the valve as we now know it, we should note the technical position at the time. Amongst makers of electric lamps the production of high vacua in glass vessels, already well advanced as an art in daily practice, was being raised to the higher pitch demanded by the tungsten filament, and was ahead of corresponding practice in the laboratory in some respects at least Acquaintance with pumps in great variety, and the use of many of them, the choice of suitable glass, its fabrication in conjunction with small metal parts, the method of outgassing by 'baking' under vacuum, the use of phosphorus as 'getter' for improvement and maintenance of vacuum, the choice again of suitable metals in addition to tungsten, all these alike were well understood, so that when the need came, any well-equipped lamp works could launch out into valve-making

About the opening of our period, valves, thus incubated, hatched out in various places, and the excitement attending the demonstration of their working was proportionate to the interest of the double problem which they solved A clear explanation of what was going on in them did not, however, come at once The little that was known was reflected in their construction The addition of the third or intermediate electrode left a controlled stream of moving particles as the obvious main connexion between input and the output circuits, but much time was spent, by some at least, before the essential simplicity of the valve and the comparative unimportance of the differences between early types were realised. It is interesting that, before these fascinating devices were turned into reliable tools, a blind eye had to be turned on those factors which need not be taken into account in explaining their action The first of these inessentials was gas ionisation , it had to be realised that, since even the simple diode would work at voltages below the ionisation point, some other agency must be sought. Once this was appreciated a newly-fledged graduate in physics could acquire sound ideas of the main current-voltage relation by working out the solution of a

Poisson's 'space-charge' equation Given this luxuriously simple basis, or even still simpler qualitative ideas on the same lines, the other less important factors could be viewed in proper perspective, and the inherent limitations of the valve could be defined, even thus early, in terms of natural constants In the triode, again, the main point to be appreciated was that one was not required to trace out the motions of particles in transit through the intermediate grid, but only to regard this member as behaving chiefly as a somewhat leaky Faraday screening cage which defined for the region near the cathode a residual field controlling the strength of the current of escaping electrons The German term *Durchgriff* survives as a happy illustration of this point

So much for the valve itself Its action in the circuit had to be deduced by the application of alternating current theory to the relative variations of the voltages applied to the various electrodes and the currents led to or from them Here, contrariwise, the range of relevant premises had to be enlarged by including the displacement currents in minute and at first disregarded stray capacities before laborious algebra bore full fruit in explaining the observed phenomena of amplification and spontaneous oscillation From this work arose, as a kind of shorthand, the array of technical terms such as 'amplification constant' (as compared with its reciprocal synonym *Durchgriff*), 'anode impedance', 'reaction' and so forth now heard out of the mouths of schoolboys

All this work was spread out, with much duplication and overlapping, over the first quarter of the period The effect of the War, sometimes spoken of as a time of great advance, is dubious. It seems in retrospect that intrinsic development may actually have been retarded by the isolation and distraction of those who would in any event have carried on that work The real benefits of this period were indirect; improvement of technique was stimulated by the making of large numbers of valves, and the number of those conversant with the use of them increased with abnormal rapidity After the War, however, the expansion thus made possible did not come at once The valve as a perfected tool had to establish its position, and that on a world-wide scale, by the resumption of the normal exchanges of scientific and technical intercourse, and by further demonstrations arising from free experimental activity In regions outside the United States, preparations had to be made for the insertion of valve amplifiers or 'repeaters' in telephone lines, and over the oceans the extension of direct wireless telegraphy and the introduction of telephony had to be arranged.

It was, then, at about the middle of our period that the valve came into its own For the specialised conditions of long-distance telephony on land-lines the necessary requirement of reliability was early satisfied In wireless the word 'system' dropped out of common parlance, the time for alternative methods was past The discovery of the peculiar transmission possibilities of 'short' waves, for the generation of which valves were uniquely adaptable, brought world-wide range almost as a gift At the same time came broadcasting, with, on the technical side, the need of new standards of faithfulness imposed by the nature of the matter transmitted, particularly music, and of reliability at both ends of the unilateral transmission The waste of energy by thermal radiation from the cathode was progressively reduced The implicit possibility of using free electronic projectiles as the sole connexion between circuit elements was exploited in 'screen-grid' tetrodes and later more complicated types Amplification was carried to the limit set by those disturbances, the 'Shot effect' and the like, arising from the discontinuous structure of matter itself, a real limitation at present The power handled by valves has, however, since the conversion of the anode into a water-cooled metal portion of the envelope, no near upper limit, even without resort to continuous evacuation Uses have also at length been found for thermionic devices employing ionisation in the forms of heavy-current rectifiers of great efficiency, occupying a position midway between the high-vacuum rectifier and the rectifying arc, and of trigger devices which make a virtue of the formerly troublesome discontinuity in current-control in presence of a lavish supply of ionisable material

In the field of communication, the second half of our period has thus been a time of technical consolidation and expansion and of the rise of great social implications During this time also the valve has influenced the course of scientific research as an instrument generally adaptable for use wherever there is a need for delicacy and nimbleness beyond what is conveniently possible for purely mechanical devices Thus, physiologists have been using valve amplifiers for the study of nerve action as revealed by minute electrical changes, valves, sometimes of special design, have replaced sensitive voltmeters and electrometers, thermionic relays have come into use for counting the minute discontinuous occurrences of atomic disintegration, metallurgists have used valve-generated high-frequency currents in furnaces for melting experimental specimens

The position at the present day and the immediate prospect have now to be outlined One point of arrest is to be noted The deliberate design of valves by calculation has progressed but little,

although the physical principles being known this work might be held to have passed into the province of the engineer However, the mathematical functions are generally intractable, and engineers may be excused for their reliance on methods of trial and error As valves get larger, however, such methods are becoming expensive The evolution of the valve is not yet by any means complete, although sometimes, as in television, the valve is an accepted tool and interest centres on other devices at either end of the train of valves

There is still, however, the new field where the periods of electrical oscillation are so short that electron inertia is no longer negligible, but has itself to be brought into service as a main principle of action Here early history has been repeating itself, but the period of groping is now past, theoretical study is difficult but is well advanced Indeed, in contrast to the early days, development has been somewhat in advance of demand. There are also novel devices using free electrons which are not of thermionic origin but are ingeniously obtained by photo-electric or secondary emission

Other new developments may be expected now that valves have made their appearance in the laboratory as appliances built and operated by continuous evacuation in the laboratory for the purposes of research without recourse to the valve maker, for example, for obtaining continuous high-voltage supplies by rectification and very recently also by short-wave oscillation It is not in general to be supposed that valves manufactured by the thousand for engineering purposes or by the million for domestic use are really those best suited for special problems, and it is well that the experimental physicist should take the initiative in meeting his own needs

Finally, new prospects are beginning to open in yet other directions associated rather with the material needs of the human body than with man as an intelligent and social being For some few years high-frequency electrical oscillations of wave-lengths from a few metres downwards generated by valves have been coming into use for purposes as yet perhaps of practical medicine rather than of physiological study, first for surgery, and later for the reinforcement of the *vis medicatrix naturæ*, in part, it would seem, by some kind of inward fomentation, and in part, perhaps, by some more specific action dependent on the existence of natural frequencies in molecules of various sizes or in small bodies of greater than molecular size The achievement of direct specific action on such structural elements would open up wide fields of application to chemical and biological processes far removed from the problems of communication from which the development of the essential instrument took its origin

---

Developments in Aeronautical Science

By PROF F T HILL, Assistant Professor of Aeronautics, Imperial College of Science and Technology, London

THERE can be few applied sciences able to compare with aviation in the rate at which purely academic physical conceptions have been first translated into actual accomplishments and then industrialised, to the extent of the aircraft industry in the short space of a quarter of a century Although the mechanics of flight have been investigated by certain mathematicians practically since the Middle Ages, continuous sustained flight for heavier-than-air machines, or even a useful degree of controlled flight in lighter-than-air craft, was not possible until some device capable of giving out power in the form of a propeller thrust was available, with reasonable weight. The internal combustion engine made this possible, and in 1903 the first power-driven flight in a heavier-than-air machine was made by one of the Wright brothers in the United States The dirigible balloon antedated this achievement by a few years for lighter-than-air craft, although it is not possible to be precise about the date of the first flight owing to the difficulty of specifying exactly what constituted a power-driven flight, as distinct from having merely floated from one spot to another It is certain, however, that at the commencement of the period under review, achievement in either school did not consist of much more than having succeeded in flying for a reasonable period of time, with a very small margin of safety Little attention had been paid to progress towards any severely utilitarian aspects of the problem of flight

In the spring of 1910, Cody, Dunne, Roe and Short were flying aeroplanes of their own design and building in Great Britain. Mr. J. T. C. Moore-Brabazon (now Lieut.-Col. and at present president of the Royal Aeronautical Society) was granted

the R Ae C Club pilot's certificate number one, for making the first officially observed flight in the British Isles, under certain specified conditions The power used varied from a 50 horse-power Antoinette in Cody's machine to a 9 horse-power J A P engine used by Roe Speeds appear to have been about 50–55 miles per hour, and somewhat uncertain, but Cody held one definite record then of having remained in the air for a little more than one hour.

With lighter-than-air craft, the pressure type of envelope was in use then. This was either non-rigid, using the gas pressure to maintain its elongated form, or semi-rigid, with the shaped balloons partly stabilised and supported by a longitudinal framework Airship activity in Britain was almost entirely confined to the British Army Balloon Factory at Farnborough A few small airships were built by Messrs Willows and Co. during the years 1905–12, an outstanding feature of these being the introduction of swivelling propellers as an auxiliary to the normal controlling surfaces, a device still often used on modern airships The Army airships of early 1910 were capable of about 35 miles per hour speed, with a 35 horse-power Green engine, and carried a crew of three

The period 1910–18 can logically be considered to be one of the development of war machines Previous to 1914, the production of machines directed towards a military outlook was stimulated by a War Office competition held in the summer of 1912, and as no equal incentive towards any form of civil aviation existed, the military requirements predominated in design then The year 1912 thus crystallised the attainments of the machines of that day in the military competition, and helped to give definite ideas upon possible lines of improvement A top speed of 75 miles per hour, a lowest speed of 50 miles per hour necessarily accompanying it, a rate of climb of about 400 ft per minute, and a ratio of descent to forward travel with the engine stopped (gliding angle) of 1 in 8, can be taken to be the best performances then Military requirements demanded increase in top speed and climb for fighting purposes, an increased gliding angle for enlarging the area over which the pilot could land in the event of engine failure, and a reduction, if possible, in the already dangerously high landing speed. The development during the whole War period can be summed up by saying that the required improved performances were obtained by the use of greater and greater powers, as these became available from contemporary improvement in the internal combustion engine designed specifically for aircraft work By 1918 these average values (excluding a few freaks for special purposes) can be said to have reached 130 miles per hour for top speed without any corresponding increase in landing speed, 2,000 ft per minute for initial rate of climb, and a gliding angle, although varying considerably with the type of machine, greater than 1 in 8 Size had also increased from a two-seater, say, 500 lb total useful load, to one carrying a load of about 9,000 lb

During this same period the most marked advance in the lighter-than-air craft was that of size, which brought about the necessity for a different construction, the 'Rigid' or Zeppelin type In this a number of separate gas bags are encased in a rigid framework of elongaged cylindrical form, the whole of the load being taken by this structure This construction is used for all large airships to-day The smaller airships were by no means superseded, but they made no great strides in development, being suited to the naval and military duties allotted to them without any drastic alterations By 1918, British rigid airships had reached a speed of 70 miles per hour, carried 1,250 h p in power, with a disposable load of about 27 tons The most outstanding point in performance, in which the airship is still ahead of the aeroplane, was its range At a reduced speed of 45 miles per hour, the rigid airship of that day had a cruising range extending over nearly nine days

The reconstruction period in 1919 allowed attention to be paid to the more scientific side of aircraft design, when the immediate urgency of increased performance at all costs was removed The study of aerodynamic theory produced rules for design resulting in less resistance to motion, both from drag and interference, the net result of which was either increase of speed, greater carrying capacity or wider range, for a given engine-power output Progress in engine development itself gave that power with less engine weight, smaller fuel consumption, and reduced drag for cooling purposes, and concurrently engines of greater power were produced A better understanding of the problem of aerodynamics and theory of structures, added to the increased engine-powers available, led heavier-than-air craft design into specialised channels, and types tended to become, and have remained, with different characteristics depending upon their design criterion To-day the records stand at 440·67 miles per hour maximum speed, 5,654 miles non-stop distance, and more than 57,000 lb useful load carried In none of these cases are such machines of any general use, but the figures indicate the magnitude of the progress made during the post-War period A fair estimate of how far practical requirements modify these figures is obtained if the results of the England-

Australia race of October 1934 are taken This was won by a De Havilland Comet which, although built specially for the race, is of a type that could be used for ordinary everyday commercial flights The flight to Australia, a distance of 11,300 miles, occupied 60 hours 50 minutes flying time, an average not far short of 200 miles per hour Certain military types have normal speeds somewhat higher than this

That such progress should have been made without setbacks is scarcely to be expected, and it is almost paradoxical that such failures, resulting in a train of investigations into their causes, have probably been the greatest help to ultimate success The investigation of accidents and the subsequent building up of design laws that shall avoid a repetition of them, has been one of the responsibilities of the Aeronautical Research Committee in Great Britain throughout the whole of the period under review For example, the gradual increase in speed has produced aerodynamic forces on the wings the precise extent of which had not been anticipated from the experience available at lower speed flight The current theory of structural design was not always adequate to deal with such cases, and wings and control surfaces, lacking stiffness, have developed 'flutter' which has sometimes led to the collapse of the structure of the aircraft It can be safely said that to-day the scientific aspect of this question has now been worked out

Another similar outstanding scientific development is that of landing a machine with maximum safety As the top speed of flight began to increase, it became necessary to investigate the aerodynamics of increasing the speed range, otherwise the landing speed became dangerously high. Even with this as low as possible, pilots are tempted into approaching too near it, and with no margin in hand, they allow the machine's speed to fall below the minimum, and 'stall', usually with serious results This problem has been defeated in two distinct ways the use of aerodynamical devices that delay the occurrence of the 'stall' to a slower speed, or giving the pilot that extra control over the orientation of the machine by which he can neutralise the most dangerous result of a 'stall', the loss of his normal control actions A combination of these two ideas to-day can make the actual flying of a machine as nearly 'fool-proof' as can ever be needed One attempt at dealing with this question has resulted in the creating of a novel type of aircraft—the autogiro. The supporting wings of this machine are rotated in a horizontal plane, windmill fashion, instead of being fixed to the body, as in the normal form of aeroplane Thus, their lift, which supports the machine, depends primarily upon their speed of rotation and not upon the forward speed of the craft This latter may be reduced very greatly by the pilot, but as long as the wings are kept rotating above the minimum speed necessary, the machine will retain its full support

The post-War history of lighter-than-air craft is unfortunately not so happy a tale The rigid airship has grown in size, and has been developed towards the idea of a long-distance transport machine A new German Zeppelin, just about to be launched, will carry eighty-five passengers, ten tons of freight, in addition to accommodation almost comparable with an Atlantic liner Its engines total 5,000 horse-power, and its range without refuelling will be about 10,000 miles This ship, together with a somewhat smaller sister, the *Graf Zeppelin*, now flying regularly, will be the only large rigid airships in commission in the world The generally accepted principle of any vessel that obtains its lift from buoyancy—that its efficiency as a load carrier increases with its dimensions—means that the accompanying increase in cost makes the experiments more susceptible to the difficulties of replacement in the case of failures. Both Great Britain and the United States have discontinued experiments upon large rigids, largely because of the political aspect that has arisen as the result of accidents costly both in lives and material

To sum up the situation to-day, after twenty-five years development, in heavier-than-air craft any speeds, up to those that the ordinary human being can stand without special training, can be flown, provided that the price in power required for it can be paid This price will probably be reduced gradually as more efficient machines are produced, but there does not appear to be any very revolutionary change in sight Sizes of machines such as will give a reasonable degree of comfort are already in existence, and will probably increase, although in theory there should be a limit to this, as the ratio of the structural weight of the machine to the total flying weight must increase This limitation is not serious so long as the size necessary for comfort has been attained. In range it is still uncertain as to whether the direct route across the Atlantic and Pacific Oceans can be flown under unfavourable conditions, at least as an economic proposition Except for these two cases, the range of any normal aeroplane can be such that it is well within reach of organised aerodromes all over the civilised world. In this last case lies the principal hope for the future of the large airship. Its capacity is such that the longest possible journey necessary, that is, half-way round the earth, is probably within its attainments even to-day.

Progress in Turbine Machinery

By ENG.-CAPT. EDGAR C. SMITH, O.B.E., R.N.

IN March 1776 in the reign of George III, Johnson and Boswell spent a few days in Birmingham, and the latter, accompanied by Johnson's old schoolfellow Hector, took the opportunity to see the famous Soho Manufactory of Boulton and Watt. During Boswell's tour through the shops where parts of the engines of Watt were being constructed, Boulton with pardonable pride remarked to him "Here, Sir, I sell what all the world desires to have—Power". Only half a century had passed since Newcomen, in the reign of George I, by the invention of the atmospheric pumping engine, had ushered in the age of steam power, but already steam engines were being erected in mines, factories, breweries and works on an increasing scale, and five years later Boulton wrote to Watt, "The people of London, Manchester and Birmingham are steam-mill mad". Great pioneers as they were, neither Watt nor Boulton, however, visualised the important part steam was destined to play in industry and transport, or that before the death of George III steam would be applied to ships and locomotives. Year by year the demand for power grew, by 1840 the steam engines of the world were estimated to have an aggregate of more than 2,000,000 horse-power, and a century after Boulton had spoken of London, Manchester and Birmingham as being steam-mill mad, the total horse power of stationary and marine steam engines and steam locomotives in the world was estimated at about 30,000,000.

However remarkable these figures may appear, they are comparatively insignificant when placed beside those of the world's power plants to-day. With the passage of time have come improvements in hydraulic turbines, the introduction of oil, gas and spirit engines, the invention of steam turbines and also the construction of power-driven electric generators from which electricity for power purposes can be transmitted over long distances. Any review of the mechanical progress of the reign of H.M. King George V must therefore necessarily have as its central feature the development of prime movers and electric generators. Of the prime movers, the reciprocating steam engine is still the most important unit on our railways, the petrol engine is practically without a rival on the roads and in the air, the oil engine has spread all over the world and has successfully challenged the steam engine for certain classes of ships, the hydraulic turbine coupled to electric generators is used where sufficient water power is available, but for the propulsion of fast vessels, such as warships and liners, and for driving electric generators in steam power houses the steam turbine is supreme. About 96 per cent of the electricity generated in Great Britain is produced in steam stations, the majority of which contain turbo-generators. It is acknowledged that the construction of the first turbo-generator by Parsons in 1884 is as great a landmark in engineering history as the invention of the separate condenser by Watt in 1765, but it is only within approximately the last twenty-five or thirty years that the steam turbine has surpassed in size and power the great reciprocating engines which were the direct descendants of the rotative engines of Watt.

When shown at the Inventions Exhibition of 1885, the first turbo-generator of Parsons, with its high speed of rotation (18,000 r.p.m.) and its extravagant steam consumption (129 lb. per kilowatt hour) excited no great interest and raised no great hopes. It contained, however, all the essential elements for success, and ten years later Parsons was building his first 350-kilowatt turbo-generator and also the 2,000 h.p. turbines for the famous *Turbinia*.

Six years later a great advance was made by the construction of the 1,250 kw. machines for the city of Elberfeld in Germany. These machines had a steam consumption of only one seventh that of the original turbo-generator, and their success paved the way for further developments. One of the finest and most efficient machines running at the time of the accession of King George V was a 5,000 kw. turbo-generator at the Carville power station of the Newcastle-upon-Tyne Electric Supply Company. Supplied with steam at a pressure of 200 lb. per sq. in. superheated to 508° F., this machine revolved at 1,200 r.p.m. and had a steam consumption of 13·19 lb. per kwh. The record set up by this machine was surpassed by that of a far larger turbo-generator of 25,000 kw. ordered in 1911 from Messrs. C. A. Parsons and Co., Ltd., for the Fisk Street Station of the Commonwealth Edison Company of Chicago, U.S.A. In this case the speed was 750 r.p.m., the steam pressure 200 lb. per sq. in., the steam temperature 588° F. and the steam consumption 10·42 lb. per kwh. or about one twelfth of the original machine. Ever since then, by improvements in design, the utilisation of many inventions, the employment of superior materials, by increasing steam pressures and temperatures and by many other means, it has been possible to construct turbo-generators still

more efficient and of greater and greater capacity, the present limit in size being marked by the 208,000 kw machine of the State Line Power Station, Chicago

In Great Britain, the limit of size is marked by the 105,000 kw turbo-generator now being erected in the Battersea Power Station of the London Power Company by the Metropolitan-Vickers Electrical Co, Ltd The installation of such machines is one of the outcomes of the extended use of electricity for industrial and domestic purposes, brought about partly through the work of the Electricity Commissioners and the Central Electricity Board, which have been responsible for the erection of the National Grid In the latest report of the Central Electricity Board, it is stated that the production of electricity in Great Britain during the past five years has increased by 50 per cent Co-ordination in the electric supply industry, too, has led to the closing down of uneconomical stations and the erection of many new stations, of which Battersea is but one Full descriptions of these stations have appeared from time to time in the technical press and from these have been taken a few particulars of turbo-generators which illustrate current practice In various countries stations have been or are being erected, with steam pressures far in excess of those mentioned below, but these stations are comparatively few

It was perhaps but natural, as the Parsons steam turbine was developed on the banks of the Tyne, that some of the most historic turbo-generators should be found in the Newcastle area. Mention has already been made of the Carville station The latest and most up-to-date station in the district is the new Dunston power station of the North-Eastern Electric Supply Company This station has an ultimate capacity of 300,000 kw, but at present it contains three 50,000 kw machines The steam is supplied at 625 lb per sq in and at a temperature of 825° F The turbines are of the two-cylinder tandem type and run at 1,500 r p m Current is generated by the alternators at 13,500 volts and a frequency of 50 cycles An interesting feature is that the steam leaving the high-pressure cylinder is taken at a pressure of 115 lb per sq. in to re-heaters and is then passed to the low-pressure turbine at a temperature of 800° F

One of the most important stations in the Midlands is the Hams Hall station of the Birmingham Corporation, the first part of which was opened by the Duke of York in November 1929 It is designed for an ultimate capacity of 240,000 kw. but there is ample room for its expansion to 1,000,000 kw. if required. Steam is supplied from pulverised-fuel fired boilers at 375 lb. per sq. in. and 710° F. to 30,000 kw turbo-generators running at 1,500 r p.m., generating current at 11,000 volts and a frequency of 25 cycles In the north-west, the Clarence Dock power station of the Liverpool Corporation has the highest thermal efficiency of any station in Great Britain, namely, 26 06 per cent It is unique in being built on the floor of a disused dock Designed for an ultimate capacity of 400,000 kw, with eight 50,000 kw turbo-generators running at 1,500 r p m, it has at present three machines generating current at 7,250 volts and a frequency of 50 cycles The steam pressure is 450 lb per sq in and the steam temperature 750° F The station began work in 1931, and tests of the steam-raising plant showed an efficiency of 86 45 per cent, while the thermal efficiency of the turbines was 30 4 per cent In the construction of the generators, advantage was taken of electric welding By using welded frames for the stators instead of cast frames, no less than 16 tons weight was saved

It would be possible to trace the development of power station practice from the power houses in the London district alone, for it was in Holborn in 1882 that the first central station in the Old World was opened, while at Deptford, Ferranti built what has been called the "forerunner of modern power stations". Several big companies to-day serve the metropolitan district, and the London Power Company has six 'selected' stations for the purposes of the Electricity Act of 1926 Of these, Deptford West took the first place for thermal efficiency among British stations in 1931, while at Battersea is being installed the 105,000 kw turbo-generator referred to above The Battersea station is designed for an ultimate capacity of 400,000–500,000 kw The machines at work at the present time consist of two 69,000 kw three-cylinder turbines driving generators delivering current at 11,000 volts. The boiler pressure is 625 lb per sq in and the highest temperature of the steam is 875°–900° F This station is equipped with an elaborate plant for preventing the emission of sulphurous fumes from the chimneys Lastly, brief mention may be made of the Barking power station of the County of London Electric Supply Co, the first part of which was opened by H M the King ten years ago. The largest set at that time was a 35,000 kw turbo-generator, but the station now possesses two 75,000 kw machines using steam at 625 lb pressure and 825° F temperature In these turbines steam is 'bled' from four different points for the purpose of feed heating. The station has at present a capacity of 390,000 kw.

From the first, the steam turbine had one particular advantage over the reciprocating engine for driving electric generators, inasmuch as it was

most efficient at high speeds When, however, it was applied to marine propulsion, owing to the inefficiency of propellers at high speeds, a compromise had to be made. Yet its inherent qualities led the marine steam turbine quickly to surpass the turbo-generator in point of size, and only ten years elapsed between the debut of the *Turbinia* at the Diamond Jubilee review of 1897 and the construction of the 70,000 h p turbines of the *Lusitania* and *Mauretania* and the adoption of steam turbines for all classes of warships except submarines When referring to the steam turbine in his Gray Lecture to the Institution of Mechanical Engineers in 1930, Eng. Vice-Admiral Skelton said : "Its application is one of the few important marine changes which were made without any set-back, and the initial success and the rapid extension of the system is undoubtedly attributable to the experience gained in its long and gradual development under proper conditions on shore, no less than to the soundness of the conceptions of the inventor and his thorough exploratory work in connexion with the marine application"

It had been realised quite early that in ships it would be an advantage to have some form of reduction gear between the turbine and the propeller, and the development of steam turbines afloat during the last twenty-five years presents several aspects, first the progress with direct driving turbines, secondly the use of turbines coupled to the propeller shafts with either mechanical, hydraulic or electric transmission gear and thirdly the combined use of reciprocating engines and turbines The most notable direct-driven turbine ships of the last quarter of a century include the *Aquitania* (62,000 h p), *Berengaria* (65,000 h p), *Majestic* (84,000 h p) and the *Leviathan* (82,000 h p) ; and large warships such as the *Iron Duke* (31,000 h p), *Malaya* (75,000 h p) and *Repulse* (112,000 h p) Helical-toothed reduction gear, tried out by Parsons in the *Vespasian* in 1909, was adopted in turbine-driven cross-channel vessels and destroyers in 1911 and quickly came into favour By September 1919 the total horse-power of geared marine turbines completed or under construction was about 18,000,000 The use of gearing enabled the efficiency of both turbines and propellers to be increased, turbines of 20,000 h p with gearing being equal to turbines of 30,000 h p without gearing H M S. *Furious* (90,000 h p), H M S *Hood* (144,000 h p) and H M S *Nelson* (45,000 h p) all have geared turbines, as also have the modern Atlantic liners *Bremen*, *Europa*, *Conte di Savoia* and *Rex*, while the machinery of the *Queen Mary* will be of this type

Hydraulic transmission between the turbine and the propeller has never been extensively used, but electrical transmission, first used on a large scale in the United States Navy, has made rapid strides The French liner *Normandie* is fitted with electric drive, and will have four main turbo-generators of 34,200 kw delivering current to the motors on the propeller shafts, the whole plant rivalling in size and interest the machinery of a big power station

Marine engineering practice has sometimes forged ahead of and sometimes lagged behind land practice, but to-day it tends to run on parallel lines Progress during the last twenty-five years has been due to many eminent engineers, among whom the inventors of steam turbines, such as Parsons, De Laval, Curtis, Zoelly and Rateau, hold the place of honour

News and Views

Prof. P. Kapitza and the U.S.S.R.

IT is common knowledge in scientific circles that Prof P Kapitza, director of the Royal Society Mond Laboratory at Cambridge, and Messel professor of the Royal Society, has been detained in Russia since last September by order of the Government of the U.S S.R. Kapitza came to England as a member of a Russian scientific commission in 1921. He soon started to work as a research student at Cambridge under the supervision of Lord Rutherford, and after some preliminary work on radioactivity he commenced work on the production of intense magnetic fields, and in 1925 a new laboratory, financed by the Department of Scientific and Industrial Research, was opened for the work. By the use of a special alternator, Kapitza was able to produce fields up to 300,000 gauss, and to carry out experiments showing the existence of new phenomena in conduction and in magneto-striction. Since most of these phenomena are more pronounced at low temperatures, a hydrogen liquefaction plant was added in 1929, and in 1930 the Royal Society made a special donation of £15,000 to enable a new laboratory to be built to house the original apparatus, together with a helium liquefaction plant. It was characteristic of Kapitza that he was not satisfied to take over existing designs of helium liquefiers, but began immediately to work on the construction of a new type of liquefier which required no liquid hydrogen. This liquefier is an illustration of Kapitza's special technical gift, for it incorporates a piston type engine, which works down to the temperature of liquid helium. This liquefier, which was described in NATURE of May 12, 1934 (p. 708), was perfected last summer, and Kapitza was able to carry out preliminary experiments using strong magnetic fields combined with helium temperatures before leaving for Russia in September to attend the Mendeléeff Congress.

THROUGHOUT these years of developmental work, Kapitza had visited Russia almost every summer. During these visits he gave lectures and advised on the construction of new institutes, and it was known that he had at one time been offered the directorship of an institute in Russia, but Kapitza himself considered that conditions in the U.S.S.R. were not favourable for the development of his work. It came, therefore, as a shock to his colleagues to learn in October that Kapitza's return passport had been refused, and that he had been ordered to begin the construction of a new laboratory in Russia. The reasons underlying this action may be inferred from the following statement from the Soviet Embassy which appeared in the *News-Chronicle*:—"Peter Kapitza is a citizen of the U.S.S.R., educated and trained at the expense of his country. He was sent to England to continue his studies and research work. . . . Now the time has arrived when the Soviet urgently needs all her scientists. So when Prof. Kapitza came home last summer he was appointed as director of an important new research station which is being built at Moscow." This commandeering of Kapitza's services on behalf of the U.S.S.R. ignores the personal and psychological factors involved, as was pointed out by Lord Rutherford in a letter to *The Times* of April 29. A man of Kapitza's highly-strung type must inevitably be profoundly disturbed by a sudden frustration of years of work, and it comes as no surprise to his friends to learn from reliable sources that his health has already been seriously impaired by anxiety and strain. The right of the Soviet to retain Kapitza in his native country can scarcely be questioned, but from the point of view of international science we venture to express the hope that he may be permitted to return to Cambridge to complete the investigations with the remarkable plant designed by him and installed in the Royal Society Mond Laboratory at the University.

Retirement of Sir Peter Chalmers Mitchell

LAST summer it was announced that Sir Peter Chalmers Mitchell was to retire from the post he had held for more than thirty years as secretary of the Zoological Society of London (see NATURE, Aug. 25, 1934, p. 280). At the annual meeting of the Society held on April 29, Sir Peter formally vacated the secretaryship and his successor, Prof. Julian S. Huxley, took his place. Sir Henry Mahon and Prof. J. Stanley Gardiner presented Sir Peter with his portrait, painted by Mr. William Nicholson, on behalf of some 1,250 members of the Society; very appropriately, the background of the portrait includes a map of the Whipsnade estate, with the development of which Sir Peter's name will always be associated. The response to the appeal for the portrait was so generous that it has been possible to send each subscriber a reproduction in colour of the portrait and also to present to Sir Peter a personal memento. The Duke of Bedford, president of the Zoological Society, in moving a resolution of thanks to Sir Peter for his many years of active and inspiring service to the Society and to science, stated that whereas in 1902 the Society's Gardens in Regent's Park had 69,500 visitors, in 1934 the number had increased to 1,690,000, while the Society's high reputation as a scientific body has been similarly enhanced. The Society has been a pioneer, under the guidance of Sir Peter Chalmers Mitchell, in the improvement of the conditions under which animals are kept in captivity. On the more strictly scientific side, mention should also be made of the valuable investigations carried out by the succession of anatomists, pathologists and other workers who have been encouraged by Sir Peter to study the Society's collections.

King George's Jubilee Trust

No social change of our time is more significant than the way in which leisure has ceased to be the privilege of a few and become the concern, if not indeed the lot, of the many. In the problems which leisure now presents, there is none more serious and pressing than those which it presents in adolescence. The Jubilee Trust inaugurated by the Prince of Wales at St. James's Palace on March 1 is designed specially to deal with such problems, and a further reference to its objects was made in an appeal broadcast by His Royal Highness on April 12. The main objects of the Trust are to provide more and better facilities for the recreation and guidance of the younger generation, to encourage the cultivation of abilities, craftsmanship and all those outdoor interests and activities which make for mental and physical fitness. The Trust will assist, strengthen and extend the work of the many voluntary organisations in existence, the work of which is to promote the welfare of the boys and girls of Great Britain. It will enable similar movements to be started in places at present untouched, particularly through lack of local resources and the need of help from a central source. It should encourage co-ordination of effort and prevent the waste of money and effort in overlapping.

APART altogether from its direct activities, the existence of the Trust should encourage a more enlightened and generous attitude to the many problems which arise in regard to juvenile employment and leisure. It should lend powerful moral support to all agencies which are concerned with the education and recreation of young persons, whether in relation to industry or to citizenship. It may provide a focus from which powerful support will be forthcoming for all efforts to deal wisely with the tragedy of juvenile unemployment, with excessive hours of work or with any other matters which hinder the normal development of citizens possessing the qualities of physical, mental and spiritual fitness and ideas of service which make a people great. The Jubilee Trust aims at dealing with the most crucial educational task of the time—that of guarding from the worst dangers of unemployment or unsuitable work at the most critical time of their physical, moral and mental development that large section of our young people between fourteen and eighteen years of age who are drifting into manhood and

womanhood with little guidance, and it should inspire not merely protective or remedial measures but also courageous efforts to deal with the root causes

Chemical Industry at the Brussels Exhibition

PUBLICITY is a kind of vitamin or hormone essential for the proper growth of an industry Like those accessories, it needs to be used constantly, judiciously and in appropriately small doses, an excess may do more harm than good, and the different varieties are more or less specific in their action After a period of unrestrained enthusiasm, during which we sought rapidly to restore supposed deficiencies in vitamins of every alphabetical designation, we have learned to submit our requirements to the examination and prescription of experts, likewise we are learning that the best publicity is that which is well planned and well informed, that which is presented through the right channels by those best qualified, and that in which reality and literal truth are the corner-stones The British chemical industry has been represented at many exhibitions, but for many years no demonstration of its ramifications and of the excellence of its products has been so comprehensive as that which has been arranged for the Brussels Universal and International Exhibition, 1935, opened by King Leopold on April 27 The exhibit, which is located in the British Government Pavilion, has been organised by the Association of British Chemical Manufacturers on a national basis, all sections of the industry have co-operated in its organisation and industrial firms have sunk their identity in order that the display might be truly national. It has been designed to show, by a series of tableaux, the modern applications in industry of selected chemicals There are six main sections heavy chemicals, agricultural chemicals, dyestuffs, coal-tar products, fine chemicals, and pharmaceutical chemicals, there are also exhibits of rayon and of the products of the new plastics or synthetic resin industry

EVERY other industry depends to-day on the chemical industry, whether in the raw material, in the means of manufacture, in testing and control, or in the finished product. New industries have been created by the application of discoveries and inventions relating to chemical substances, old industries, such as agriculture, have been given a helping hand, as in the form of fertilisers and sprays A clear impression of the degree to which industrial chemistry and chemical industry play their part in national life and in individual well-being is offered by the booklet which the Association of British Chemical Manufacturers has prepared in connexion with the Brussels Exhibition. The English edition—others in French, German and Spanish are being prepared—is of much interest apart from the exhibits which it describes; it is a waistcoat-pocket guide to the British chemical industry rather than the programme of a show. It gives a brief account of the part which Great Britain now plays in supplying with its chemical products not only its own needs and those of the Dominions and Colonies, but also the wants of foreign countries less happily placed The booklet contains a list of firms and organisations which have contributed to the exhibit, together with statements of their principal products This is the right sort of publicity, dignified, informative, accurate and interesting The exhibitors deserve their due reward

Aborigines and Australia

A CABLE from Adelaide in *The Times* of April 26 announces the composition of a Federal Board of Inquiry, which has been set up to investigate the treatment of the Australian aborigines The Board will consist of three members, Prof J B Cleland, professor of pathology in the University of Adelaide, Mr White, acting Federal Chief Protector of Aborigines, and the Rev J H Sexton, secretary of the Aborigines Friends Association of South Australia The responsibility of the Federal Government of the Australian Commonwealth is limited to the aborigines of the Northern Territories, including the Arunta of the Alice Springs area, famous in the annals of anthropology as the tribes among whom the late Sir Baldwin Spencer and F J Gillen made their epoch-making investigations. Although a liberal policy has been pursued by the Federal Government in the protection of these aborigines, especially in the matter of endeavouring to ensure that they should have free access to their hunting grounds and to the springs and water-holes, allegations have been made recently that the aborigines are being forced off the land necessary to their livelihood Attention has also been directed in a recent report of a Commission in West Australia, to which we hope to refer later, to the inadequacy of the arrangements for dealing with leprosy among aborigines This is a Federal responsibility, a leprosarium being provided at Darwin, at which cases from the various States are received The accommodation, it is stated, is inadequate, causing serious delay in evacuating cases from their point of origin, while, notwithstanding an agitation which has been proceeding for ten years, no steps have been taken towards a systematic examination of the aboriginal populations for the disease

Broadcasting in Great Britain

THE Postmaster General recently appointed a committee to consider the constitution, control and finance of the broadcasting services of Great Britain, including broadcasting to the Empire, television broadcasting and the system of wireless exchanges which will be conducted after December 31, 1936 He appointed as chairman Viscount Ullswater, and everyone will agree that this was a happy choice, but we were surprised to see that the committee did not include any men of science We do not believe that any other country in the world would have appointed such a committee without a representative of science. Mr. Whitley was very proud of the new research department of the B B C and was looking forward to it being a great help in the future Already it has done valuable work, but little reference is made to it in the *B B.C Annual* for 1935 In our opinion,

the addition of two or three scientific and technical men to this committee is necessary. So far as we can see, none of the committee has any real knowledge of the scientific principles underlying the problems its members will have to discuss. We hope that this will soon be remedied It is necessary to consider the instructional and entertainment values of broadcasting, but it would be foolish to neglect the scientific development of the art We have tried to find out from the *Annual* the amount expended in 1934 on research Unfortunately this does not appear, it is apparently included in the general sum of £334,959 mentioned on p 91 for maintenance, salaries, development and research, etc

Science and Social Responsibility

IN the April number of *State Service*, the journal of the Institution of Professional Civil Servants, Prof. H. Levy contributes an interesting article on this topic The social consequences, he says, that have flowed in the wake of technical advance stand now in such clear outline that even scientific men, traditionally concerned only with the internal content of their work and not with its external repercussions, are beginning to lose their complacency In the past, the scientific method excluded from its scope all matters involving prejudice, desire, bias or purpose, and was purely objective in character In the logic of the physical sciences, human desires play no part, but in the social sciences they are fundamental The pursuit of science is essentially a co-operative activity and is therefore socially conditioned It is directed to an end, and that end is its social purpose, but since the direction which scientific investigation takes is in this way socially determined, science itself becomes one of the determining factors of society It improves the technical level of production, it introduces new factors into the way of living for the population, it affects their cultural interests; it creates new needs and therefore arouses new hopes and desires In almost every walk of life, laws of detailed social behaviour on which action is based are already recognised Is it too much to suggest that here in small detail are the kinds of regularities and recurrences that make a science possible? Are we not therefore entitled to expect corresponding regularities, perhaps deeper and more far-reaching, on a large scale, and as a consequence, since society is dynamic, a logic of social change? Since science is itself a motivating factor in that change, its study is a scientific responsibility

British Trust for Ornithology

FIELD ornithologists in the British Isles are making an experiment in co operative research which, if successful, may have far-reaching implications They have a peculiar problem to deal with, partly because the great majority of them are not trained men of science, and yet are being led on to territory where an advanced scientific technique is essential Some of the combined operations recently carried out have been on an impressive scale The census of heronries in 1928 needed some five hundred observers before it was completed, while the great crested grebe inquiry of 1931 and the two-year woodcock inquiry now in progress have each enlisted more than a thousand observers. Naturally such work calls for a high degree of organisation, but until very recently British field ornithologists as such possessed no national organisation whatever Irreplaceable manuscripts, field-notes, photographs, maps and collections of literature or bibliography were got together and dispersed according to the hazards of individual existence A number of prominent ornithologists, including Mr H F Witherby, president of the British Ornithologists' Union and editor of *British Birds*, Prof. Julian Huxley, the Rev F. C R Jourdain, secretary of last year's International Ornithological Congress, and Dr P R Lowe of the British Museum, combined to fill this gap by forming the British Trust for Ornithology as a permanent national trustee for the interests of field ornithologists The Trust itself holds capital funds and assets in kind, such as a library, and collects subscriptions, which enable it to make grants for ornithological research These grants, which at present are only on a very small scale, are being used to develop the nucleus of an Institute of Field Ornithology at Oxford, recognised and administered by the University. A national planning committee for the ornithological programme as a whole has been set up jointly by the Trust and the University

THE Trust's first report just issued shows that, in spite of very cramped finances, a wide range of research has already been undertaken with marked success Special reference should be made to the enterprise of the Trust in starting an experimental annual index of heron numbers, based on a twenty-five per cent sample of the breeding heron population of England and Wales The index for 1934 is given as 102, 1928 being taken as 100 Another interesting point is the linking up of census work on swallows with a study of the size of broods, association with domestic animals at breeding places and occurrence of certain lethal parasites The inquiries into short-eared owl habits during a vole plague on a Forestry Commission estate, and into the effect of the recent drought on great crested grebes, are further examples of the broad range of research which this comprehensive and flexible type of organisation makes possible. The Trust is still in an experimental stage. Inquiries and offers of help should be addressed to the Honorary Secretary, Mr E M. Nicholson, 61 Marsham Street, London, S W 1

Earthquakes in Persia

DESTRUCTIVE earthquakes have recently visited the Persian province of Mazanderan that lies along the southern border of the Caspian Sea The first shock occurred on April 12, and was followed by others of greater severity during the next few days It is stated (*The Times*, April 24 and 27) that 28 villages have been destroyed and about 600 persons killed. The province is one that is seldom disturbed by great earthquakes, though it lies near the important centres of Teheran and Resht. Sir Arnold Wilson, in his valuable paper on earthquakes in

Persia (*Bull Sch Oriental Studies*, 6, 103–131 ; 1930), records two earthquakes in Mazanderan, in 1802 and 1820, that have hitherto escaped the attention of seismologists By the earlier shock, 70 towns and villages were destroyed, while the towns of Semnan and Damghan, to the south of the province, were seriously damaged

Rockefeller Medical Fellowships

THE Rockefeller Medical Fellowships for the academic year 1935–36 will shortly be awarded by the Medical Research Council, and applications should be lodged with the Council not later than June 1, 1935 These Fellowships are provided from a fund with which the Medical Research Council has been entrusted by the Rockefeller Foundation Fellowships are awarded by the Council, in accordance with the desire of the Foundation, to graduates who have had some training in research work in the primary sciences of medicine, or in clinical medicine or surgery, and are likely to profit by a period of work at a university or other chosen centre in the United States or on the Continent of Europe, before taking up positions for higher teaching or research in the British Isles A Fellowship held in America will have the value of not less than £350 a year Full particulars and forms of application are obtainable from the Secretary, Medical Research Council, 38 Old Queen Street, Westminster, S W 1

Announcements

HIS MAJESTY THE KING has conferred his patronage on the fifty-fourth annual meeting and conference of the Society of Chemical Industry to be held in Glasgow on July 1–6 Among the subjects to be discussed are the transport of food by road, rail and sea, problems of water supply, and chemical engineering in the Navy

WE regret to announce the death, on April 27 at the age of seventy-three years, of Prof H. B Baker, F.R S , lately professor of general chemistry in the Imperial College of Science and Technology

DR. GEORGE SARTON, editor of *Isis*, the quarterly organ of the History of Science Society and of the International Academy of the History of Science (Harvard Library, 185, Cambridge, Mass., U S A), has been elected a corresponding member of the Academia de la Historia of Madrid.

THE Ramsay Memorial Fellowships Trustees will consider at the end of June applications for a Ramsay Memorial Fellowship for chemical research, of the value of £250 a year. Particulars of the award can be obtained from the Secretary of the Ramsay Memorial Fellowships Trust, University College, London (Gower Street, W C.1)

THE Linacre Lecture at St John's College, Cambridge, will be delivered by Mr. P. P Laidlaw, pathologist to the Medical Research Council, National Institute for Medical Research, on Tuesday, May 7, at 5 p.m. in the new lecture-room of physiology The title of the lecture will be "Epidemic Influenza . A Virus Disease".

A COURSE of eight lectures on pathological research in its relation to medicine is being given on Thursdays, commencing May 2, at the Institute of Pathology and Research, St Mary's Hospital, W 2 The lecturers are Sir Almroth Wright, Prof E D Adrian (electrical activity of the brain), Dr I N Ashoshov (bacteriophage), Dr C H Andrewes (cancer), Dr R G Canti (cultivation of living tissue), Sir Henry Dale (active substances of ergot), Mr J Henderson Smith (virus diseases of plants and animals) and Dr J Needham (chemical embryology) The lectures are open to members of the medical profession and medical students, without fee

THE seventh Natural Science Congress of the Dutch Indies will be held at Batavia on October 23 26 The agenda will include addresses by Prof R Remmelts and Dr L J C Van Es as well as meetings of sections Further information can be obtained from the Secretariat, Koningsplein Z11, Batavia

A SPECIAL exhibition of welding has been arranged at the Science Museum, South Kensington, and will remain on view until May 15 The exhibits include a wide range of machines used in welding by the oxy-acetylene, resistance, atomic hydrogen and arc processes, and a representative selection of examples of welded work Demonstrations of the first three processes are being given daily at 11–1 and 3–5, and films illustrative of welding are being shown every afternoon in the Lecture Theatre at 4 The exhibition is supplementary to the symposium on welding on May 2-3 organised by the Iron and Steel Institute in co-operation with a number of other technical societies and institutions

APPLICATIONS are invited for the following appointments, on or before the dates mentioned .—An assistant (II) for research in aero engines and accessories at the Royal Aircraft Establishment, South Farnborough, Hants—The Chief Superintendent (May 7) A laboratory research assistant in the Glamorgan County Mental Hospital, Bridgend—The Medical Superintendent (May 15) An assistant (Grade III) for abstracting scientific and technical papers in the Department of Scientific and Industrial Research—The Establishment Officer, 16 Old Queen Street, Westminster, S W 1 (May 15) A head of the Mechanical Engineering Department, Central Polytechnic, Croydon—The Education Officer, Education Office, Katharine Street, Croydon (May 15) An inspector of agriculture in the Department of Agriculture and Forests, Sudan Government—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, London, S W.1 (June 10) A lecturer in mathematics in Huddersfield Technical College—The Director of Education, Education Offices, Peel Street, Huddersfield A principal of the Swansea Technical College—The Director of Education, Swansea An assistant for soil survey work at Harper Adams Agricultural College, Newport, Shropshire—The Principal A lecturer in geography in Armstrong College, Newcastle-upon-Tyne—The Registrar.

The Green Flash at Sunset

OBSERVATIONS of the green flash have frequently been recorded in NATURE, and Lord Rayleigh[1], by simple and beautiful experiments with an artificial source of light and a prism the dispersion of which was equal to atmospheric dispersion, has imitated the chief phenomena of the coloured flash observed at sunset This experimental imitation strongly supported the generally accepted view that the green flash is primarily due to atmospheric refraction, dispersion and differential scattering The discussion following Lord Rayleigh's paper read before the Physical Society indicated, however, that before a satisfactory explanation of all the observed phenomena could be given, further observations were required

The phenomenon is probably by no means so infrequent as is generally supposed, and may even be the rule rather than the exception when the horizon is clear and the observer at a sufficient altitude The rarity of the green flash at sea-level is possibly due to the horizon being too near for the dispersion to be perceptible

Recently I had an opportunity of making a number of observations of the coloured flash on the west coast a few miles north of Auckland from a hill about 180 feet high On one occasion Mr H B Lusk, who had observed the green flash with me from the hill on the two previous evenings, was on the beach at sunset and reported that no green flash was visible, though it was clearly seen by me and by other observers from the hill

On several occasions I observed the setting sun with an $\times 30$ army pattern telescope One evening there was obvious stratification of the atmosphere At the moment before sunset the sun appeared orange-red through the lowest stratum, which was about a third of the diameter of the sun in thickness, orange through a second stratum of about the same thickness and light yellow above The marked turbulence of the rim of the sun appeared to have a horizontal tendency When about a fifth of the diameter of the sun remained above the horizon, the sun appeared orange through the telescope and the turbulent rim was fringed with green, which became more evident as the sun sank Just before the sun disappeared, a small narrow horizontal strip appeared to become detached from the top of the sun. During detachment the ends and upper edge of this fragment were green The green rapidly invaded the strip, which at the moment of detachment was completely grass green in colour, the much larger mass of the remaining sun appearing orange As the sun disappeared below the horizon, the last narrow edge turned bright green before disappearing

On another occasion when the sky was unusually clear, the setting sun was almost too bright to observe with the naked eye. Through the telescope it appeared yellow with the lower part tending to orange. When the sun had set to about four-fifths of its diameter, the turbulent edge of the sun appeared to have a narrow fringe of brilliant violet As the sun set, this changed gradually to a bright spectrum blue A small fragment became detached as in the previous case, but instead of being green was a brilliant blue at the moment of separation The last tiny portion of the sun to disappear became bright blue-green before sinking below the horizon

Although the primary cause of the coloured flash may be atmospheric dispersion, simultaneous colour contrast may very considerably modify the subjective colour effect I had the privilege of seeing Dr J S Haldane's experiments referred to by Lord Rayleigh and have seen other remarkable simultaneous colour contrast effects. Some years ago in Auckland the nearly full moon shortly after sunset appeared grass green. I telephoned to a neighbour asking him to look at the moon and tell me its colour, and was not a little relieved when he reported that it was green I concluded at the time that the effect was due to colour contrast, the sky being highly coloured In the case of the setting sun, the contrast is between the coloured edges or fragments and the more luminous remainder of the sun, not the background

I HAVE read Prof Worley's letter with interest, and can agree with him that the green flash is by no means a rare phenomenon On a recent trip to the West Indies, I saw it three times out of a total of five sunsets observed, using a field glass $\times 7$. It was just about as conspicuous as the experimental work would lead one to anticipate Circumstances unfortunately prevented my observing further sunsets, as had been hoped

Striated Muscles of an Amber Insect

IT is well known that arthropods found in Baltic amber are unusually well preserved, so that even the minutest features of their chitinous structures are plainly visible under considerable magnification The internal organs, however, are usually completely disintegrated, nothing but the amber mould of the chitinous skeleton remaining. It was therefore something of a pleasant surprise to discover a specimen of an amber fungus-gnat in which the flexor and extensor muscles of the tibia, located in the femur, are so well preserved in all legs, that not only their outlines, but also the transverse striations of the

fibres, may be clearly seen under the microscope at a linear magnification of 300 . 1 (see Fig 1)

The specimen belongs to the British Museum (In 18753, 92 74) and is in the same piece of amber with a spider, forming part of a collection loaned to me for study through the courtesy of the Department of Geology Unfortunately, the wings of the fly are broken off at their base, making identification of the species and even of the genus impossible except by matching with specimens in some other, identified collection Presumably it is a species of *Sciara*, this genus being extensively represented in the Baltic amber The small insert in the photograph shows the fly at a magnification of 15 The femora with the muscles had to be photographed at a magnification of 300 1 with the aid of a low power objective and a high-power ocular, the combination being necessitated by the thickness of the amber [In reproducing the photograph, it was reduced to $\frac{3}{5}$] The best results were obtained with infra red rays

FIG 1 Infra-red photograph of a Baltic amber fungus-gnat (*Sciara* sp ?) showing transversely striated flexors and extensors in the legs (× 180) Insect (× 15) Photographed by Prof Petrunkevitch

The reason why the striations do not show nearly as well in the photograph as when the specimen is examined directly under the microscope, lies in the fact that one cannot change the focus during exposure, or increase its depth sufficiently to show all lines at the same level.

So far as I know, this is the first instance of striated muscles found in fossil insects. In 1902, Bashford Dean[1] described and figured transversely striated muscles in a Devonian shark. Vertebrate muscles, unprotected by anything but an easily perishable skin, are quick in deteriorating, yet for the same reason, under favourable conditions, may be penetrated by soluble salts serving as a preservative Not so in arthropods Only rupture of the outer skeleton admits fluids to the inner organs This particular gnat must have been injured at the time that it was caught in the still fluid gum, which oozed through the wound, entering the legs and embalming the muscles before they had time to decompose

Nature of the Thermal Agitation in Liquids

THE accompanying photographs (Fig 1) represent the analysis by a Fabry-Perot *étalon* of the structure of the 4046 A , 4078 A and 4358 A radiations of a low-density water-cooled mercury arc, after they are scattered through an angle of 180 by a column of carbon tetrachloride liquid In each case, two different temperatures of the liquid column (30° C and 70° C) were employed, the exposures being as nearly as possible otherwise under identical conditions

The choice of a Fabry-Perot étalon as the high resolving power instrument and of carbon tetrachloride as the scattering liquid were both determined by experience gained in this particular field of research[1] It will be seen that a 40° rise of temperature produces a most remarkable change in the structure of the scattered radiation The two Brillouin components having a Doppler shift deter-

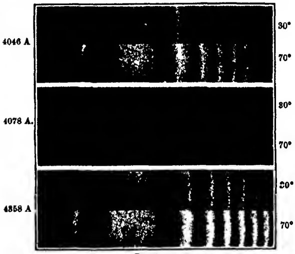

FIG 1

mined by the velocity of sound in the liquid, which are well-defined at the lower temperature, broaden greatly when the liquid is heated, and move in towards the central component, practically closing in upon it The central component at the same time increases in intensity The conception that ordered wave trains of sound constitute the thermal energy in a liquid therefore departs more and more from the actual facts as the temperature of liquid is raised

Use of Hydrogen Cyanide in Fumigation

THE recent tragic death of two children from hydrogen cyanide fumes following the fumigation of their home in Aldershot has directed attention to the need for stricter control of the practice of fumigation and to the need for fuller knowledge of it For some years past I have strongly urged the need for the licensing of *fumigators*, and the question *has*, I believe, received consideration by officials of the

Ministry of Health and of the Home Office While one fully appreciates the difficulties which the licensing of fumigation presents, the dangers to which innocent members of the community are exposed justifies a serious effort to overcome them One firm which supplies the greater part of the hydrogen cyanide used for fumigation purposes in Great Britain is playing its part by restricting supplies to fumigation firms and fumigators of known repute and competency

Fumigation of houses, warehouses and mills, and of foodstuffs and other materials, is much more widely practised than is generally known The recent formation by the Medical Research Council of a committee charged with the investigation of the bed-bug problem as an important factor in slum clearance, and the promotion by that committee of research on fumigation as applied to houses, is an important step in the right direction Until the formation of that committee, research on fumigation and fumigation methods in Great Britain was dependent for financial support almost solely on firms manufacturing insecticides, or on firms directly interested in the fumigation of food-stuffs and other consumable stores, such as tobacco.

The use of fumigants for the destruction of rats on ships has long been recognised, and is indeed insisted on as part of an international campaign against plague, but the use of fumigants against insects infesting food-stuffs and other consumable stores is still in some circles regarded with disapproval, and although tolerated is not encouraged A main argument for this attitude is that if food-stuffs were stored and transported under proper hygienic conditions, there should be no need for fumigation, and that just as preservatives in food-stuffs have been dispensed with by food manufacturers, so should fumigants be unnecessary The two cases are not comparable for a number of reasons. The habits and behaviour of insects are more complex and far less well understood than the biology of bacteria Then the use of preservatives was naturally applied to food-stuffs just prior to marketing and packed in small bulk, in other words, preservation was a factory process. Now infestation of food-stuffs by insects may occur during harvesting and at any stage thereafter until the factory is reached, and the quantity of material to be treated may amount to thousands of tons. It is impracticable to ensure absolute protection of such a large bulk of produce from insect infestation in our present state of knowledge of the insects' biology; and, however desirable it may be that sterilisation of food-stuffs by fumigation should be dispensed with, that is no more practicable at present than to dispense with fumigation practice in slum clearance

Meanwhile, it is surely better ,that the need for fumigation in the marketing of food-stuffs should be recognised, that those firms concerned which are enterprising enough to inaugurate and support researches designed to make fumigation safer and more efficient should be encouraged in their work; and that every effort should be made to prevent fumigation falling into disrepute, mainly because it is not sufficiently recognised as a scientific process and its application is not restricted to those adequately trained in its theory and practice.

Mechanism of Respiration

UNDER the above heading, Prof A. Szent-Györgyi makes the wide statement[1] that respiration consists mainly of a reversible oxidation of succinic and malic acids to fumaric and hydroxy-fumaric (oxaloacetic) acids. Succinic and malic acids are activated by specific dehydrases and "only these two dehydrases seem to be connected immediately with the Warburg-Keilin system"

These conclusions are probably accounted for by the fact that Szent-Györgyi used minced tissues It has been shown by Elliott and Schroeder[2] that, while slices of kidney tissue will carry out a cycle of reactions in the oxidative removal of lactic and pyruvic acids, on mincing the tissue, only the power to oxidise succinate to fumarate and to convert fumarate to malate remains, all the other oxidising agencies concerned in the cycle, as well as various other mechanisms, are completely destroyed.

In collaboration with Z Baker and M Benoy, I have now shown that slices of two types of transplantable rat tumour, a sarcoma and a carcinoma, while respiring at a rate equal to that of many other tissues, are quite unable to oxidise succinic or malic acid These acids, therefore, cannot be the centre of activity in this type of tissue Details of this work will be published shortly elsewhere

Szent-Györgyi also appears to overlook the work of Harrison[3], who has shown that glucose with its dehydrogenase and co-ferment can react with the cytochrome-indophenol oxidase system

Phenosafranine as an Anticatalyst of the Pasteur Effect

ALTHOUGH since Pasteur it has been recognised that in a wide variety of animal and vegetable cells the respiration is able to suppress the appearance of products of fermentation, the mechanism of this effect is still obscure. At present, the use of reagents which specifically interrupt this link between the two main energy-liberating reactions of cells appears to offer the principal means of its investigation In the course of work on the action of reversible oxidation reduction systems on tissue metabolism, I have found that the dyestuff phenosafranine proves to be the most vigorous specific inhibitor of the Pasteur effect yet described.

The active concentration of phenosafranine is with brain tissue 10^{-5} molar, it is therefore some hundred times as active as ethyl *iso*cyanide (Warburg[1]), aminonaphtholsulphonic acid (Krah[2]), glutathione (Bumm and Appel[3]) or phenyl hydrazine (Dickens[4]), and is active in one ten-thousandth of the concentration of potassium chloride recently used by Ashford and Dixon[5]. When slices of rat brain are suspended in Ringer solution containing glucose, in the Warburg apparatus, and phenosafranine in $10^{-5}M$. concentration is added, the essentially carbohydrate respiration (Q_{O_2} in table) of brain continues unimpaired, the respiratory quotient (*R.Q.*) remains at the

carbohydrate level, but the aerobic acid formation ($Q_G^{O_2}$) rises to a value near or equal to that normally found only under anaerobic conditions The acid formed, estimated by Clausen's method, proves to be lactic acid.

Expt. (min)	Medium	Control Q_{O_2}	Control $Q_G^{O_2}$	Control RQ	Phenosafranine 10^{-4} *M* Q_{O_2}	Phenosafranine 10^{-4} *M* $Q_G^{O_2}$	Phenosafranine 10^{-4} *M* RQ
100	Bicarb	− 11 5	+ 2 0	—	− 14 9	+ 15 2	—
90	Phosphate	− 12 8	—	1 01	− 11 6	—	0 98
120	Bicarb	− 13 2	+ 1 7	1 02	− 14 4	+ 11 1	0 98

Thus the complete separation and simultaneous occurrence of carbohydrate oxidation and fermentation is demonstrated in intact animal cells under conditions closely approximating to the physiological

In tumours, unlike most normal tissues, the respiration is inadequate to suppress the lactic acid formation (Warburg[6]), the carbohydrate oxidation is defective (Dickens and Simer[7]) Phenosafranine specifically inhibits the Pasteur mechanism in tumours also :

	Expt (min)	Medium	Control Q_{O_2}	Control $Q_G^{O_2}$	Phenosafranine 3 × 10^{-4} *M* Q_{O_2}	Phenosafranine 3 × 10^{-4} *M* $Q_G^{O_2}$
Jensen sarcoma	60	Bicarb	− 10 8	+ 28 3	− 9 7	+ 44 9
Walker carcinoma	80	,,	− 12 1	+ 20 9	− 8 8	+ 39 5

Thus whilst in both normal and tumour tissue a widespread correlation between carbohydrate oxidation and carbohydrate fermentation normally exists (Dickens and Simer[7]), phenosafranine in both groups of tissue is able, when present in extremely low concentration, to break down specifically and completely the coupling reaction between these two fundamental routes of carbohydrate katabolism in the living cell

Application of Low Temperature Calorimetry to Radioactive Measurements

It is often of importance to determine in absolute measure energy changes connected with radioactive transformations, but only in a few cases has it been possible to employ calorimetric methods for this purpose, since in general the amounts of energy liberated in unit time are too small. The sensitivity of calorimetric measurement can be increased, however, by many orders of magnitude by working at very low temperatures, and it may be worth while to point this out, as low temperature technique is now within the reach of non-specialised laboratories.

Consider a calorimeter consisting of lead. At a temperature of 1·3°, which can easily be obtained with liquid helium, its specific heat is 3,000 times smaller than at room temperature. So the calorimetric sensitivity is increased by this factor if we take the temperature sensitivity as constant. Using a substance like tungsten, with a higher θ_{Debye}, one can increase this factor still further by one power of 10 If one wishes to measure the heat developed with an accuracy of 1 per cent, the temperature must be allowed to change by 1/10°, assuming that the measuring sensitivity is 1/1,000°–1/10,000° The effects can be accumulated over a period of at least ten minutes, as at very low temperatures the thermal insulation can be made nearly perfect, owing to the lack of radiation Thus, using a calorimeter consisting of 1 cm.^{3} of tungsten, one could measure 10^{-9} cal./sec., which is about 1,000 times more sensitive than in the calorimeter of Meitner and Orthmann[1] So, for example, the total heating effect of 10^{-9} gm. of radium situated within the calorimeter could be determined, or the heating caused by the γ-rays from a source of 0 1 millicurie of radon placed 3 cm away from the calorimeter

Cooling the calorimeter below 1° by the magnetic procedure, one can diminish still further the specific heat of the absorbing substance, and at the same time the sensitivity of the temperature measurement is considerably increased by basing it on the susceptibility of the paramagnetic salt, for, in the region where the Curie law holds, the accuracy of temperature measurement is proportional to $1/T^2$ With a substance obeying the T^3 law for the specific heat, therefore, the sensitivity of this method increases with falling temperature with T^{-5}

The specific heat of a paramagnetic salt, however, does not follow the T^3 law, as its specific heat must necessarily be anomalous in this temperature region[2] No great increase in sensitivity could therefore be achieved below 1° by working with a calorimeter consisting of the salt alone. But, of course, this does not apply to an appropriate combination of the paramagnetic salt and an absorbing substance of non-anomalous specific heat

In some preliminary experiments carried out during the past few weeks, Dr Kurti and I nevertheless worked with the unfavourable case of the salt alone in order to be able to use our ordinary apparatus for magnetic cooling[2] We took 1 gm of iron ammonium alum and cooled it down to 0 05°, which in this case was an advantage solely because of the improved thermal insulation[2] In spite of the very small absorption coefficient of the substance for γ-rays, and the comparatively low thermometric sensitivity of this particular apparatus, a sharp rise of temperature set in immediately after the substance had been exposed to the γ-radiation of 100 millicuries of radon at a distance of 2·5 cm (This turned out to be a very convenient way for measuring the specific heat of the salt and we will report soon on the results) Even in this unfavourable case, we could measure 10^{-8} cal./sec., and it should be possible to measure, in a volume of about 1 cm.^{3}, an evolution of heat of the order of 10^{-11} cal./sec., by using a suitable absorbing substance in combination with the paramagnetic salt and improving the sensitivity of the temperature determination

With such increased sensitivity, various problems can be attacked, and experiments in this direction are in progress at the Clarendon Laboratory.

Internuclear Distance and Vibration Frequency for Diatomic Molecules

THE equilibrium internuclear distance r_e and the vibration frequency ω_e for diatomic molecules were connected by Morse in the formula $\omega_e r_e^3 = \text{const} = 3{\cdot}000 \times 10^{-11}$ cm.[2] for many molecules This, however, does not hold accurately, and in fact the constant shows a periodic error Douglas Clark has proposed a modified formula, $\omega_e r_e^3 \sqrt{n} = \text{const}$, where n is the 'group number', and is the number of 'shared electrons', usually the sum of the valency electrons in the atoms composing the molecule This constant varies for each molecular period, and appears to be quite arbitrary Neither of these formulæ is capable of fitting the case of isotopes, for which r_e has the same value, while ω_e depends on the reduced mass

We have considered a formula involving the reduced mass μ, namely, $\omega_e r_e^3 \sqrt{\mu} = \text{const.}$, and examined it with relation to experimental data for non-hydride molecules Using Clark's nomenclature, it is found that for the molecular periods KK, KL and KM which he discussed, the agreement is very nearly as good as with his formula and almost certain to be within the limits of observational error. In addition, it gives identical constants for the isotopes $B^{10}O$ and $B^{11}O$, and for H_2 and HD

The formula also gives consistent results for the LL and MM periods, and it is found that the constant for the KL period is the mean of the constants for the KK and LL periods, and that for KM the mean of KK and MM. Finally, the constant for each period is no longer arbitrary, but is approximately proportional to the number of completed electronic shells in the molecule, the value for the KK period being $10{\cdot}6 \times 10^{-33}$ gm.$^{\frac{1}{2}}$ cm ^{3}.

We hope to publish a fuller account of this work shortly

Raman Spectra of some Deuterium Compounds

USING a high intensity glass spectrograph with a dispersion of 15 A per mm. we have measured the Raman frequencies of tetrachlordeuterium-ethane and *cis-trans* deuterium-dichlorethylene prepared from heavy water. The results are briefly given below, together with mean values of the Raman frequencies (cm.$^{-1}$) of the corresponding light hydrogen compounds taken from earlier measurements[1] for comparison. Intensities are given in brackets.

$C_2D_2Cl_4$: 174(4), 240(8), 287(4), 352(8), 399(1), 532(2), 623(6), 701(2), 739(5), 947(3), 2240(6)

$C_2H_2Cl_4$: 171(4), 236(6), 286(4), 351(5), 395(2), 544(2), 644(4), 761(2), 802(5), 1212(2), 2984(6)

$C_2D_2Cl_2$ (*cis*) : 176(6), 368(3), 515(1½), 689(6), 850(3), 1570(6), 1507(2), 2325(6)

$C_2H_2Cl_2$ (*cis*) 173(6), 406(4), 565(2), 714(5), 806(½), 878(½), 1182(4), 1587(5), 1687(1), 3080(7)

$C_2D_2Cl_2$ (*trans*) : 346(4), 657(1), 759(2), 992(6), 1570(6), 1547(3), 2325(4)

$C_2H_2Cl_2$ (*trans*) : 351(7), 763(2), 846(3), 1271(5), 1578(3½), 1625(½), 1694(½), 3077(4)

The isotope effect is in many cases clearly determinative and indicates the participation of the hydrogens in the different oscillations. Thus the alteration of the C–H frequency is specially strong; in tetrachlorethane, for example, we have:

CH : = 2984 cm^{-1} and CD : = 2240 cm.$^{-1}$ in dichlorethylene:
CH = 3080 cm.$^{-1}$ and CD : = 2325 cm.$^{-1}$.

An approximate estimate of the bond strength, using elementary vibration theory, gives a greater value for deuterium than for light hydrogen in these compounds

We intend to discuss these new results further elsewhere in conjunction with earlier polarisation measurements[2]

X-Ray Study of Recovery and Recrystallisation of Aluminium Single Crystals

To study recovery and recrystallisation after deformation, we have adapted the rotation method of crystal analysis with flat films placed in front of and behind the specimen.

The aluminium single crystals were deformed by extension by 5–16 per cent It is well known

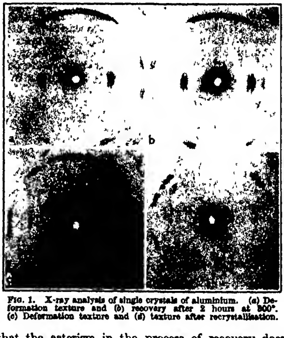

FIG. 1. X-ray analysis of single crystals of aluminium. (*a*) Deformation texture and (*b*) recovery after 2 hours at 300°. (*c*) Deformation texture and (*d*) texture after recrystallisation.

that the asterism in the process of recovery does not change. Distinct changes in the distribution of intensity among the spots, sometimes accompanied either by their shortening or elongation, with simultaneous increase in their sharpness could be seen on some elongated spots on the X-ray pictures taken by back reflection (see Fig. 1, *a* and *b*).

We consider this phenomenon to be the result of the removal of stresses and straightening of the elastically bent separate parts of the deformed single crystal.

Some of the deformed single crystals (10, 12 and 16 per cent extension) have again become single crystals after recrystallisation at temperatures coinciding with those of Karnopp and Sachs[1], but with an orientation absolutely different from that of the deformed crystal (see Fig 1, *c* and *d*)

α-β Transformation of Muscle Protein *in situ*

IN a recent letter[1] we described the prediction and discovery by X-rays of an α-β intramolecular transformation on stretching myosin, and pointed out the close analogy in molecular configuration and elastic properties between myosin and the labile ('supercontracting') form of hair keratin We are now able to report that we have at last succeeded in bringing about the transformation by stretching muscle itself. Details will be given elsewhere at the moment, the change has been demonstrated both in frog's sartorius muscle and in the retractor muscle of the foot of *Mytilus edulis*

Shortly after writing our previous letter, we became acquainted with an almost simultaneous paper by H H Weber[2], describing independent optical and elastic experiments on myosin threads It is interesting to note that Weber's results also indicate, as is shown directly and unambiguously by X-ray analysis, that the myosin molecule is normally in a folded configuration endowed with inherent long-range elasticity

Points from Foregoing Letters

THE green flash at sunset is a common occurrence when overlooking the sea from a certain height, according to Prof F P. Worley, of Auckland, New Zealand In one instance fringes of violet and of blue preceded a final blue-green From this and from the fact that on one occasion the full moon shortly after sunset appeared green, Prof Worley concludes that while atmospheric dispersion may be the primary cause of the coloured flash, the contrast between the coloured edges and the non-luminous remainder of the setting sun may modify considerably the subjective colour effects.

The structure of the softer parts of fossil animals is relatively seldom maintained Prof A Petrunkevitch submits a photograph of the transversely striated muscle of a fungus-gnat (probably *Sciara*) which had been embalmed some thirty million years ago in a piece of amber, now in the British Museum

From the change in the structure of the light scattered by carbon tetrachloride when the temperature of the liquid is raised, Sir C V. Raman and Mr. B V. Raghavendra Rao infer that, as the temperature increases, the thermal energy of liquids becomes less like that of ordered wave-trains of sound

Prof. J. W. Munro appeals for stricter control of the practice of fumigation and for support of research to make fumigation safer and more efficient, so that it may also be applied in the case of insects infesting foodstuffs and other consumable stores.

Dr. K. A. C. Elliott finds that cancer tissue of the rat, while respiring at a rate equal to that of many other tissues, cannot oxidise succinic or malic acids He therefore disagrees with Prof. Szent-Györgyi's generalisation that respiration consists mainly in the reversible oxidation of those acids and believes that Prof. Szent-Györgyi's findings apply mainly to minced tissues.

Living cells derive their energy largely from the oxidation or break-up of sugar-like substances. In the absence of oxygen, lactic acid is formed (fermentation). If oxygen is present the sugar is completely oxidised to carbon dioxide, and the lactic acid disappears (Pasteur effect). Dr. F. Dickens finds that in the presence of traces of the dye-stuff phenosafranine, the respiration of brain tissue produces both carbon dioxide and lactic acid, so that the Pasteur effect is apparently inhibited

At temperatures near the absolute zero, the amount of heat necessary to produce an appreciable change in temperature is very much smaller than at ordinary temperature Taking advantage of this fact, Dr F. Simon has constructed a low-temperature calorimeter which registers 10^{-8} cal/sec He discusses the means for increasing the sensitivity a thousand-fold so as to be able to measure by means of the heat emitted the absolute energy connected with many radioactive transformations

Prof. H S Allen and Mr. A K Longair point out that the simple formulæ which, in a diatomic molecule, connect the vibration and the internuclear distance (magnitudes deduced from the band spectra of the light emitted by such molecules) do not hold accurately They propose to introduce another factor, the 'reduced mass' (equal to the product of the masses of the atoms divided by their sum). This makes the formula fit better and renders the 'constant' for each period approximately proportional to the number of completed electronic shells in the molecule

The spectra of the light scattered by certain compounds of carbon, chlorine and heavy hydrogen ($C_2D_2Cl_2$. $C_2D_2Cl_4$) have been compared by Prof. B. Trumpy with those of the corresponding compounds containing ordinary hydrogen (di- and tetrachlorethane). From changes in the wave-length of some of the spectrum lines, he deduces how the hydrogen atom participates in certain intra-molecular oscillations

Messrs N Seljakow and E. Sows submit photographs showing the changes taking place in the shape and intensity of the spots of X-ray defraction patterns, when single crystals of aluminium are deformed by extension and then allowed to recover They consider the changes to be due to the removal of stresses and straightening of the elastically bent separate parts of the deformed single crystal.

Science News a Century Ago

Work of the Cambridge Observatory

According to the *London and Edinburgh Philosophical Magazine*, at a meeting of the Cambridge Philosophical Society held on May 4, 1835, "Prof. Airy gave an account of recent results obtained at the Observatory, namely, 1st, That the discrepancy of the observations of the obliquity of the Ecliptic at the summer and winter solstices formerly noticed, had disappeared on using the refraction corresponding to a new barometer which stands 1-10th of an inch higher than one formerly used 2nd, That the mass of Jupiter, as determined by observations of the 4th Satellite in 1834, is almost exactly the same as that obtained in 1832 and 1833, namely 1–1048th of the Sun's mass 3rdly, That the time of rotation of Jupiter, as determined by a spot, is 9h, 55m, 21s the spot from which the determination was obtained made 225 revolutions in 93 days"

Marine Meteorology at the Royal Society

At a meeting of the Royal Society held on May 7, 1835, at which Sir John Rennie presided, five papers were read, including three on marine meteorology, communicated by Capt Beaufort, R N They were entitled "Hygrometrical Observations made on board His Majesty's surveying vessel Ætna", "Meteorological Register from the 1st of January to the 1st of November 1834" and "Meteorological Register kept on board His Majesty's Ship Thunder, between the 1st of January and the 30th of June 1834". This last 'register' had been kept by R Owen, Commander, while the other, from January 1 until November 1, 1834, had been kept by Edward Barnett and contained observations made during a voyage across the Atlantic

Cooking by Gas

On May 7, 1835, a correspondent, "M. P.", writing from Hitchin to the editor of the *Mechanics' Magazine*, began his letter: "If any of your long list of readers are smitten with the desire of diffusing useful knowledge, and are in possession of the information I seek, they will thank me for affording them an opportunity of indulging that laudable and fashionable propensity." A gas works had just been erected in Hitchin, and attempts were being made to use the gas for cooking. "M P" said they had tried an apparatus described in the fifteenth volume of the *Mechanics' Magazine*. "It consists," he said, "of nothing more than a cylinder of thin sheet iron, twelve inches high, six inches wide at the bottom and three at the top. The bottom is open and the top is covered with a piece of thin wire gauze." The gas pipe being carried up two inches into the cylinder, the gas jets mixed with the common air and ascended together through the gauze and were set fire to at the top. Results of experiments, "M. P." said, showed that two quarts of water could be boiled by the application of three feet of gas, and as the price of gas was 12*s*. 6*d*. per thousand feet the expense was only a halfpenny. He was, however, desirous of having further information on the subject.

Wheatstone on Speaking Machines

At the Royal Institution on May 8, 1835, Wheatstone delivered a lecture on speaking machines. Mr. Wheatstone, said the *Record of General Science*, gave an account of the different attempts which had been made to invent speaking machines from the time when the oracular responses were delivered at Delphi, through the period when a speaking head was exhibited by the Pope towards the end of the tenth century, and others afterwards by Roger Bacon and Albertus Magnus, with the impositions which were practised upon the credulous, to the present time when the principle of a speaking machine had been developed by Mr Willis Van Helmont was one of the first to write upon the adaptation of the organs of voice to the articulation of the letters He considered that the letters of the alphabet constituted the order in which articulate sounds were naturally produced, by the structure of the tongue and the larynx, that when one letter is uttered the tongue is in the proper position for the pronunciation of the subsequent one Wheatstone gave a demonstration with a copy of a speaking machine which had been invented in Germany, the words 'mamma', papa', 'mother', 'father' and 'summer' being distinctly pronounced The instrument consisted of a pair of bellows, to which a tube was fixed and which ended in a bell, the aperture of which was regulated by the hand so as to produce the sounds

DUBLIN

Royal Irish Academy, March 16 W. B MORTON: Vortex polygons A revision and completion of the classical investigation of J J. Thomson on the stability of the rotation of a set of equal straight vortex-filaments at the angular point of a regular polygon. It is found that the period of rotation is that also of the most rapid oscillations about steady motion, the shorter periods given in the former work for five and six vortices being spurious, and arising from an unjustifiable step in the analysis. The motion of seven vortices is on the border line between stability and instability, one of the oscillations having vanishing frequency, to the first order of approximation. The modes of motion in each case are examined in detail

PARIS

Academy of Sciences, March 18 (*C.R.*, **200**, 993–1076) GEORGES CLAUDE: The campaign of the *Tunisie*. AUGUSTE LUMIÈRE and MLLE. SUZANNE SONNERY: The mode of action of suspensions of carbon introduced into the circulation Intravenous injections of carbon induce hyperleucocytosis, roughly doubling the proportion of white corpuscles SAMUEL EILENBERG: Invariance with respect to small transformations. CLAUDE CHEVALLEY: The definition of Betti groups of closed ensembles. GEORGES VALIRON The Borel directions of meromorph functions of zero order M. LAVRENTIEFF: A class of continued representations. CHARLES LEDOUX: A stroboscopic torsiometer for the determination of the power of a motopropulsive group of a ship. PIERRE SALET: The velocity of light deduced from measurements of stellar radial velocities. The difference between the velocity of light deduced by the spectroscopic method from stellar radial velocities and that of Michelson is not due to a systematic error depending on the hour angle in the star observations ANDRÉ GOUGENHEIM: The accuracy obtained in determinations of latitude by means of the prism astrolabe.

LOISEAU: The rational mechanics of the Euclidian connexions and a necessary form of all physical laws. PIERRE JOLIBOIS: A new arrangement of the diffusion pump. Description, with diagram, of a combined Sprengel pump and mercury vapour pump. PIERRE AUGER, ALBERT ROSENBERG and FRANÇOIS BERTEIN: The characters of two corpuscular components of the cosmic radiation. Experiments confirming the view given in an earlier paper, that there are two groups of primary corpuscular cosmic rays, both of great energy, but absorbed differently by matter. MARCUS FRANCIS and TCHENG-DA-TCHANG: The preparation of thin layers of uranium oxide, U_3O_8, by electrolysis. Deposits of less than 0.2 mgm. per square cm. are adherent, even after ignition. LÉONARD SOSNOWSKI: The artificial radioactivity of bismuth. The excited radioactivity was very weak, but its variation of intensity followed an exponential law. The capture of a neutron by the bismuth nucleus is accompanied neither by emission of a proton nor by the emission of an α-particle. MAURICE DE BROGLIE: Remarks on the preceding communication. JEAN PERREU: The tonometry of saline solutions. VICTOR HENRI and PIERRE ANGENOT: The ultra-violet absorption spectrum of pyridine. Three frequencies, 600 cm.$^{-1}$, 1,029 cm.$^{-1}$ and 1,488 cm.$^{-1}$ are found in Raman, infra-red and ultra-violet spectra. MLLE. CÉCILE STORA: Contribution to the physico-chemical study of photo-sensitive electrodes with colouring matters. JEAN J. TRILLAT and M. PAIĆ: The annealing of pure aluminium. The results of an X-ray study of commercial (99 per cent) and refined (99·993 per cent) aluminium. PAUL LAFFITTE and PIERRE GRANDADAM: The nitride formation of some metals. The production of nitride was studied by measuring the changes in electrical resistance of a wire heated in nitrogen or in ammonia. M. LEMARCHANDS and MLLE. D. SAUNIER: The reaction of the metalloids on the basic oxides. Study of the substance obtained by grinding iodine with mercuric oxide in a mortar: its constitution is $HgOI_2$. PAUL JOB, MME. MARIE FREYMANN and RENÉ FREYMANN: Absorption spectra in the near infra-red of organic and mineral derivatives of ammonia. ARMAND MARIE DE FICQUELMONT: The action of ammonia on the tetramer of phosphorus bichloronitride. The final product is always phosphorus nitride, P_3N_5. P. P. BOUDNIKOFF: The heat of hydration of mortars. JACQUES PARROD: The oxidation products of (*d*-arabino) tetrahydroxybutyl.4 imidazol by nitric acid. LÉON PALFRAY: Some new mineral salts of urea. ROBERT LEVAILLANT: The action of methyl chlorsulphonate on methyl acetate: the action of dimethyl sulphate on acetyl chloride. MLLE. SIMONNE CAILLÈRE: The signification of the phenomenon of incandescence shown by certain antigorites. VALÉRIEN AGAFONOFF: Some considerations on the colloidal part of French soils. MARCEL PICHOT: The imbibition and swelling of the clay of arable soil and their relations with the solids in rivers. DANIEL BARBIER, DANIEL CHALONGE and ETIENNE VASSY: The effect of the temperature of the stratosphere on the spectrum of ozone. CHARLES FABRY: Remarks on the preceding paper. ST. JONESCO: Pollination in certain ephemeral flowers. RENÉ LERICHE and RENÉ FONTAINE: Demonstration by aortography at the thorotrast of the vasodilating effect of peri-arterial sympathectomy. Analysis of this effect. MLLE. JEANNE LÉVY: Experimental alcoholism. Cellular hypersensibility due to acidosis. JAMES BASSET, EUGÈNE WOLLMAN, MME. ELISABETH WOLLMAN and MICHEL A. MACHEBOEUF: Studies on the biological effects of ultra-pressures. The action of very high pressures on the bacteriophages of spores and on autolysins. MICHEL WEINBERG and JEAN DAVESNE: The antitoxic titre and anti-infectious power of therapeutic sera.

IVANOV: Perturbations in the movement of the minor planet (122) Gerda during the period 1904–35, and the ephemeris of the planet for the opposition in 1935. B. NUMEROV: The problem of the determination of the geoid on the basis of gravity observations. S. RODIONOV, M. PAVLOVA, N. REJNOV, N. STUPNIKOV and A. JUZEFOVICH: The short ultra-violet in the solar spectrum. N. ANDREJEV: Measurement of the amplitude of vibration by a finger. O. LEIPUNSKIJ: The steric factor in the equation of the rate of activated adsorption. E. BRUMBERG: A new sensitive polariscope. V. DUBOV: Local tides of the Baltic Sea and their connexion with inundation at Leningrad. F. LOEWINSON-LESSING: Two kinds of correlation between the atomic numbers and atomic weights of chemical elements. J. KERKIS: Does the irradiation of the soma produce mutations in the germ cells? M. TIMOFEJEVA: Frost resistance of winter cereals in connexion with the phasic development and hardening of plants. N. PETINOV: Methods of controlling the grain quality of irrigated wheats. While watering by flooding reduces the protein content of grain, spraying increases both the amount of grain and its protein content. E. SLASTENKO: The *Scorpaena* of the Black Sea.

VIENNA

Academy of Sciences, Feb. 28. MARGARETE HOFFER: Determination of the polonium content from salts of thick layers. HERBERT HABERLANDT, BERTA KARLIK and KARL PRZIBRAM: Fluorescence of fluorite (4). Detection of uranium in fluorites and low-temperature fluorescence. After intense ignition, fluorites show a green uranium band, which serves in estimating the uranium content. The nearer the fluorite is to acid eruptive rock, the more frequent and the more dominant is the yellowish-green fluorescence of the ytterbium. Varying relative concentrations of ytterbium and europium in fluorites from different sources are indicated. R. BRINCKMANN: Comparative researches in the Gosau Basin of the north-eastern Alps. ADOLF MÜLLER and MAURICE DORFMAN: Photochemical behaviour of pyridine, 2-benzylpyridine, papaverine and various derivatives. When irradiated with a quartz lamp in the air, 2-benzylpyridine undergoes two main reactions. In the short-wave ultra-violet, a yellow aldehydic compound is formed, the pyridine ring probably being ruptured. In the long-wave ultra-violet, photo-oxidation to 2-benzoylpyridine and 1 . 2-di-α-pyridyl-1 . 2-diphenylethane occurs; papaveraldine is formed similarly from papaverine. F. HESS: Reply to Arthur Wagner's "Critical Remarks on the Daily Course of Cosmic Ultra-radiation". The reality of the daily course of ultra-violet radiation indicated earlier by Hess, Steinmaurer and Graziadei is confirmed. JOSEF A. PRIEBSCH: Statistical determination of the effect of barometric pressure on ultra-radiation. By a modification in the method of calculating, errors

involved in the statistical method of ascertaining the air-pressure coefficient of ultra-radiation are taken into account. ARMIN DADIEU and HANS KOPPER: The Raman spectrum of liquid deuterium chloride. This spectrum consists of a wide, diffuse band of low intensity and with a maximum at 2041 cm^{-1}. Under analogous conditions, ordinary liquid hydrogen chloride furnishes a band at 2822 cm^{-1}. GUIDO MACHEK: The action of aromatic hydroxy-sulphonic acids on hippuric acid (1). The interaction of hippuric acid and the three isomeric cresols, phenol and β-naphthol yields salt-like molecular compounds of the hydroxybenzene (or naphthol) with glycocoll (liberated from the hippuric acid) in equimolecular proportions. LEOPOLD SCHMID and CHARLOTTE KEMENY: Investigation on *Flores verbasci*. The identity of the acid found, together with the colouring matter crocetin, in these flowers with n-1 14-tetradecandicarboxylic acid is confirmed by the synthesis of the acid from sebacic acid, by way of decandiol. HANS PRZIBRAM: The life of the water-beetle, *Hydrocus piceus*, L. (Col Hydroph), without antennæ. The feelers are not unconditionally necessary to the breathing of *Hydrocus* in water.

Forthcoming Events

CONTENTS

Protection of Aborigines in West Australia

ANOTHER chapter has been added to the annals, too often distressing, of the aborigines of Australia in the report on conditions in West Australia which is referred to elsewhere in this issue (p 798) The Commissioner, Mr H D. Moseley, to whom the investigation was entrusted in 1934, discloses a situation which in certain respects is sufficiently grave, but happily his statement does not endorse the allegations of callousness and brutality in the treatment of the aborigines to which currency has been given

For some time, public opinion in Australia has shown a slow but steady growth in the direction of a more rational and considered policy in the treatment of the aborigines The movement began with the efforts of the late Dr H Basedow some years ago to secure substantial reserves of land, upon which aborigines still living under tribal conditions might be ensured in their liberty to range over an area adequate for the exercise of their primitive economy as 'food-gatherers' in the technical sense of the term employed by the anthropologist Unfortunately this—in the modern view uneconomic—mode of livelihood demands a considerable stretch of undisturbed country for the support of even a small group of people, and although the policy of preserving land for the exclusive use of the native, from which white settlement is barred, of late years has been followed on the whole with consistency, constant vigilance has had to be exercised by anthropologists and others interested in the welfare of the black-fellow to protect him against those who have desired the development of the land for economic uses and to their own advantage. That these efforts have not always been entirely successful is suggested by recent representation to the authorities that the aborigines were in danger of suffering privation through being forced off their hunting grounds by encroachment on their land.

In many respects the aborigines of West Australia have been more fortunate than their fellows in other States. On the whole, conditions have favoured the survival of their tribal organisation to a greater degree than elsewhere except, perhaps, in the central area and in the Northern Territories. The growth of white settlement in West Australia until the opening of the gold fields in the latter part of the nineteenth century was slower and more sparse than in most of the other parts of Australia, and the development of the northern

area, where the nearest approach to untouched tribal conditions still exists, was late The distinction to be drawn between conditions in the northern and southern areas of the State is clearly to be discerned in the report of the Commissioner, where there is a lamentable picture of degeneration as it occurs among the aborigines of the southern area owing to longer and closer contact with white civilisation. It is especially apparent in the pitiable situation of the half-caste, which has arisen out of the undesirable conditions attendant on the proximity of aboriginal camps to the towns

Partly as a consequence of this late development, the problem of the aboriginal in West Australia has been approached on the whole with a greater sense of responsibility and in a more enlightened spirit than would have been possible in an earlier day Policy has been inspired by a genuine, if not always well-directed, desire to secure the well-being of the blackfellow That policy has been applied for some time past through officials who not only had sympathy with the native point of view, but also had knowledge of aboriginal tradition and organisation The crux of the problem has been, and continues to be, the aboriginal spoiled by too close contact with white civilisation, who at best lives by casual employment, and on the fringe of the towns often will end by becoming a more or less permanent burden on the community

To admit that the system of aboriginal protection in West Australia is not without its merits is not necessarily to argue that it is beyond reproach A perusal of the report of the Commissioner on present conditions would do much to remove that illusion, even though there is a suggestion that friction between missionary and squatter may have been responsible for some of the more serious accusations which have been bandied about; while the denunciation of labour conditions on the stations as virtual slavery would appear to belong to that class of hysterical overstatement which seems inseparable from all agitation for reform. Yet, when all allowances are made, it would be difficult to frame stronger expressions of animadversion than certain sections of this report. This can be conveyed only imperfectly in a summary.

In carrying out his duties of investigation, Mr. Moseley wisely did not confine himself to the examination of witnesses, but travelled about the State to inspect conditions himself. In this way he covered some 14,000 miles within the year. On the whole, his report on conditions in the north cannot but be regarded as favourable. The 'bush' native, he agrees, is at his best when left alone, and he recommends that in order to ensure this, the lands at present in occupation by bush tribes should be secured to them as reserves, and that further reserves should be declared, to anticipate closer white settlement Nor does he find that conditions among the natives on the stations, whether privately owned as pastoral farms or Government-owned, are unfavourable Occupation suited to the character and capacities of the native is open to them in pastoral pursuits He criticises the Government stations, however, for not keeping the natives sufficiently fully employed

In these circumstances, Mr Moseley is by no means in favour of the policy of locating all aborigines on reserves Throughout the report he stresses the advantage, and indeed the necessity, of finding suitable occupation for the aborigines On the stations, they are already engaged in suitable pastoral pursuits, and the children receive a preliminary training for these pursuits in the natural order of things Removal to the reserves, even if an attempt were then made to bring them more under the influence of the code of white civilisation, as has been suggested, "would not react to their advantage" In another section of his report, while considering the proposal in connexion with the aborigines of the southern area, he points to the overcrowding of the reserves which such removal would entail

If Mr. Moseley finds little on which to comment in the social and economic condition of the aborigines of the north—even the so-called slavery, whereby no wages are paid, is shown to be beneficial to the native rather than an economic advantage for the farmer—the case is far otherwise when the question of health and provision of medical attention is under consideration. The lack of provision for early diagnosis and hospital treatment is made the subject of severe comment. In fairness, it must be pointed out that responsibility for the inadequacy of the measures for dealing with leprosy, which call for the most serious strictures, are not entirely those of the State, as the care of leprosy comes under the authority of the Federal Government—affording material for consideration by those who advocate that the entire responsibility for the aborigines should be handed over to Federal authority. Mr. Moseley offers certain suggestions for dealing with the provision of medical treatment; but he regards the question as one of such gravity as to

warrant the appointment of a medical man to hold the office of district protector of the aborigines

Stricture of the lack of proper medical attention and hospital accommodation is not confined to conditions in the northern area only, though there, owing to the conditions of settlement, it presents the more serious problem In the southern area it is a problem which can be solved by the enlargement of existing hospital arrangements, although these, it may be mentioned, are also severely criticised, both for their character and their limited extent

Apart from the medical question, the problems of the southern area are essentially different from those of the northern area—the Commissioner notes, with a surprise that is almost naïve, the relative unimportance of the half-breed element in the north The grave problems of the south—and they are indeed grave—are the half-castes and persons of aboriginal descent, the character of the Government settlements, and the situation of aboriginal camps in proximity to the towns Nothing could well be stronger than the criticisms which are levelled against existing conditions. They constitute a grave indictment of the methods of administration, and call for no further comment Here Mr Moseley recommends what is virtually a wholesale clearance and the provision for able-bodied aborigines and the half-castes of Government farm stations, which will allow of agricultural and horticultural allotments, and give facilities for training very much on the same lines as the provision which has been made in Queensland

While conditions such as those censured at the Moore River settlement must be attributed to lack of supervision and as such chargeable to the administration, the report recognises that the system, and not the responsible official, the Chief Protector of the Aborigines, is to blame The Chief Protector has been chained to his office at Perth, and it has not been possible for him to perform his proper function of travelling and inspection. Much of the work of his Department, it is admitted, has been highly successful; but it is pointed out that the system of honorary protectors has not 'functioned, except in the granting of permits for employment.

It is evident that if, and when, the changes, administrative and other, recommended in this report are brought into effect, the Department for the Protection of the Aborigines will be a vastly more costly undertaking than it is at present. To an outside view it certainly would appear that a duty which must necessarily entail a heavy expenditure to make it worth while at all, has suffered in performance from economy In this connexion, perhaps, the relevant figures may be left to speak for themselves Of all the States of the Australian Commonwealth, West Australia has by far the greatest number of aborigines under its control They approach thirty thousand (29,021) Next come the Northern Territories (under Federal control) with 19,336, and Queensland, with 16,957 The lowest is South Australia with 3,407, and New South Wales comes next with 9,724 On the other hand, West Australia is proportionately the lowest in expenditure, her aboriginal administration costing £28,340 per annum as against Queensland, £41,128, New South Wales, £53,124 and South Australia, £23,000 While cost per head would be no fair criterion, owing to the difference in the conditions under which the natives live, for the cost of 'bush' natives is low and small numbers entail relatively heavy expense, yet when every allowance is made, the figure for West Australia seems far too low in comparison with that of other States It would appear that undue exercise of economy has allowed the practice of the State to fall below the standard of modern policy in dealing with the aborigines

Mr Moseley's report is a valuable document Its outstanding feature is its constructive character and its grasp of realities, sympathetic, but unclouded by sentiment In this connexion, however, it must be recognised that it takes a very definite line that does not entirely coincide with the aim of those who have advocated a liberal policy in dealing with the Australian aboriginal Only in part does it endorse the segregation of the blackfellow from white civilisation on reserves, where by contact with white civilisation native organisation has broken down, either in part, as on the stations, or has become wholly degenerate, as near towns and settlements, the measure suggested is occupation and training under supervision or protection along lines which, following present trends, eventually will make the aboriginal self-respecting and self-supporting On no other condition does Mr Moseley see in the degenerating blackfellow and the half-caste anything but a danger to the community If his policy be adopted, it remains to be seen whether the difference in conditions in Australia will favour a course, which, eminently reasonable as it seems in itself, has not as yet proved an unqualified success when applied elsewhere

Reviews

Sir Charles Parsons

Scientific Papers and Addresses of the Hon. Sir Charles A Parsons, O M, K C.B, F.R S Edited by the Hon. G. L Parsons With a Memoir by Lord Rayleigh, with Appendices. Pp. xxviii+260+8 plates (Cambridge At the University Press, 1934) 15s net

THE foreword by Lady Parsons gives the *raison d'être* of this book , she did not live to see its publication It is issued with "the hope of helping the interested reader to appreciate the genius, the perseverance and the indomitable courage of Sir Charles," she writes, and this it does completely , while the personal reminiscences of Lord Rayleigh give us a charming picture of a great inventor from many points of view. An appendix contains a complete list of Sir Charles's published papers from 1885 onwards, and in the volume are printed a number of these sufficient to illustrate the range of his activities and the development of his ideas

The steam turbine and its story occupy the major part of the book Sir Charles Parsons's first published utterance on the subject occurs in a discussion at the Institution of Civil Engineers on a paper on "High Speed Motors" by Gisbert Kapp in November 1885 The earliest paper printed in the volume is dated December 1887 and gives an account, read before the North-East Coast Institution of Engineers and Shipbuilders, of a turbine of early design applied to the working of dynamo electric machines There is a gap until we come to 1897 The application of the compound steam turbine to the purpose of marine propulsion, a paper read, at the suggestion of Sir William White, to the Institution of Naval Architects, tells of the *Turbinia* and her trials during which a mean speed of 31·01 knots was obtained.

Law suits and difficulties over patents had caused delay ; a cruel experience had taught Sir Charles that the path of the inventor is no smooth road ; but the *Turbinia* was a great success and henceforth, with some setbacks it is true—his losses of the *Viper* and the *Cobra* in 1901, though in no way connected with the turbine machinery, were heavy blows—the tale is one of progress and marked success ; the latest paper printed, an address in 1909 to Section G (Engineering) of the British Association meeting in South Africa, describes turbines of 150,000 kilowatts. The indicated horse-power of the *Turbinia* about thirty years earlier had been 1,576 horse-power.

The story, as we follow it in the inventor's own words, is of fascinating interest, and while in this part of the volume it relates mainly to the turbine, we come from time to time on remarks of much wider application Thus in an address to the Institution of Junior Engineers of 1899, Parsons concludes thus "It may be remarked that in the history of engineering progress the laws of natural selection generally operate in favour of those methods which are characterised by the greater simplicity or greater efficiency whether these advantages be great or small"

These were the methods Parsons ever followed until they led him to success His address in 1904 to Section G of the British Association deals with invention. Generally, he writes, "what is usually called an invention is the work of many individuals each one adding something to the work of his predecessors", and then after an account of the internal combustion engine, he asks, "Could not this very valuable invention have been introduced in a much shorter time by more favouring circumstances", and his reply is that "a great deal might be done". As part of his answer he discusses a matter which for long occupied his attention, the exploration by means of a deep shaft of the lower depths of the earth The means for securing in such a shaft a pressure and temperature at which man could work are considered and the estimate is reached that a shaft 12 miles deep would take 85 years to complete, that the temperature at the bottom would be 272° F. and the cost £5,000,000 The address concludes with the statement that the value to the world of the benefits due to the tools left by inventors as a heritage to the human race has on the average exceeded by ten thousand-fold the money spent on making and introducing the inventions

The volume contains two or three addresses of special interest. In 1919, Parsons was president of the British Association meeting at Bournemouth. The year marked the centenary of the death of Watt and thus led to an interesting comparison between the turbine and Watt's engine, to which "consuming from five to seven pounds of coal per horsepower, mankind owes the greatest permanent advances in material welfare recorded in history". Engineering and the War occupies a large portion of the address, which concludes with a reference to the work of the Department of Scientific and Industrial Research constituted in 1915.

In his address to the Institute of Physics in 1924, Parsons again deals with the inventor. He states that at one period during the War, the Boards of Invention and Research received more than 2,000 inventions and suggestions a week, of

which only a minute fraction of 1 per cent were in any way helpful, while scarcely any were of practical value—a result due to the lack of scientific knowledge and methods of thought among inventors

In 1893 Parsons carried out a number of experiments on carbon at high temperatures and under great pressures with the view of obtaining a dense form suitable for arc lamps and the filaments of incandescent lamps The experiments led to an attempt to produce diamonds, an account of these was given in a paper to the Royal Society in 1907, and the conclusion then reached was that in none of the experiments designed to melt or vaporise carbon under pressure has the residue contained more than a suspicion of black or transparent diamond The experiments were continued, and Sir Charles gave a detailed account of his work to the Royal Society in the Bakerian Lecture of 1918 It is a remarkable paper, giving details of a long series of experiments in which almost every conceivable combination of pressure and temperature was tried, but with almost entirely negative results The greatest pressures, estimated to reach momentarily about 300,000 atmospheres, were obtained by firing a 0 303 inch bullet from a rifle into a hole of the same diameter in a steel block partially filled with various substances containing carbon In two cases "a few crystals" were formed (probably from friction) The bullet had grazed the side of the hole, producing a small quantity of molten iron The results of all the experiments are given in an appendix, which is not printed in the volume under notice They are chiefly negative The few that were favourable were generally attributable to the presence of iron This appendix is a wonderful memento of Parsons's "genius, perseverance and indomitable courage". It covers 16 pages (small print) of the Royal Society *Transactions*, it is called an abridged schedule, but it contains a record of some 290 experiments of which about 25 are stated to have shown some indication of diamonds "A few crystals", "some crystals", "one crystal 0·5 mm long which burnt in oxygen", "several crystal plates very like diamond" are the words used to describe these few results In some 90 per cent of the experiments the result is "Nil", meaning no diamond formed

The volume concludes with an account of the auxelophone by Mr. Carnegie, an instrument for augmenting sounds used in 1906 by Sir Henry Wood in his orchestra, and some details of Parsons's work in improving optical glass

In these pages, we see Sir Charles as a great inventor; to realise the man we turn to Lord Rayleigh's delightful memoir. They met at a garden-party in Cambridge during the British Association meeting of 1904, and some six years later their friendship led to a visit to Parsons's home at Ray Lord Rayleigh gives an amusing description of his untidy study with a writing table in the window, from which Lady Parsons occasionally removed cigarette ends, burnt out matches, etc, no housemaid was allowed to touch it, in one corner a gorgeous casket presented to him when made a freeman of the city of Newcastle; on a table at the side a cage containing a white cockatoo, sometimes a trial to his visitors, never to its owner, on the table in the centre of the room a litter of books and papers, but no bookcase and no adequate collection of books of reference, either in the house or in his room at the works, a few simple tools, but no workshop

There is an instructive story from a Cambridge contemporary, a fellow oarsman in the Lady Margaret boat of 1878 One day after a training breakfast, he told the crew he had an engine which is going to run faster than any engine to-day. To the reply "Rot", he produced a paper model, and when he blew into it the wheels flew round, the oarsmen were not interested and to show their contempt put Parsons and his engine under the table, a foretaste of the reception the first turbine was to receive and of the struggles of its inventor Another story illustrates his treatment of a difficulty which threatened to be disastrous It was the morning on which the *Viper* was to run her official Admiralty trial After a preliminary run, the crew struck for higher wages Parsons knew his own mind, and the men walked off the ship He collected a casual crew from the quay, borrowed some men from the firm which had built the boilers and the hull, and with this scratch crew the *Viper* ran her trial and did 37 knots

Though 11th wrangler at Cambridge, in later life Parsons never used his mathematics to solve a problem When invited to listen to some analytical solution, he would say "I like something geometrical I never was very good at analysis and now I have forgotten all I knew".

There is much more of interest in these intimate reminiscences Like most inventors, Parsons was alive to the importance of maintaining a secret until properly protected, hence a bottle of some harmless preparation of carbon was labelled 'ARSENIC', and a simple wooden model of a propeller hidden behind his books He was usually inclined to be silent and listen to what others had to say to him, sometimes he would speak, and as when on one occasion, after discussing some question relating to engines with a naval officer, a chance acquaintance at the club, the latter afterwards inquired, "Who is that contradictious old gentleman? He seems to think he knows more about the engines of my ship than I do myself"

Parsons hated to be beaten Some of his friends, Lord Rayleigh among them, thought there was little prospect of success in the elaborate experiment on the diamond his reply when this view was put before him was "I think it ought to be tried" The trials were expensive Dr Stoney estimated that they had cost £30,000 Parsons's reply was, "We have now made a bit of money and deserve to have some fun". Within a few days of his death, he had dwelt on his hopes of having a shot at the 200-inch mirror for the proposed great telescope at Pasadena

Lord Rayleigh tells us that his purpose has been to bring before the readers of the volume the personality of one of the greatest figures in the engineering world of this or any other time For his successful picture he has well earned the congratulations and the thanks of his readers Our thanks too are due to the Hon G L Parsons for his skilful editing of this selection of the papers of his distinguished uncle R T G.

Manometric Methods in Biology

Manometric Methods as Applied to the Measurement of Cell Respiration and other Processes By Dr Malcolm Dixon Pp xii+122 (Cambridge: At the University Press, 1934) 5*s* net

MANOMETRIC methods have long been used in biology, and when one considers that the earliest specimens of the two principal types of instruments dealt with in the book under review were devised by Barcroft and Haldane so long ago as 1902 and 1908 respectively, it might perhaps appear inappropriate to call the manometric method an essentially new one. Only during the last decade, however, have manometers become so important in many different branches of medical and biological science. The reason for this, as Sir Frederick Gowland Hopkins points out in his foreword, is to be found in the fact that the method has in that time been especially developed for the study of the time course of chemical processes, in homogeneous media as well as in more complex systems containing cells or cell-associations. In many of the fundamental chemical reactions of living cells, such as respiration, assimilation of carbon dioxide or nitrogen and many fermentations, gas exchange takes place, in others it is possible to bring about such exchanges by suitable procedure, as for example, the liberation of carbon dioxide from media containing bicarbonate as a result of lactic acid formation in glycolysis

The main advantage of these methods for biological research is that many phenomena of cellular metabolism can be studied without necessarily interfering with life and growth; it is especially important that many of the fundamental chemical processes occurring in animal organs are kept intact in sections of tissue. The tissue slice method is one of the many improvements of technique initiated by O Warburg; but, independently of the development of the method in his laboratory, workers from the Cambridge School of Biochemistry, Dr Dixon among them, had used the Barcroft differential manometer for the study of reaction rates Much of the experience gained in this work has never before been published, and it is therefore appropriate that the detailed account of both the theory and the practical application of the differential manometer takes a prominent place in Dr Dixon's book

It is difficult to give a more fitting appreciation of the book than that expressed in Sir Frederick Gowland Hopkins' foreword, and it may therefore suffice here to state that it gives a complete survey of the principal types of instruments and methods as well as a critical assessment of their merits and shortcomings There is no doubt that the book will be of great help to all present and prospective users of manometric methods H B.

Antarctic Foraminifera

"Discovery" Reports. Issued by the Discovery Committee, Colonial Office, London, on behalf of the Government of the Dependencies of the Falkland Islands Vol. 10 *Foraminifera*, Part 3: *The Falklands Sector of the Antarctic (excluding South Georgia)* By Arthur Earland Pp 208+10 plates (Cambridge At the University Press, 1934) 37*s* 6*d* net

THE third part of this great monograph on the Foraminifera collected by the Discovery expedition deals with the area called the Falklands sector of the Antarctic Ocean exclusive of the South Georgia waters It lies south of the convergence line where the cold Antarctic water meets the warmer water of the subantarctic area

It was shown in the first part of the monograph that in the Falkland Islands area, north of the convergence line, there are several species of Foraminifera that are characteristic of the Pacific ocean, and in the second part that in the shallow waters round South Georgia there is no evidence of this Pacific influence

In the Antarctic sector the Pacific species were more numerous than might have been expected and in addition to several new species, fully described in this part, there were thirteen species which seem to have a purely circumpolar distribution.

One of the most interesting results of this

investigation is the discovery of a very well-marked difference between the foraminiferous fauna of the Bellingshausen Sea and the Weddell Sea. These two seas are separated by the long tongue of land, called Graham Land, which projects northwards in the direction of Cape Horn. If in the comparatively recent geological times there was a land barrier across what is now Drake Strait, this difference in the foraminiferous fauna between the two seas separated by Graham Land may be accounted for, and the absence of Pacific forms from the South Georgia seas may be due to the diversion of the drift northwards by Graham Land and the comparatively shallow waters immediately north of it.

These are only some of the general considerations which form a distinguishing feature of this important report, and it should prove to be of considerable interest to many workers in other fields of marine zoology as well as to systematists of the Foraminifera.

The third part of the report fully maintains the high standard of excellence set by those that have preceded it, as regards the detailed analysis of the dredgings, the description of the species and the very beautiful illustrations.

Short Notices

Tollens—Elsner Kurzes Handbuch der Kohlenhydrate. Vierte, völlig neubearbeitete Auflage, von Dr. Horst Elsner. Pp. xxii+627. (Leipzig: Johann Ambrosius Barth, 1935.) 39 gold marks.

DR. ELSNER has undertaken the formidable task of reviewing the literature on carbohydrates to the end of 1933, and compressing the material into one volume. This has involved the curtailment or omission of many important topics, such as the glycosides, the biochemical transformations of sugars and technical processes, all of which have been dealt with by experts in recent monographs. The number of compounds described is so great that relatively little space has been available for the critical examination of theories. Nevertheless, properties or reactions which are known to be of fundamental importance in the elucidation of molecular structure have been discussed in considerable detail, and the text has been amply supported by references to original papers at the foot of each page.

Among topics of theoretical interest which are briefly described are stereoisomerism and nomenclature, ring-chain tautomerism, enzyme action, the synthesis of monosaccharides and the investigation of molecular configuration. Monosaccharides occupy the largest section and among these *d*-glucose is naturally prominent. In discussing structural problems, the author stresses the importance of the brilliant studies in methylation by Haworth and his colleagues. Turning to the polysaccharides, it is pointed out that there is general agreement as to the nature and mode of linking of the units in the chain of cellulose. Chemical evidence is here supported by X-ray measurements. The actual length of the chain in the macro molecule is not so simple a problem to settle, and different methods give somewhat different results at present. From chemical evidence Haworth and Hirst have calculated that the chain contains between 100 and 200 glucose units. This result is in fair agreement with that of Stamm, which is based on measurements of the velocity of sedimentation in the ultra-centrifuge, and those of H. Mark and K. H. Meyer, derived from X-ray measurements, while Herzog's osmotic data point to rather higher values. On the other hand, Staudinger's viscosity determinations, which are less general in application and perhaps more empirical in character, generally give still higher values.

The volume is well printed and annotated and should prove to be a valuable work of reference. At the end will be found a useful chart showing clearly the configuration of the various aldoses and the corresponding alcohols and acids.

Air Ministry: Meteorological Office. The Meteorological Observer's Handbook, 1934 edition. (M.O. 191.) Pp. viii+152+32 plates. (London: H.M. Stationery Office, 1934.) 5s. net.

THE previous edition of this useful handbook appeared in 1926. In the present edition the most important change occurs in the section on clouds, which has been revised in the light of the new "International Atlas of Clouds and States of the Sky" published in 1932. There are also modifications relating to observations of the state of the ground and to the scale of velocity equivalents of the Beaufort numbers as derived from records of anemometers exposed at abnormal heights above the ground. Like the "Meteorological Glossary", the "Observer's Handbook" in its special function of giving instructions for the taking of routine observations, both instrumental and non-instrumental, at climatological stations is encyclopædic in scope. We are not sure that the various kinds of precipitated or deposited moisture are in every case so clearly defined as could be desired. Thus though it is implied that 'drizzle' is fine rain, that is, rain consisting of very small drops, and may be heavy, moderate or slight, there seems to be a tendency in official practice to look upon drizzle as a distinct species of precipitation from rain, instead of as one of many varieties of rain which it really is. Snow also may fall in fine 'drizzling' particles. Then surely the most obvious difference between hoar-frost and rime is that the latter, which is frozen fog-drip, collects copiously on leafless twigs and branches of trees.

As suggestions for improvements are asked for in the preface, we should like to recommend fuller and

wider instructions for observing the sky and its portents In these days when official meteorology is becoming so intensively developed, scarcely enough attention is being paid to open-air or landscape meteorology We believe that even official forecasters will see the danger inherent in the growing attitude of mind typified by the countryman who, when asked what he thought about the weather, replied that he had not heard the 'wireless' L C W B

Automatic Protection of A C Circuits By G W Stubbings Pp. viii + 293 (London Chapman and Hall, Ltd , 1934.) 15s net

THE subject of the automatic protection of electrical circuits and systems has grown to great importance, this being very largely due to the growth in size of transmission systems and distribution networks The present book discusses at some length the theory of protective transformers, relays and their interconnexion, and a great deal of useful information is given. The work is presented in a very clear, but not too mathematical a manner, plentifully illustrated with simple line diagrams

The chapter on symmetrical components is extremely valuable. The introduction of a vector operator which imparts rotation through 120° is, of course, a development of the original Steinmetz notation It is, however, necessary that the fundamental principles should be clearly presented, and in this connexion it is unfortunate that a loose statement should have crept in at the bottom of p 81 It is there stated that "the phase voltages, between lines and neutral of a three phase system . . . form a closed triangle" This is not generally true, as can be seen at once if the case be considered where there is a short-circuit between one line and the neutral With a little amplification the statement could be corrected

Further chapters on protection of electrical machinery, cables and transmission lines, and the testing and maintenance of protective gear follow, and a useful bibliography and glossary of terms are given

The work can be thoroughly recommended to all those whose work brings them into contact with the protection of A C circuits. P K

Reports of the Progress of Applied Chemistry Issued by the Society of Chemical Industry Vol 19, 1934. Pp. 840 (London: Society of Chemical Industry, 1935) 12s 6d ; to Members, 7s. 6d

THE publication of this annual volume of reports is an event which few chemists allow to pass unnoticed Indeed, it marks an annual opportunity, particularly valuable to those whose duties prevent frequent contact with colleagues working in other spheres and whose close perusal of current literature is necessarily confined to their own vocational interests, to bring up to date their general knowledge of progress in the principal branches of chemical industry. The twenty-six chapters comprising the reports for 1934 have been entrusted to authors whose competence to assess relative values and to make informed comment is unquestioned, and the abundance of references to original sources of information gives the book the status of a permanent work of reference. It is not easy to select any part as meriting exceptionally honourable mention , nevertheless, Dr E. Stedman should be congratulated on his detailed discussion of the chemistry of the hormones and vitamins, whilst the chapter on intermediates and colouring matters, contributed by Dr E H Rodd and Dr S Coffey, is a masterpiece of thoroughness and compression. The first report, entitled "General, Plant, and Machinery", is attractively written , the section on explosives covers the period 1933-34 A. A E

An Introduction to the Modern Theory of Valency By Dr J C Speakman Pp vi + 157 (London. Edward Arnold and Co , 1935.) 4s 6d net

DR SPEAKMAN'S book is an unpretentious volume, in which he has been content to give his own impressions of modern valency theory, without necessarily indicating the sources of the views assimilated for this purpose The resulting blend is, however, on the whole well-balanced and satisfactory, and is presented in a clear and attractive form. Special interest attaches to a chapter of twelve pages on "The Application of Wave Mechanics to Valency Problems", since these conceptions are fundamental to all modern theories of valency The chapter is written in simple language and contains much that is suggestive It is a matter of regret to the reviewer that the scope of the book did not justify an extension of this chapter to include the explanation of quantum numbers and the interpretation of Pauli's exclusion principle on the basis of wave-mechanics , but such an exposition demands an advanced knowledge of quantum theory, which very few chemists possess, and it is therefore probable that it must be left to a chemically-minded physicist to interpret these conceptions to them T M L

Birds of Great Britain and their Natural History. By W P. Pycraft. Pp 206 + 17 plates (London: Williams and Norgate, Ltd , 1934.) 7s 6d. net.

To the student who wishes to identify the birds of the British Isles, this book has no message , indeed it mentions by name only a very small proportion of the birds of Britain, and in this respect its title is misleading. But it brings together and classifies from a natural history point of view many odd items of information difficult of access to the majority of amateur ornithologists, yet needful for an intelligent interest in the structures and habits of our birds. The treatment of the facts is suggestive and speculative, and while speculation appears to the reviewer to be sometimes hasty and information occasionally inaccurate, there is great merit in the way in which unsolved problems are openly laid upon the table. Works of this type are much needed, since they may suggest to the amateur naturalist lines along which he may still make valuable contributions to science, at a time when the niceties of the racial discrimination of British birds have almost barred him from a field where once he held his own.

The Approach to the Absolute Zero *

THERE is no upper limit to the temperatures which could conceivably be reached; in marked contrast to this, there is on the low temperature side a sharp boundary at $-273 \cdot 1°$ C.—the absolute zero of temperature. The boiling point of the most volatile gas, helium, lies about 4° C. above this limit; by reducing the pressure over liquid helium, it is easy to reach a temperature of 1° K., whilst 0·7° K. has been attained by the use of extremely powerful pumps. The contrast between the ease with which a high temperature can be generated—an electric torch is an example—and the complicated apparatus necessary to obtain a low one, is striking. It is due essentially to the fact that when a substance is heated there is not only an increase in its energy, but also in the internal disorder among its particles. In illustration, there is complete disorder in a gas, whereas a substance cooled sufficiently to cause it to crystallise has its constituents arranged with a high degree of order. In all affairs, it is easier to decrease order than to increase it; it is highly improbable that shaking a tray containing a number of black and white balls would increase the regularity of their arrangement.

In the last example, the orderliness depends on one variable only; the possibility of attaining low temperatures depends on the fact that the orderliness among the molecules of real substances is governed by more than one variable. Consequently, orderliness introduced by the agency of a change in one variable, say, the volume, has its effect on the other variables, such as the temperature. From this point of view, a method commonly used for liquefying helium operates as follows: as the gas is compressed, the decrease in volume tends to increase the order, so that the disorder due to the heat motion has to increase; in other words, the temperature rises. The compressed gas is now cooled, which increases the total order again, and when it expands again, the resulting decrease in order due to volume must be compensated by an increase in the thermal orderliness, that is, by a fall in temperature.

In the practical application of this method, starting at moderate temperatures, the cooling effects obtained are quite small, owing largely to the overwhelming heat capacity of the container. At low temperatures this difficulty disappears, since, for example, at 12° K., 1 c.c. of helium gas at 100 atmospheres has the same heat capacity as 1 kgm. of copper.

Fig. 1 is a diagrammatic sketch of the actual apparatus used for liquefying helium and for reducing its temperature after liquefaction. The helium is contained in C, D being the liquid hydrogen bath, and the space S being evacuated. The vessel E can be filled with liquid helium through the tube T, and is of a shape suitable for applying a magnetic field to its contents. By lowering the pressure in E, the temperature can be brought down to about 2° K. The gas thermometer is represented by G.

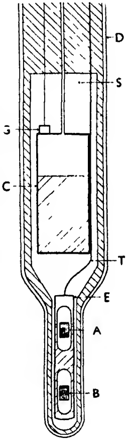

FIG. 1

At very low temperatures, the gas thermometer is impracticable and one other means of measuring temperatures is to utilise Curie's law, according to which the susceptibility of a paramagnetic substance is inversely proportional to its absolute temperature. This method has the great advantage that it increases in sensitivity as the temperature is lowered.

It has already been remarked that the lowest temperature reached by decreasing the temperature over liquid helium was about 0·7° K. No substantial progress is to be anticipated by this method, and we have to seek some other disordered systems than gases on which to operate. Such systems are to hand in the paramagnetic salts mentioned above. In them, there are elementary magnets which, owing to the thermal agitation, are directed at random. When a magnetic field is applied, the magnetic orderliness is increased, so that the thermal order decreases, that is, the temperature rises. If the substance is now cooled by contact with its surroundings, so as to increase the total order, and the field afterwards removed, order is transferred from the magnetic to the thermal mode, and the temperature falls again. This method was proposed by Debye and Giauque about ten years ago, and has been successfully used in recent years by Giauque, de Haas, and Kürti and Simon.

Iron ammonium alum, with a field of 14,000 gauss, gives by this method temperatures down

* Substance of a discourse delivered at the Royal Institution by Dr. F. Simon on Friday, February 1.

to 0·04° K, whilst with potassium chromium alum, and the large magnet of the Leyden laboratory, de Haas has reached 0 015° K.

Insulation at these temperatures is an easy matter, since radiation becomes negligible, whilst the vacuum round the substance is very high on account of the low temperature itself This is illustrated forcibly in the accompanying table, which shows the vapour pressures of helium (the gas with the highest vapour pressure) at various temperatures

Vapour Pressures of Helium

T (°K)	p (mm)
1 0	1 5 × $10^{[illegible]}$
0 7	3 2 × $10^{[illegible]}$
0 5	2 5 × $10^{[illegible]}$
0 3	7 × $10^{[illegible]}$
0 2	3 × $10^{[illegible]}$
0 1	3 × $10^{[illegible]}$
0·05	4 × $10^{[illegible]}$
0 03	6 × $10^{[illegible]}$

It is interesting to note that the temperatures obtained by the demagnetisation technique are below any found in Nature Even in inter-stellar space, radiation maintains a body at least 2° K above absolute zero

To examine the properties of other substances at these very low temperatures, a small pellet is made by mixing the substance to be examined with the paramagnetic salt By this means, several new supra-conductors have been discovered, though even at 0 05° K there are metals which do not show supra-conductivity Again, it immediately becomes evident if the specific heat of the admixed body is abnormal, and consequently gives an indication of any phenomena involving energy changes in this region

Finally, it must be emphasised that research in this low temperature region will be productive of fresh results, the effort to progress towards the absolute zero is not merely directed to the creation of fresh 'records' but to actual study of changes associated with energy increments of such magnitude that only in this region can they be observed

During the course of the lecture, the liquefaction of helium by the method explained above, of compressing the gas to 100 atmospheres, cooling it to 12° K with solid hydrogen and then allowing it to expand, was demonstrated The phenomenon of supra-conductivity in lead was shown at the temperature of the liquid helium, the current being produced and its existence shown by magnetic means

Norwich Meeting of the British Association

THE preliminary programme of the British Association meeting in Norwich on September 4–11 has now been issued The president, Prof W W Watts, announces the subject of his address as "Form, Drift, and Rhythm of the Continents" It would be difficult to conceive a title better capable of intriguing thoughtful laymen That continents possess form they will no doubt appreciate, but the ideas that continents should drift, and possess rhythm, ought to make them eager to learn It is to be hoped that it may be made easy for them to do so, for, to say truth, the Association in its endeavours in recent years to apply the advancement of science to the needs of its members, by reinforcing the voices of presidents through amplification, has been singularly ill-served as a rule

The building in which the address will be given is not yet settled, but the other rooms which will be in use by the Association are very conveniently placed In St. Andrew's Hall, formerly the fifteenth century church of a Dominican foundation, the business of the Reception Room will have a most imposing setting None of the section rooms is so much as half a mile from it, seven of them are immediately adjacent to it Norwich, once the visitor has learned the intricacies of its medieval streets, is unusually well provided with the type of accommodation demanded by the Association. As for the lodging of visiting members, the local committee, foreseeing some possibility of difficulty if members were left to make their own arrangements, offer to procure hotel or other accommodation for them, and indeed advise them not to communicate with hotels direct In this connexion it should be remembered that those who wish to combine a holiday with the meeting, and are not too closely tied by the business of the Association, have unusual opportunity to obtain pleasurable accommodation elsewhere than in the city The preliminary programme includes a long list of hotels (with prices) at Bacton, Caister, Cromer, Gorleston, Yarmouth, Holt, Lowestoft, Mundesley, Overstrand, Scole, Sheringham, West Runton and Wroxham, as well as in Norwich itself

The two customary evening discourses are announced That by Dr S J Davies will deal with Diesel engines in relation to coastwise shipping—a subject of topical interest (as it may be surprising to some to know), for the number of coastwise trading vessels which make their way up-river to Norwich has increased of late years. The other discourse will enter a field of still wider public interest. Dr C S Myers will speak on the help of psychology in the choice of a career

The programme announces a distinguished series of addresses by the sectional presidents Dr F. W Aston will speak in Section A on the story of isotopes. The address in Section B, by Prof. W. N Haworth, will introduce a discussion on the molecular structure of carbohydrates Prof G Hickling in the geological section will deal with some aspects of coal research Prof Balfour-Browne's address to Section D will be on the species problem The geographical section will follow its president, Prof F Debenham, to the polar regions Prof J G Smith will give the address in Section F on economic nationalism and foreign trade Mr J S Wilson's address to the engineers will be on the stability of structures In view of the regretted indisposition of Sir Cyril Fox, who was to have presided over Section H, the Association is fortunate indeed to have enlisted the services of Sir Arthur Smith Woodward, who, as it happens, has not previously presided over that Section, he will address it on recent progress in the study of early man. The address to the physiological section will be given by Prof P T. Herring on the pituitary body and the diencephalon, that to Section J (Psychology) by Dr Ll Wynn Jones on personality and age, and Section K (Botany) will hear Mr F T Brooks on some aspects of plant pathology Dr. A W Pickard-Cambridge's address to Section L (Education) will deal with education and freedom, and Dr J A Venn will speak to the agricultural section on the financial and economic results of State control in agriculture

It is well known that last year, in preparation for the Aberdeen meeting, the Council of the Association issued to the organising sectional committees a reasoned statement inviting their special attention to subjects bearing upon the relations between science and the welfare of the community Good effect was given to this request, and the results were favourable in respect of the additional public interest aroused by the meeting, while the daily and non-technical Press showed its appreciation of the choice of material provided for it by noticeably avoiding trivialities of its own creation. This year the Council reminded the committees of its previous memorandum, and brought these considerations to their notice, and already there is no lack of subjects of public interest in the Norwich programme. The Association is to make striking use of its mechanism for joint sectional meetings in bringing together engineers and psychologists to discuss the application of science to traffic problems Among other subjects which may be instanced in this connexion are those of noise and of lubrication in Section A; Section D will find itself near enough to the east coast to continue its practical interest in the herring, Section E will consider local town-planning and land utilisation. Section F has its usual array of important economic problems for discussion, and will also deal with the chronology of the world crisis, on which a committee of the Association will shortly publish a full report Hearing and aids to hearing will be considered by the Sections of Physiology (I) and Psychology (J), the place of psychology in the training of teachers by Sections J and L (Education) Section L will stage demonstrations illustrating physical education Section M (Agriculture) will base a discussion on the results of State control in agriculture upon the address of its president, Dr Venn

The local scientific interests of East Anglia are great and varied, as is very well known The geologists will be within reach of classic ground for glacial geology, and none will willingly miss the unusually valuable opportunity offered by a few days' tour of coastal and inland sections in Norfolk from Hunstanton to Cromer and Bacton, under the guidance of Prof P. G. H. Boswell, immediately before the meeting. Geologists and anthropologists together will inevitably discuss early man in East Anglia Botanists and agriculturists will interest themselves in land utilisation in the unique area of the Breck country, and East Anglia offers Section M an unusual variety of agricultural activities for its study The list of proposed excursions offers evidence of all these interests and more besides

In Section D (Zoology) there will be a commemoration of the centenary of the landing of Darwin in the Galapagos Islands (which falls a few days after the meeting) and the birth of the Darwinian hypothesis of the origin of species For the Association, as the custodian of Darwin's home at Downe, such an occasion is appropriate for remembrance Moreover, there is in this subject a throw-back, so to say, to the last meeting of the Association at Norwich, in 1868; for J. D. Hooker was the president of the Association then, and had much to say of Darwin, while in Section D the Rev M J Berkeley as president paid high tribute to him, though the voice of another clerical speaker was still uplifted in doubt, and associated the varieties of forms and species with "laws of nature inscrutable to us".

An evening reception by the Lord Mayor and Lady Mayoress (Mr. and Mrs P W Jewson) is announced to take place in the Castle Museum, and a statelier setting could scarcely be found elsewhere H M Lieutenant for Norfolk, Mr Russell J Colman, and Mrs Colman, will give a garden-party in the beautiful grounds of Crown Point.

The Royal Academy Exhibition

IT is always of interest to the student of natural science to see the impression which the objects of his study produce upon the artistic eye In respect of the range of nature study at the Royal Academy there is, however, a lamentable falling off in the matter of natural history With the exception of Mr Peter Scott's "Barnacle Geese in April" (210) there is scarcely anything of note, and the almost total absence of studies of big game, notably of the great carnivora, is very disappointing Yet the material is not lacking, for there is a remarkably fine exhibition of contemporary big game pictures in a neighbouring gallery, not "mere transcripts of the objects of Natural History" but true artistic compositions

Landscape, however, continues to be well represented There is a large number of pleasing pictures of English scenes in which architecture provides the focal feature amidst natural surroundings In the verdant landscape of the English plain a village church or a distant cathedral provides the artist with the massive and formal element which is lacking in a country from which the harder rocks are absent Again, in the hilly landscapes we find studies such as that by Mr Stanley Royle of "Mont Orgueil Castle, Jersey" (265), in which an architectural feature crowning an eminence develops the rocky forms to a pitch of steepness and a regularity of symmetry towards which Nature seems to strive but never quite attains Such examples of artistic treatment provide a valuable lesson for the scientific observer, for the artistic outlook is more in accordance with the natural faculties of the eye than that which results from classifying objects by their physical qualities

Among the most pleasing illustrations of the combination of architectural and natural features are those of bridges, with massive piers and arches spanning smoothly flowing water In "A Welsh Bridge" (189) by Mr Oliver Hall, the combination is enhanced by a rocky background which harmonises with the massive masonry This picture brings home very forcibly the need for scheduling such structures as ancient monuments for preservation, a lesson emphasised by Mr Charles Cundall's beautiful picture of a sad event, "The Demolition of Waterloo Bridge" (447)

In the illustration of the seasons, the Academy will greatly miss the late Mr J Farquharson's snow studies, of which, however, the present exhibition contains one small example, "In Glen Garry" (558)

In natural scenery the mode of illumination is scarcely less important than the features themselves, and we are indebted to Mr J Olsson for his beautiful study of moonlight—"Moonlit Surf Irish Coast" (297) There is also one very fine study made in the deepening darkness of the night, "Santa Maria della Salute, Venice" (532), the diploma work of Mr Richard Sickert

Mr A E Kelly's "Mount Sefton, New Zealand" (669) is one of the few pictures of the scenery of distant lands The want of studies of tropical scenery will be particularly felt by those who can recall the magnificent sunset effects in the equatorial belt

Among the portraits are several of personal interest to the scientific community Mr Francis Dodd's "The Lord Rutherford of Nelson, O M" (1207) is a strong drawing of a strong face Mrs Dodgson's drawing of the late Prof H H Turner (1253) renders admirably the quiet humour of the eyes beneath a thoughtful brow Mr Augustus John has portraits of Lord Conway of Allington (284) and Prof J C McLennan (288) Mr George Harcourt gives us a portrait of Colonel R E B Crompton (368) which reveals a vigorous personality, and in Sir James Crichton-Browne by Mr Oswald Birley (314) we see a fine rendering of calm and thoughtful reminiscence.

VAUGHAN CORNISH

The Royal Jubilee

ADDRESSES FROM THE ROYAL SOCIETIES OF LONDON AND EDINBURGH

IN addition to the messages of devotion and loyalty sent to the King from civic and governing authorities of the Empire at home and overseas, expressing congratulations to His Majesty upon the celebration of the silver jubilee of his accession, addresses were presented by a number of representative scientific societies The addresses submitted by the Royal Societies of London and Edinburgh are reprinted below.

TO THE KING'S MOST EXCELLENT MAJESTY

May it please Your Majesty,

We, Your loyal and dutiful subjects, the President, Council and Fellows of the Royal Society, humbly

beg leave to offer Your Majesty, the beloved patron of our Society, our respectful congratulations upon the completion of the twenty-fifth year of Your Majesty's reign.

The Royal Society of London since its foundation by King Charles the Second, has continued, under the illustrious patronage of each of Your Majesty's predecessors, to devote itself to the Promotion of Natural Knowledge, for which it was founded During Your Majesty's reign, the advance of Science has exercised an ever increasing influence on human thought, and, in its practical applications, on the material conditions of man's life and activities The Royal Society is proud to think that, with Your Majesty's continued patronage and approval, it has remained the centre for the recognition and promotion of the work of Your Majesty's subjects for the Advancement of Science throughout Your great Empire

The Royal Society accordingly claims the proud privilege of being permitted to offer this loyal tribute of esteem to Your Majesty, on behalf of men of Science, not only in the Mother Country, but also throughout the Empire. It is offered in the earnest hope that Your Majesty, with Her Most Gracious Majesty the Queen, may long continue to reign over Your devoted and loyal subjects

On behalf of the Council and Fellows of the Royal Society

TO THE KING'S MOST EXCELLENT MAJESTY

May it please Your Majesty,

We of the Royal Society of Edinburgh bring to Your Majesty and to Her Most Gracious Majesty the Queen our humble and hearty congratulations on the happy issue of the five-and-twenty years during which Your Majesty has ruled over a loyal and devoted people

These years of Your Majesty's reign mark a great epoch in History War has shaken the world and changed the lives and thoughts and circumstances of men But the devotion of the people to Your Majesty's Throne and Person has deepened and strengthened through all the changes and tumults of the age.

In this Royal Society the Natural and Physical Sciences are our daily occupation and task. Never have these Sciences flourished more than under Your Majesty's protection nor have they ever been more diligently applied to the service and advantage of mankind. Now for the first time in all the world men go their daily journeys above the clouds all nations and languages send speech and music through the air. and Your Majesty's voice is grown familiar in Your people's ears even to the ends of the earth throughout Your world-wide Empire and Dominions.

And that Your Majesty may long be spared in health and wealth to live and reign this Society will Ever Pray.

Obituary

SIR JOHN ROSE BRADFORD, BART, K.C.M.G., C.B., C.B.E., F.R.S.

THE death of Sir John Rose Bradford, on April 7, after some months of increasing disability, will be deeply regretted in many scientific circles Born in London on May 7, 1863, as the son of Abraham Rose Bradford, a naval surgeon, he was educated at University College School, University College, and University College Hospital, London, and had a brilliant career as a student, published physiological papers before he became qualified medically, and was specially interested in biology. His papers, however, were mainly physiological, and covered a wide field: on the electrical phenomena associated with secretion, on the innervation of the blood vessels; and particularly on the renal function, which he later extended to the subject of uræmia and disease. He probably hesitated about his life's work, whether strictly scientific work or medicine, for he was elected George Henry Lewes student in physiology in 1888, his predecessors being C S. Roy (1879), L C. Wooldridge (1882), and C. S. Sherrington (1884), and his immediate successors G N. Stewart and E. H Hankin jointly (1889). The decision was made when he accepted accelerated appointment as assistant physician to University College Hospital. His physiological researches gained him the fellowship in 1894 of the Royal Society, of which he was later secretary (1908–15). He thus, like his teacher, Sydney Ringer, combined the attitude of an all-round biologist with that of a practising physician

At the Royal College of Physicians of London, Sir John was elected a fellow in 1897, gave the Goulstonian lectures on the pathology of the kidneys (1904), the Croonian lectures on Bright's disease and its varieties (1920), the Lumleian lectures on the clinical experience of a physician during the campaign in France and Flanders in 1914–19, and the Harveian oration (1926) on the debt of medicine to the experimental method of Harvey, which may be read as supplementary, and as showing the other side of the shield, to the debt of science to medicine, the subject of Sir Archibald Garrod's Harveian oration of 1924.

Though a general physician, as shown in his Lumleian lectures, Sir John was best known for his work on kidney disease; he wrote standard articles in the second edition (1908) of the "System of Medicine" (Allbutt and Rolleston) on the general pathology of the renal functions and on nephritis, and a special form of nephritis became known as "Rose Bradford's kidneys". In the same "System" he also gave the accounts of diabetes insipidus and gout, the latter being a revision of the original article by Sir William Roberts, whose niece he married in 1899 He brought out a small work "Clinical Lectures on Nephritis" (1898), but, though he had plenty of material, he never, from the number of other activities, had time or perhaps the inclination

to write the treatise he could have done so well.

Among Sir John's many official appointments were that of professor-superintendent of the Brown Institution, Wandsworth, in his comparatively early life; member of the Mosley Commission (1904) to study educational methods in the United States of North America, for which he reported on the relations of hospitals to medical schools, clinical laboratories, and the teaching of medical pathology, senior medical adviser to the Colonial Office, the Medical Department of the Admiralty, and the Grocers' Company, chairman of University College Committee, senator of the University of London, president of the London and Counties Medical Protection Society, and a member or chairman of numerous committees Most conscientious, unobtrusively modest and endowed with a marvellous memory, he was an ideal chairman, and nowhere was this better shown than when president of the Royal College of Physicians of London (1926–31). It may well be said of him as a man that he earned "honour, love, obedience, troops of friends"

HUMPHRY ROLLESTON.

WE regret to announce the following deaths

Prof Auguste Marie, professor of microbiology in the Institut Pasteur, Paris, known for his work on rabies, cancer and tetanus, on March 30, aged seventy years

Mr J Milton Offord, president of the Quekett Microscopical Club, on May 4, aged seventy-four years

News and Views

The Royal Jubilee Broadcast

THE birth and development of modern radio broadcasting are not least among the items of progress in our civilisation, which have taken place during the twenty-five year period the termination of which was commemorated last Monday by the Royal Jubilee celebrations An excellent example of the present possibilities of broadcasting technique was provided on this occasion by the special programme from the B B C stations, which enabled listeners in all parts of the Empire to visualise the scene in London, including the crowds, decorations and the Royal procession, and to participate in the thanksgiving service held in St Paul's Cathedral The issue of the *Radio Times* of May 3 contains an illustrated description by the Outside Broadcast Director of the B B C of the arrangements which were made to carry out this programme Special microphones, with local control points, were erected at Temple Bar, Ludgate Circus and on the front of St Paul's Cathedral, from which was given a commentary on the Royal procession as it approached St Paul's, while in the Cathedral itself, seventeen microphone circuits were provided for the adequate handling of the thanksgiving service. The suitable mixing of the various portions of the programme received along the total of twenty-seven circuits was carried out by one man, who was situated in the temporary control room erected over one of the vestries in the north-east corner of the Cathedral. This control room was connected to Broadcasting House by six outgoing circuits, two of which were utilised by a foreign commentator

IT says much for the foresight with which the arrangements were made and for the thoroughness with which each person concerned carried out his work, that the programme was accomplished without a fault of any description. The whole network of interconnecting cables was entirely underground and was provided by Post Office engineers, at no point inside or outside St Paul's were there any visible signs of broadcasting As a broadcast of sound effects, interspersed with brief commentaries, the programme was satisfactory Much, however, was inevitably left to the imagination in order to visualise the glamour and splendour of the scene which was being portrayed Is it too much to hope that by the next occasion when a similar ceremony is to be broadcast, the sound picture will be supplemented by a vision programme, perhaps even in full natural colour ?

Association of British Chemical Manufacturers

JUBILEES are occasions of rejoicing and congratulation, but they provide us also with opportunities for taking stock both of our national resources and of the use we are making of them; so that when, after due examination and consideration, the celebrations are followed by renewed resolutions and by more fully informed and co-operative effort, they can fairly claim to have made a contribution of more than passing value to our national progress. Many organisations, national and sectional; political, ecclesiastical and industrial, philanthropic and learned societies, and indeed societies representing every phase of corporate life, will in 1935 be concerned to view with a critical eye their progress throughout the years of His Majesty's reign. In so far as they can show that their attempts to make the world a better place to live in have been honest, sensible and attended by a reasonable measure of success, they will receive a meed of applause; in so far as they discover how better to carry out the purposes for which they were brought into existence, they will equally merit the approval of sympathisers. The year 1935 is one in which chemical organisations in Great Britain will take decisions of exceptional significance They have long been considering how they can more adequately serve their science and more effectively promote its application for the benefit and prosperity of the community. Proposals which are now under consideration have been put forward with that end in view. One of the

organisations concerned, the Association of British Chemical Manufacturers, has recently published a brief survey of its work since its formation in 1916.

THE Association of British Chemical Manufacturers, which now has a membership roll of 117 firms representing a capital of more than £200,000,000, originated from the proposals of a committee representing the Chemical Society, the Society of Dyers and Colourists, and the Society of Chemical Industry, called at the suggestion of the first-named to consider the best methods of promoting co-operation between British chemical manufacturers Additional objects served by the Association are to provide British chemical industry with a medium for the expression of its views, to further technical organisation and promote industrial research, to facilitate the development and extension of British industries by keeping in touch with progress in chemical knowledge and practice; and to encourage closer co-operation between chemical manufacturers and the various universities and technical colleges These desirable objects have been steadily borne in mind by the Association, the annual reports of which show a long record of achievement, and it has been prominently associated with all movements of importance since its formation From its early days, the Association has maintained a service to keep members informed of the import and other statistics essential to their work, to keep them apprised of all directions in which now manufactures are needed, and yet at the same time to prevent useless overlapping by unnecessary duplication of effort The Association is closely concerned with questions of safety in chemical works, with matters arising out of the Import Duties Act, with negotiations leading to new commercial treaties with foreign countries, with the incidence of acts such as the Dyestuffs Act and the Patents and Designs Act, with transport and with exhibitions The monthly summary of information on chemical trade can be purchased by non-members.

Jubilee Exhibition at the Science Museum

To mark the occasion of His Majesty's Silver Jubilee, a pictorial exhibit illustrating the more outstanding inventions and conspicuous developments of the past twenty-five years has been arranged at the Science Museum, South Kensington This exhibition was opened to the public on May 1 and will remain on view during the whole of the month The main advances in the pure sciences, astronomy, mathematics, physics, chemistry, meteorology and geophysics are illustrated, together with their more important applications, for example, photographs are shown of the planet Pluto (which was discovered in 1930), modern methods of upper air investigations, radio-gramophones, 'talking pictures' equipment, infra-red photography and modern methods of prospecting Of special interest is the series of photographs showing the rapid advances which have recently been made in our knowledge of the constitution of the atom, and the structure of the atomic nucleus. Progress of chemical industry is shown to include many important developments such as the low-temperature carbonisation of coal, the manufacture of insulin, artificial silk and plastic products; while in the case of glass manufacture, reference is made to the improvements resulting from the introduction of machine processes and the influence on the glass industry of the widespread use of the motor-car Among other subjects represented may be mentioned the development of aircraft, ships, locomotives, motor-vehicles, steam turbines, oil and marine engines, while the advances in electrical power and communication are illustrated by modern electric power stations, automatic telephones, radio communication and television

Award of Kelvin Medal to Sir Ambrose Fleming

THE Kelvin Medal of the Institution of Civil Engineers, which is awarded triennially as a mark of distinction in engineering work or investigation of the kinds with which Lord Kelvin was especially identified, was presented to Sir Ambrose Fleming by Sir Kingsley Wood, Postmaster-General, on May 7 Referring to our dependence on the universities for the inception of new scientific methods and scientific knowledge, Sir Kingsley said that thanks are due to Sir Ambrose not only for his own contributions, but also for the inspiration he has given to generations of students, which have spread over the world in ever widening circles like the wireless waves themselves Sir Ambrose was one of those pioneers in the science of radio, who worked under both physical and financial difficulties, and yet succeeded in placing at our disposal a means of communication of thought sound and vision Broadcasting may well be one of the greatest factors in drawing together the nations of the world Sir Kingsley said that mass production in research produces results, but at a relatively higher cost than the research of inspired and gifted individuals, which has hitherto characterised the majority of the investigations carried out in Great Britain

Viruses and Heterogenesis

THE definition and nature of life have been favourite subjects for ancient and modern discussion Sir Henry Dale, armed with many recent exact data, stated in the Huxley Memorial Lecture on "Viruses and Heterogenesis", delivered at the Imperial College of Science on May 2 (London · Macmillan and Co, Ltd 1s net), the dilemma which confronts those who attempt to decide whether all the viruses which cause disease are self-propagating micro-organisms or whether some of them do not originate from the tissues of the host Admitting that their minute size is perhaps the most important obstacle to accepting the smallest viruses as frankly living, he pointed out that there is an unbroken series from a virus of about the same size as the smallest bacteria with a diameter of 750 mμ to the virus of poliomyelitis estimated at 10 mμ, which approaches the size of a protein molecule, the diameter of a molecule of egg-albumin has been calculated as 4·33 mμ (1 mμ = one millionth of a millimetre). The long category of viruses has several

characters in common, making it very difficult to draw an arbitrary line at a certain size as criterion for separating two classes of entirely different natures

SIR HENRY referred to Huxley's discussion of biogenesis and abiogenesis, and to the recurring claims for the origin of life from dead matter, including the 'spontaneous generation' of worms, maggots and bacteria, and the repeated victories of the advocates of biogenesis He stated his personal opinion that the similar claim that viruses have their origin by heterogenesis in the tissues of the host would in the future be disproved and that the doctrine that like breeds like would triumph in this field also Sir Henry emphasised the fact that viruses are obligatory parasites and suggested that the minute filterable particles are only a stage in the life of the infective agent, which might be able to reconstitute larger and more complete forms inhabiting the cells of the host where they cannot now be recognised or their size determined He propounded the view that our theoretical problem is not to determine the lowest limit of size compatible with the minimum required for a living reproductive cellular unit, but to determine what is the minimal portion of such a unit which might be adequate for its reconstitution under favourable conditions.

Royal Institution: Annual Meeting

MAY 1 was the day of the annual meeting at the Royal Institution, when the members received the report of their committee of visitors on the state of the Institution during the year 1934, and when the election of officers took place in accordance with the time honoured procedure The three scrutineers were sent to watch the three balloting glasses during the half-hour that the ballot must remain open, at the end of the time they marched out to the private room appointed for the counting of the votes; and in due course they returned, to report to the meeting the names of the officers, managers and visitors elected for the year 1935–36 The president is to be the Right Hon. Lord Eustace Percy, the treasurer, Sir Robert Robertson; the secretary, Major Charles E. S. Phillips, new managers are Prof E. N da C Andrade, Sir Frederick Berryman, Prof A Fowler, Sir Richard Paget, Prof. A O. Rankine, Dr G. C Simpson, Mr. W J Tennant and Mr James Whitehead. The visitors report testified to increased membership, to improved attendance at the lectures and to a year of varied activities in the Institution The accounts show a financial position which cannot but be gratifying to the members and to their treasurer, Sir Robert Robertson, who has had charge of the finances since 1929, one of the most eventful and at times anxious periods in the Institution's history. The report of the Davy Faraday Research Laboratory records valuable progress during the year in the researches, largely on the structure of organic molecules, directed by Sir William Bragg. In the unavoidable absence of the president, Lord Eustace Percy, the meeting was conducted by the honorary secretary, Major Phillips; and it was remarkable for the felicitous terms of a speech in which the thanks of the members were given to the president for his services during the past year by Sir James Crichton-Browne, of whom the evidence of *Who's Who*, that he is now in his ninety-fifth year, is difficult to credit.

Atomic Arrangement in Metals and Alloys

PROF W L BRAGG, in the twenty-fifth annual May Lecture before the Institute of Metals on May 8, dealt with the inner structure, or atomic arrangement, of metals and alloys In general, when one metal is alloyed into another a series of phases appears Metal A dissolves a certain amount of metal B with a gradual alteration in properties as the proportion of B increases At a certain composition, a limit is reached, and for greater amounts of metal B a new phase appears as separate crystals of quite different properties mixed with the first phase Regions of single and double phase alternate as the composition varies from pure A to pure B These phases are the nearest approach in an alloy system to the chemical compounds formed by combining elements. X ray analysis has shown that each phase has its own definite pattern, such as a cubical array with atoms at corners and centres, or at corners and centres of faces The pattern changes from phase to phase One of the most striking generalisations about alloy patterns to which X-ray analysis has led us is the empirical Hume-Rothery rule, which states that the ratio of free electrons to atoms in a structure is the same for alloys with the same pattern. H Jones has recently shown how the alloy pattern affects the binding energy of these free electrons, and so has given a reason for this rule Another point brought out by the X-ray analysis is that the method of arrangement of the atom amongst the positions of the phase pattern can be varied widely The phase pattern is an entity apart from the way the atoms are distributed, in marked contrast to ordinary chemical compounds The study of the movements of the atoms amongst the positions, as affected by heat treatment, can be made the basis of a very interesting theory; at high temperatures the atoms are shuffled up in a random way, while at low temperatures they sort themselves out into a regular alternation The importance of this work is that it provides a basis for the chemistry of compounds formed between metals.

A National Statistical Service

THE establishment in Great Britain of a special statistical council comprised of business men, bankers, economists and members of the general public charged with the task of instituting a National Statistical Service was recommended by Mr Roy Glenday in opening a discussion on "The Use and Misuse of Economic Statistics" before the Royal Statistical Society on April 16. This new body would not itself collect statistics, but would devote its energies to co-ordinating the statistical work now being performed by Government departments, private bodies and individuals. Mr. Glenday pointed out that international trade has reached a crisis in its fortunes

since the 'white' populations are rapidly approaching stagnation—that of Great Britain is actually on the eve of a decline—yet we have no means of measuring the industrial and commercial changes which this entails No organisation has been evolved to collect the statistics and other information which it is imperative to possess, and instead we are continuing to press forward with reorganisation schemes in housing, education and transport at home and to expand food and raw material supplies overseas as if world populations are destined to go on expanding at the old rate and with their age distribution unchanged The fundamental statistical facts and trends in regard to our economic life should become as much part of the common stock of ideas on which all act, as are certain of the fundamental facts of physics and chemistry

Economics of Progress

THE James Seth Memorial Lecture at the University of Edinburgh was delivered on April 26 by Mr Roy Glenday, economic adviser to the Federation of British Industries, who took as his subject "The Economic Consequences of Progress" There is a limit, he said, beyond which it is unhealthy to allow growth to proceed even in a community which takes special care not to overstep the frontiers of its own territory Conflict will still inevitably arise in the process of growing, under the pressure of congestion between the members of the different groups or subdivisions into which the community of necessity splits its territory and occupations No matter what may be the basic plan of subdivision adopted, there is a limit to the size of economic structure which can be erected on it with safety The United Kingdom, however, still possesses enormous resources, and the solution Mr Glenday favours is the one which accepts present tendencies as both reasonable and inevitable. They should be encouraged by promoting a flow of migrants from Great Britain, not for the purpose of developing the land and country-side of the Dominions and Colonies but to enlarge their industries and towns Given supplies of cheap capital, there are no insuperable obstacles to a redistribution of population between the over-populated Mother country and the under-populated Dominions overseas. This would be as much to their advantage as to ours In Canada, for example, the railways could serve a population three times its present size

Guide to National Collections

AMONG the numerous suggestions which have been put forward of means whereby the public might be stimulated to visit in greater numbers the museums and national collections in London, that of a general guide covering all the collections has been one of the most attractive It has been pointed out that few, outside those who are technically or professionally interested, know where to find exhibits which will illustrate subjects on which they desire to be better informed, while even among the learned and scientific public, not many could without hesitation state off-hand the range and purpose of each unit in the series A "Brief Guide to the National Museums and Galleries of London" (H M. Stationery Office, pp. 106. 6*d* net) has now been issued in accordance with a recommendation of the Standing Commission on Museums and Galleries in the hope, as expressed by Lord d'Abernon, the chairman, in a prefatory note, that "this guide, giving in compendious form the salient facts of interest concerning each of the Institutions, may stimulate public interest, both at home and abroad, in the unrivalled resources of the National Collections" It is not intended to supersede individual guides and handbooks, but to supplement them by giving briefly within a single cover information relating to the origin, purpose, range and arrangement of each, together with much useful and practical information, such as how to get there, time of opening and closing, charge for admission, if any, and the like Especially helpful is a series of street-maps, showing the approaches The information is clear, direct and comprehensive and there are some excellent illustrations Experience will show whether the information is given in a form which will attract those for whom it is intended Should the demand justify, it will be revised annually Copies may be obtained at H M Stationery Office sale branches or through any bookseller, as well as at the museums

University of London Buildings

MR T LL HUMBERSTONE sends us a copy of a letter he has sent to the Clerk of the London County Council relating to the provision of an open space on part of the site of the new buildings of the University of London at Bloomsbury He informs us that since his election as a member of the Holborn Borough Council in November last, he has found that an undertaking was given by the University to the Council and also to the London County Council that the University would "preserve a garden area with trees and grass equal in size to, but not necessarily identical in location with, that now existing in Torrington Square gardens". It appeared after inquiries made by Mr Humberstone that this undertaking was not carried out by the layout of the buildings Representations were therefore made, with the result that a new design and layout have been prepared, providing approximately an acre of additional open space in the form of three bays on the Malet Street frontage, giving this façade a crenelated form Mr Humberstone is the author of a valuable historical work on "University Reform in London" and contributed to NATURE of July 9, 1932, a long article on the development of the University and the design of the new Buildings.

British Oil from Coal

THE first train load of 100,000 gallons of oil made by low-temperature carbonisation from British coal went to the new plant of Imperial Chemical Industries, Ltd. at Billingham from the Barugh (Yorks) works of Low Temperature Carbonisation Ltd on April 26 The train, which was drawn by two locomotives, consisted of 34 tanks of 3,000 gallons each and weighed

nearly 1,000 tons gross. On arrival at Billingham the oil, which is made from coal by the coalite process, is being submitted to hydrogenation and converted into about 100,000 gallons of petrol This is the first time that a bulk consignment of oil obtained by low-temperature carbonisation has been treated by a hydrogenation plant in Great Britain Tests carried out by Imperial Chemical Industries, Ltd, and H M Fuel Research Board show that this oil is particularly suitable for conversion into petrol by hydrogenation, and the event constitutes a notable achievement in the history of the coal and coal oil industry in Great Britain

The B B.C Annual

THE *B.B C Annual* for 1935 (London B B C 2s 6d) is the successor to the *B B C Year Book* for 1934 This Year Book, after a fairly successful career, has been discontinued The first section of the *Annual* gives a history of the Corporation's programme policy for the last five years The second section is the Corporation's report to the listeners of Great Britain A report is also given of the activities of the Empire service We are told that the object is not merely to give a recital of past programmes remembered or forgotten, but to explain and make comments on them Old problems have to be reconsidered and new problems are always arising So a new section is started called the 'forum', which is to be a market place for the expression of ideas by authors, who are wholly free and solely responsible for what they write, and is not a pulpit for making pronouncements It contains some interesting articles discussing amongst other subjects international broadcasting, free speech, music and radio drama. There is also an excellent short obituary notice of the late Mr J H Whitley, who devoted himself during the last years of his life to guiding most successfully the progress of this great national corporation

Dorothy Temple Cross Research Fellowships

THE Dorothy Temple Cross research fellowships in tuberculosis for the academic year 1935-36 will shortly be awarded by the Medical Research Council, and applications should be lodged with the Council not later than June 1, 1935 The object of these fellowships is to give special opportunities for study and research to persons "intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms" Candidates must be British subjects The fellowships will preferably be awarded to candidates who wish to make their studies or inquiries outside the borders of Great Britain They will be awarded for one year as a rule, but in special cases may be renewed The value of the fellowships awarded will depend in each case upon the standing and qualifications of the candidate, but will not be less than £350 per annum, payable monthly in advance. Travelling and some incidental expenses will be paid in addition. It may also be possible to award a senior fellowship of considerably greater value to a specially well-qualified candidate wishing to undertake an intensive study of some particular problem of tuberculosis at a chosen centre of work in another country Further particulars and forms of application are obtainable from the Secretary, Medical Research Council, 38 Old Queen Street, Westminster, S W 1

Leaflets on Disease of Fruit Trees

THE Ministry of Agriculture has recently issued Collection No. 1 of Leaflets on Fungus and other Diseases of Fruit Trees, price 1s 6d net This collection contains a copy of each of the leaflets on the subject at present issued by the Ministry, and is bound up in portfolio form so that when a new leaflet or a revised edition of an old one is published an insertion or substitution can readily be made Sectional vol 1, which contained the same leaflets in a permanently bound form is, therefore, superseded, as it is hoped that the new arrangement will prove of greater convenience. Those who desire to receive a copy of each new or revised leaflet as it is issued, in order to keep their portfolio up to date, may do so on payment of a nominal annual registration fee. Full particulars concerning this matter may be obtained from the Secretary, Ministry of Agriculture and Fisheries, 10, Whitehall Place, London, S W 1.

Cultivation of Soft Fruits

OWING to the imposition of import duties, soft-fruit growers in Great Britain have been able to find a satisfactory market for home-grown fruit during the past two seasons. The issue of a second edition of Bulletin No 4, "Soft Fruits", by the Ministry of Agriculture (London. H M S O. 1s. net) will, therefore, be particularly welcomed as it will enable the grower to make the fullest use of his protected position. The principal fruits dealt with in the bulletin remain as before, namely, strawberries, gooseberries, currants, loganberries, raspberries, figs and melons, though the subject matter has been considerably revised Sections on the cultivation of blackberries and dewberries have, however, been included in the new edition, owing to their increasing popularity. The cultivation of nuts is now omitted, as it is hoped to issue fuller information on nut culture as a separate bulletin

New Zealand Scenery

THE active steps taken by the New Zealand Government to preserve the original scenery of the Dominion are noted in the report on scenery preservation for the year ending March 1934. During the year, more than thirty new reserves were announced. They varied in size from small historic sites to areas of several hundred acres, the largest being about 9,000 acres in the Canterbury district, where a great area of beech bush has been set aside The total area of scenic reserves in New Zealand is now about a thousand square miles, divided into about as many different parts. The Act of 1908 under which such area can be dedicated to public care has now been amended to allow of any landowner applying to

have his land declared a private reserve This will help to maintain the scenic amenities of New Zealand.

The North-East Passage

SINCE Baron A E Nordenskiöld in the *Vega* made the North-East Passage in 1878–79, other ships have followed the same route, but it was not until 1932 that the journey was made in one season. In that year Capt O J Schmidt took the ice-breaker *Sibiriakov* from Archangel to Vladivostok It is now reported by Science Service that in 1934 the ice-breaker *Theodor Lütke*, commanded by Capt Nikolaev, went from Vladivostok to Murmansk in eighty three days It should, however, be noted that heavy ice was encountered, and that the passage would have been impossible for a less powerful vessel These achievements hold out little prospect for an ordinary unprotected trading vessel making use of the route for through passages

Study of Malnutrition

A PUBLIC meeting, organised by the Committee against Malnutrition, will be held at the Conway Hall, Red Lion Square, London, W C 1, on Thursday, May 16, at 8 p m , to consider the health and nutrition of women and children in Great Britain The chair will be taken by Prof V H Mottram, and Miss Eleanor Rathbone, M P , Dr Janet Vaughan, and Prof Marrack will be among the speakers Tickets at 1s each can be obtained from the Honorary Secretary, Mr F le Gros Clark, 190 Eagle Street, Holborn, W C 1 The Committee against Malnutrition, which is a non-party organisation and has been in existence for a little more than a year, was established to obtain information respecting under nourishment among families of unemployed and low-paid workers, and to co-ordinate efforts towards securing adequate nourishment for all It publishes a bi-monthly bulletin, and organises propaganda on the subject The annual subscription is 5s

Announcements

THE King has been graciously pleased to command that the African Society shall henceforth be known as "The Royal African Society".

DR WALLACE RUDDELL AYKROYD has been appointed by the governing body of the Indian Research Fund Association to the post of director of nutritional research under that Association

A MEETING, followed by a discussion, will be held by the British Science Guild in association with the Engineers' Study Circle on Economics, on Thursday, May 16 at 5.30 p.m in the Lecture Theatre of the Institution of Civil Engineers, Great George Street, S W.1, when a report on schemes and proposals for economic and social reforms will be presented by Lieut - Col. J.V Delahaye. Tickets (for which there is no charge) are obtainable on application to the Secretary of the British Science Guild, 6 John Street, Adelphi, W C 2

THE North East Coast Institution of Engineers and Shipbuilders, Newcastle-on-Tyne, will celebrate the attainment of its jubilee by a series of meetings to be held on July 16–19, in Newcastle-on-Tyne. The celebrations will open with a reception at Armstrong College On July 17 there will be a meeting to confer honorary fellowships, after which three papers will be read dealing with developments in ship construction during the past fifty years On July 18 papers on marine engine construction, including turbines, reciprocating steam engines, boilers and heavy oil engines, and on recent progress in electrical and general engineering, are to be read, and on the following day Sir Westcott Abell will deliver a citizens' lecture on "Ships through the Ages".

WE regret that in the article on "Canadian Water Power Developments in 1934", in our issue of April 27, p 642, it was stated that the investment represented by the present development is estimated at 1,743,000 dollars This should read 1,743,000,000 dollars

"CATTLE IN THE TROPICS" is the title of a booklet by Prof Cecil Wood of the Imperial College of Tropical Agriculture, Trinidad (Government Printing Office, Port of Spain, 1934) It gives much useful information on the species and breeds of cattle suited to tropical conditions, their utilisation as draught animals and for meat and milk production, harnessing, feeding and general care, breeding and improvement Sections are also devoted to their health and the diseases which affect them, and to the organisation of the industry

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A professor of physiology in University College, Dundee (University of St Andrews) –The Secretary (May 17) A temporary assistant engineer in the Ministry of Transport—The Establishment Officer, Ministry of Transport, Whitehall Gardens, London, S W 1 (May 17) Chemists for the War Department chemist, Woolwich Arsenal –The Under-Secretary of State (C 5), The War Office, London, S W 1 (May 18) A secretary to the Advisory Council for Technical Education in South Wales and Monmouthshire—The Advisory Council, County Hall, Cardiff (May 18). A teacher of mechanical engineering and a teacher of electrical engineering in the Schools of Technology, Art and Commerce, Oxford—The Secretary for Education, Education Office, George Street, Oxford (May 20) An animal husbandry expert under the Imperial Council of Agricultural Research, India – The High Commissioner for India, General Department, India House, Aldwych, London, W C 2 (May 25) A lecturer in mathematics in the Royal Naval College, Greenwich—The Adviser on Education, Admiralty, Whitehall, S W 1 (May 31) An assistant professor of science in the Indian Institute of Science, Bangalore—The Director (June 1). An assistant inspector of ancient monuments for Wales —The Establishment Officer, H.M Office of Works, Westminster, London, S.W 1 (June 3) An inspector of agriculture in the Department of Agriculture and Forests, Sudan Government—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, London, S W.1 (June 10).

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P 794

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

Relation of the Posterior Lobe of the Pituitary Gland to Anæmia and to Blood Formation

IT has been shown (Dodds, Noble and Smith[1], Dodds and Noble[2]) that it is possible to prepare an extract of the posterior lobe of the pituitary gland which, when injected subcutaneously or intravenously into animals, will cause an intensive hæmorrhagic lesión of the acid-bearing area of the stomach, from which the animals usually recover completely. Chronic ulcers may also be produced

During the course of study of the biological properties of this extract, further interesting facts have been observed If rabbits be injected subcutaneously with 150 mgm of the acetone picric acid extract of the posterior lobe of the pituitary, or alternatively with 40 c c of standard B P pituitary extract, a number of them develop a definite severe macrocytic anæmia The following table shows the typical hæmatological picture produced by this treatment

Rabbit No 363 ♂ 2 0 kilo				
Time	W B C	R B C (Million)	Hæmoglobin gm per 100 c c	Reticulocytes
				Per cent
	10,400	6 15	13 9	0 50
	9,800	5 95	13 9	0 75
Injection	20 c c B P	Pituitrin s	ubcutaneously	
1 day	11,600	6 00	13 6	2 00
2 days	8,600	5 45	12 3	0 10
3 ,,	12,000	5 95	11 8	0 50
5 ,,	15,400	3 10	8 4	8 00
6 ,,	9,800	2 35	7 5	17 00
8 ,,	9,600	2 88	7 5	21 00
9 ,,	13,400	2 36	6 8	24 00
10 ,,	9,800	3·03	7 0	20 00
12 ,,	8,800	2 83	7 6	9 00

The anæmia appears quite suddenly on the fourth to fifth day, the red blood count frequently being as low as one million cells per c mm A marked leucocytosis, up to 50,000 white cells per c.mm., is often associated. The hæmoglobin falls proportionally less than the red blood count A reticulocyte response commences on the fifth to sixth day and usually continues for seven to eight, reaching a peak about the ninth day. Reticulocyte counts up to 50 per cent have been observed. Examination of the blood smear shows the red cells to be well filled with hæmoglobin. Anisocytosis is present to a marked degree. Many large macrocytes and an occasional microcyte are seen. Poikilocytosis is slight Nucleated red cells have been observed. Platelets appear normal Leucocytes are mainly of the multi-nuclear type.

A series of control experiments have shown that hæmorrhage occurring from gastric lesions is not sufficient to explain these changes. Also control extracts of other tissues have not given any response on injection. If the animal be killed there are definite changes in the spleen, such as hæmorrhagic infarcts. The bone-marrow appears to show signs of hyperplasia The secretion of bile is greatly increased, as shown by a visible gross excess in intestines and faeces

So far as we are aware, this is the first time these changes have been produced by an extract of a normal gland The interpretation of these results is at present obscure The possibility arises that the control of blood destruction by the reticulo-endothelial system may be vested outside the system itself and may reside in the posterior lobe of the pituitary gland The reticulocyte response may be secondary to the anæmia, or alternatively may be due to the effect of the extract of the posterior lobe of the pituitary on the stomach causing it to produce an excess of the intrinsic factor, which in its turn acts upon the bone-marrow Intensive investigations are being conducted into these points at the present time

We wish to thank Dr L E H Whitby for kindly examining our data and for his opinion on the blood picture

The Contractile Factors of the Chromosome Micelle

IN a recent article in these columns[1] and in a paper presented to the Royal Microscopical Society on February 20, 1935[2], I put forward a model of a chromosome as an aggregate of polypeptide protamine molecules in association with nucleic acid It is unfortunate that data of a physico-chemical nature by means of which this hypothesis can be tested and rendered more precise are at present very meagre. It is, therefore, specially important to make the fullest use of such facts as are available, and in particular of those relating to the variable geometrical configurations of chromosomes, which are of the highest degree of delicacy and reliability[3,4] These are of particular importance in view of the recent work on the giant chromosomes in the salivary glands of *Drosophila*, *Chironomus* and *Sciara*[5]. I have, therefore, undertaken a systematic survey of these data and wish, in this preliminary announcement, to direct the attention of cytologists to the various contractile factors which the chromosome micelle may be expected to possess.

(1) The intramolecular or intermolecular contractile factors which depend upon electrostatic (salt-forming) attractions between basic and acidic ionised groups, belonging to the same[6] or different molecules.

These factors have already proved important in the case of keratin[7].

(2) The intermolecular contractile factor due to a variation in the number of ionised groups belonging to single molecules. This factor, which has not yet made its appearance in the literature of protein chemistry, is nevertheless an obvious possibility. The number of ionised groups possessed by a nucleic acid molecule[8] varies considerably with pH. The chromosome micelle—a protamine nucleate aggregate[9]—will therefore be capable of strikingly different configurations for different pH values, the nearer the pH approaches to the isoelectric point of the protamine nucleate the greater being the degree of contraction. In view of the differential density of nucleic acid along the length of the chromosome, differential condensation (heteropycnosis)[4] is naturally to be expected. This type of contractile factor also offers a simple interpretation of the results lately obtained by Kuwada and Darlington with ammonia vapour and with acetic and nitric acid[3].

(3) The intramolecular contractile factor as exemplified by keratin[7]. In the case of keratin a contractile factor of 2 in particular has been attributed to intramolecular folds of the nature of linked pseudo diketo piperazine rings. Evidently there may be other and more considerable degrees of contraction if the rings in question are formed not by two consecutive amino acid residues but by a run of 3, 6, 7, 10, 11, . . ., $4n - 2$, $4n - 1$ residues. The first of these, yielding a contractile factor rather greater than 8/3, may be the explanation of the contractile factor of about 3 recently announced for myosin films[10]. I now suggest that the chromosome micelle, evidently less stable than myosin and considerably less stable than keratin, will prove capable of a grosser type of folding, which will yield a far higher factor than the 2 of hair and the 3 of myosin.

(4) The intramolecular contractile factors due to the sharing of an electron by the ketonic oxygen and the hydrogen atom belonging respectively to the carbon and nitrogen atoms in the backbone of a protamine molecule[11].

(5) The macroscopic 'twizzling' factor as exemplified by keratin fibres[12]. This contractile factor is of quite different type from the three preceding ones. It is 'macroscopic' in the sense that it is a property not of individual molecules but of the micelle as a whole.

α-Tracks in Presence of Strong γ-Radiation

IN investigations of nuclear transformations, it is sometimes desirable to be able to observe α-particles (or protons) in the presence of strong γ-radiation. This has already been successfully accomplished by means of an ionisation chamber connected up to a valve-amplifier and oscillograph (as in the investigations of Chadwick and Goldhaber[1] on the photo-disintegration of heavy hydrogen).

It may be of interest that, under suitable conditions, it is also possible to observe α-particles in the presence of strong γ-radiation by the Wilson cloud method. The accompanying photograph (Fig. 1) shows the tracks of α-particles from polonium deposited on the outside of the brass cylinder A, in the presence of γ-rays from a 25 mgm. emanation tube placed inside A.

FIG. 1

The best conditions appear to be obtained with hydrogen in the chamber, at an initial pressure of about 40 cm. mercury, and a high expansion ratio somewhat above 1.4. Under these conditions, about 60 per cent of the α-tracks observed in the absence of γ-radiation are still observed when a source of about 25 mgm. is placed in A. The conditions become rapidly worse if the strength of the source is increased much above 30 mgm. and this appears to be about the maximum unfiltered emanation source that can be placed inside the chamber without destroying the cloud tracks of α-particles.

About five hundred photographs were taken with the cylinder A covered with beryllium, and a 20–30 mgm. emanation source inside A, in order to investigate further the disintegration of beryllium by γ-rays, observed some time ago by Szilard and Chalmers[2]. No α-tracks were observed. Assuming that tracks of range R cm. in air are actually produced, this means that the cross-section for the photo-disintegration of a Be nucleus is less than about $5 \times 10^{-30} R^{-1}$ cm.^{2}

The Spectral Selective Photo-Electric Effect

ZENER has recently[1] discussed Fowler's theory[2] of the spectral selective photo-electric effect, and concludes that it is incapable of explaining the observed order of magnitude of the emitted current. Inasmuch as a direct calculation[3] of the photo-electric emission from a pure metal yields a spectral distribution curve

differing only slightly from typical experimental curves for selective emitters, except as regards order of magnitude, the author considers Zener is right in stressing this last point as the main feature to be explained by a successful theory. Nevertheless, Zener's objection is not sufficient to dispose of Fowler's theory.

Fowler suggested that the surface potential variation of a selective emitter would be ideally of the form shown (Fig 1), having an intermediate hollow between metal and vacuum; and he showed further that the boundary transmission coefficient for such a field would have a maximum for energies for which standing waves could form in the hollow Zener objects to this that such a boundary transmission coefficient would lower the emission in general, but leave it unaltered at the selective maximum The further objection could be raised, that since the transparency level would be in use for a relatively wide frequency range, the spectral sensitivity curve would show quite a broad selectivity band, instead of the observed sharp maximum.

FIG 1

Both these objections, however, depend upon the fallacious argument that the emission from a metal with such a boundary field will be obtained essentially by multiplying the emission from a simple barrier by the appropriate boundary transmission coefficient The fallacy is as follows If the Schrödinger equation is set up for an electron in the boundary field (Fig 1), and solved for bound states, it is found that for those energies for which standing waves could form in the hollow, the electron density is very strongly concentrated therein Electrons in these states behave very similarly to atomic electrons, and give a correspondingly large transition probability The result is that, in spite of the smallness of the boundary transmission coefficient, the emission is on the whole large, while a steep maximum occurs for the combination frequency between the critical states forming standing waves in the hollow Experimental spectral distribution curves thus seem to be well reproduced by the theory.

If Fowler's theory is to be criticised, it must be on account of the predicted normal velocity distribution function This has two maxima, corresponding to the states forming standing waves in the surface, and the relative position of the maxima depends upon the frequency of the incident light Clear experimental evidence on this point would be of the greatest interest

Details of the calculation will be published elsewhere

A Rapid Practical Method of Demagnetisation involving High Frequency*

THE impossibility of demagnetising loosely packed or unrestrained particles of such material as that described previously in these columns[1] and the difficulty in demagnetising some of the new magnet steels prompted experiments which have produced a rapid method for substantially complete demagnetisation of all ferromagnetic substances

In direct opposition to the generally recommended procedure of using slow reversals and slow reduction of magnetic fields, it has been found that very rapid reversals of the field polarity and rapid reduction of the field strength are much more effective for the demagnetisation of material with high coercive force, especially when in a state of fine division In fact, the partially reduced hæmatite powder described in the previous note may now be conveniently demagnetised for the first time

The condition for effective demagnetisation may be brought about inside a solenoid by passing a damped oscillating discharge, or a series of such discharges, through the solenoid windings An 'induction furnace' used with a 3-kva high-frequency converter operates in this way but furnishes much more power than necessary Economically operated units have been built in which a direct current passing through solenoid windings has been repeatedly interrupted by a rotary make-and-break switch, across the gap of which a condenser had been connected The current, the number of turns in the solenoid, and the capacity of the condenser were regulated so as to give practically instantaneous demagnetisation of a substance without undue loss of power, a sufficiently accurate balance of capacity against inductance being obtained when a spark rather than an arc was produced on breaking the circuit. The speed of the switch was sufficient to ensure at least one complete oscillatory discharge to take place while the material was passing through the solenoid

A logical explanation of the effectiveness of this method for treating powders may be furnished by the supposition that the rate of magnetic field reversal is greater than that to which the poles of the magnetic substance can conform, thus permitting the particles to be caught in a more favourable position for demagnetisation than if time were permitted for their orientation in the prevailing magnetic field The fleeting high peak amperage of the damped oscillations, and internal shocks caused by the effect of high-frequency discharge, may also be contributing factors

This new H F method is applicable to any case where demagnetisation is desired It has been of considerable assistance in the laboratory in conjunction with the determination of the magnetic properties of powders, it is recommended for use in routine laboratory testing of bars or rods of iron and steel, and it may prove to be almost indispensable when the new magnet steels with coercive forces of 500–900 or more are encountered. The method can also be adapted to the commercial removal of permanent magnetism from minerals to permit better separation in processes involving magnetic concentration of ores

A literature search following the observations

* Published by permission of the Director, U.S. Bureau of Mines. (Not subject to copyright)

recorded above has revealed the fact that although a demagnetising effect by damped, oscillating, H F magnetic fields was noted by Henry and afterwards studied by Rayleigh, Rutherford, Marconi and others, none of the investigators seems to have realised the relation of this theoretical work to practical demagnetisation.

Variations in Interference Colours on Copper and Steel

THE high values of the refractive index of copper and iron make it probable that only slight changes of colour would be observed on varying the angle of incidence of the light. With burnished metal surfaces, changes of larger magnitude than expected (giving $\mu = 2 \cdot 4$ for copper oxide and $\mu = 1 \cdot 8$ for iron oxide) were observed with angles of incidence up to 78°, together with strong scattering of the complimentary colours At larger angles of incidence general reflection predominated, and all colour vanished except a slight effect due apparently to the metal itself

Some curious results were observed on strips of metal cleaned with fine emery paper The direction of the scratches was parallel to the length of the strip, and in the direction of increasing thickness of the oxide film. At angles of incidence varying from 70° to 80°, the change in the second order colours was marked in the direction of the scratches However, no change whatever (except increase in the generally reflected light) could be observed when the illumination was perpendicular to the lines of the scratches

In this case the strips were mounted on a spectrometer table and the telescope replaced by a microscope It then appeared that the colour of each filament remained unaltered, but that reflection occurred along a different line as the angle of incidence increased. Thus though the angle of incidence on the plane of the metal surface had varied widely, the angle of reflection from the coloured filaments in the surface had varied but slightly.

We wish to thank Abdel Hamid Effendi for the care he has taken in preparing the metal strips.

Rationalisation of Scientific Publication

THE Publication Committee of the Society of Public Analysts and Other Analytical Chemists has discussed a reference (p. 358) in a leading article in NATURE of March 9 to the abstracts published by the Society in its journal, and I am instructed by the Committee to direct your attention to inaccuracies in the strictures contained in that article

It is not true, as the article states, that the abstracts in *The Analyst* are merely later duplications or variations of abstracts already published by the Bureau of Chemical Abstracts. On the contrary, they are made directly from the original papers, and are frequently published before the abstracts issued by the Bureau These points, however, are of minor significance as compared with the character of the abstracts themselves, which are constructed on completely different principles from those adopted by the Bureau In the first place, all abstracts in *The Analyst* are given with sufficient detail to enable an analyst to try the method in his laboratory without having first to refer to the original paper Secondly, every abstract is minutely scrutinised, first by a specialist in the subject, and then by the Publication Committee, and if the method is found to be unsound, or to be wanting in novelty, the abstract describing it is not published

The principle adopted by the Bureau of Chemical Abstracts is different from this Its object is to give the gist of the paper abstracted, leaving the reader to refer to the original paper if he wishes to obtain working details of any method Doubtless this method of presenting abstracts saves space, but it cannot be claimed that it gives detailed working accounts of methods or affords any guidance to an analyst

This Society is always willing to co operate with other chemical societies, but attacks showing so little understanding of the objects and needs of a particular society will not tend to promote co-operation

C. AINSWORTH MITCHELL
(Secretary and Editor).

Society of Public Analysts
March 29

MR. MITCHELL'S letter in itself fully substantiates the statements made in the article I do not think he is entitled to say that the article is in any way inaccurate The substance of the charge is that the abstracts provided by the Society of Public Analysts in no way break fresh ground, they merely duplicate the effort which is expended by the British Chemical Abstracts, for example Mr Mitchell's letter shows clearly that the failure of the Society of Public Analysts to co-operate with the Bureau is due, first to a radical misconception as to what an abstract should provide, and second to the narrow specialist outlook which so largely frustrates efforts at co-operation

With regard to the first point, it cannot be maintained that an abstract should provide the full working details required If, as Mr Mitchell appears to contend, an abstract is insufficient for the purpose of his Society, he is advocating essentially a policy of reprinting published information in whole or in part This is in itself a lamentable source of duplicated effort and expenditure in the profession of chemistry, due, as Mr. Mitchell's letter shows, to the specialist's insistence in putting sectional needs before the general interest.

The reference to the Society of Public Analysts, however, was only made by way of illustrating a point in the article, which covers a great deal of ground It would not have been in keeping with the spirit of the article to have elaborated the point, even had there been any wish to do so

THE WRITER OF THE ARTICLE.

Sense-Organs in *Malacobdella*

WHILE examining living specimens of *Malacobdella grossa*, Müll., under a binocular dissecting microscope (the specimen being extended under a glass slide in sea-water in the usual manner), I noticed a pair of minute structures on the head, which, so far as I can trace, do not correspond to anything previously described in this species. Fig. 1, drawn from a living specimen, shows these organs anterior to the cerebral ganglia, which send a small nerve in their direction They have the appearance of small pits on the dorsal surface, suggestive of sense-organs They are unpigmented.

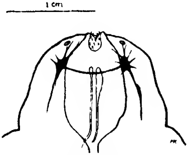

FIG 1 Head of *Malacobdella grossa*, drawn from life

I have examined serial sections of a specimen in which these 'organs' were seen during life, but so far have failed to find them, they have, however, been observed on several living specimens They are more conspicuous in large specimens If they are sense-organs, the fact is of some interest, since, except for the neuro-epithelial cells, *Malacobdella* has been supposed to be entirely devoid of these[1,2] A cephalic slit is present in most Nemerteans in a variety of forms, and a reduced cephalic slit might well present the appearance shown In some Nemerteans the cephalic slits are more superficial depressions; and if, as a result of the semi parasitic habit, these became reduced in *Malacobdella* to a vestige, they might be difficult to trace in preserved specimens, though visible during life.

The specimens were obtained in *Pholas* from the collecting ground known as 'Black Rocks', on the Anglesey shore at the eastern end of the Menai Straits. I can confirm the remarks of Gering[3] that the dimensions of *M. grossa* usually given are an understatement Living specimens measuring 45 mm. long in a state of moderate extension have been obtained here, whereas the largest Kiel specimen observed by Riepen was 22 mm. in length, and the largest Iceland specimen 30 mm. Blanchard[4] records a maximum length of 40 mm. The frequency here is also high, practically 100 per cent of specimens of *Pholas* being infected, as compared with less than 60 per cent infection recorded by Riepen for the host *Cyprina* at Kiel.

My thanks are due to Dr. Stiasny Wijnhoff for advice and assistance with the literature.

Discriminative Ability of a Parasitoid

IT has recently been demonstrated[1] that *Trichogramma evanescens* and certain other parasitoids are able to distinguish between healthy hosts and those already parasitised. Hearing cannot enter; sight and touch have been ruled out, and it appears that the sense used is that of smell

The discriminative ability is much finer than was supposed, as shown by the following experiment A *Trichogramma* female was allowed to walk upon and to examine a number of host eggs, but not to parasitise them The parasite was then removed and an equal number of clean hosts placed alternately among the others A second parasite now introduced avoided the hosts that had been visited by the first, as though they had already been parasitised The experiment has been performed several times, and there can be no doubt that *Trichogramma* females are able to distinguish clean hosts from those that have previously been merely walked upon by another female of their species, and that they avoid attacking the latter They seem also to be able to distinguish hosts on which they themselves have walked from those which have been visited by another individual.

One of us (J L) is now working on the application of this result to the spatial distribution of *Trichogramma*, and has evidence that the parasites are aware when they are moving over a surface previously walked upon by another parasite

This result renders intelligible a previous observation[1] on *Collyria calcitrator* and *Ibalia leucospoides*. Both of these parasitoids attack hosts which are buried in plant tissues and are therefore not available for examination Yet they tend to avoid superparasitism Possibly in these cases, too, the parasites are able to detect, on the surface of the wheat or of the wood, chemical traces indicating that another of their species has been there before them.

Apus cancriformis in Great Britain

Apus cancriformis has been so rarely recorded in Great Britain that it is of interest to report its occurrence in 1934. Some dried mud was collected from a pond in the New Forest district for the purpose of rearing *Chirocephalus diaphanus*, which was known to occur there. Distilled water was added to the mud on August 9, 1934, and larvæ were first noticed on August 12. These larvæ proved, on examination, to be those of *Apus cancriformis*, and not of the expected *Chirocephalus* Development proceeded, but many died. One individual measuring about 6 mm. across the carapace and 12 mm. from the anterior margin of the head to the base of the caudal furca was preserved on September 29 Another was exhibited alive at the Linnean Society's reception in October last.

Chemistry of Œstrogenic Substances

WE wish to make the following comments on the communication by E Friedmann in NATURE of April 20 (p 622) under the above title :—

(1) Dr. Friedmann apparently believes that the œstrogenic activity of synthetic compounds was first observed by Blum Bergmann[1], and afterwards verified by Cook, Dodds and Hewett[2] with compounds of analogous structure The reverse is, of course, the actual sequence of events, as is shown by the reference to our original publication in the paper of O Blum-Bergmann, wrongly quoted by Dr Friedmann as O Blum and E Bergmann.

(2) If Dr Friedmann had read our detailed publication[3] as well as our preliminary communication[1], he would have realised that the generalisation which he now makes regarding the molecular conditions necessary for œstrogenic activity does not accord with the facts For example, our series of diols derived from 9 · 10-dihydro-1 2 5 6-dibenzanthracene contains inactive members as well as compounds having an extremely high order of œstrogenic activity Yet if Friedmann's generalisation were true they should all be active Moreover, we have reported the œstrogenic activity of certain hydrocarbons, which, of course, cannot conform to any rule concerning the relative positions of an aromatic ring and the carbonyl or hydroxyl group. In addition, we observed activity with ergosterol and calciferol, which contain no aromatic or analogous furane ring In any event, the large doses of 1-keto-1 . 2 · 3 4-tetrahydrophenanthrene necessary to produce œstrus (50–100 mgm in rats) preclude any far-reaching deductions from the inactivity of the isomeric 4-keto compound in similar doses If, for example, the 1-keto compound had given positive results with doses of 0 1 mgm., and the 4-keto compound negative results with 100 mgm., there would have been more adequate basis for generalisation

Our experiments (in collaboration with Mr W Lawson) on the biological effects of diols prepared by the action of Grignard reagents on various quinones continue to yield results of interest, which will be fully reported when they are complete

Refractive Index of Heavy Hydrogen

IN the course of the recovery of some heavy water residues by electrolysis, the gas (D_2) was passed after purification through one side of the double tube (75 cm. in length) of a Rayleigh gas interferometer, while hydrogen gas produced by electrolysis of ordinary water and similarly treated was passed through the other side. A final steady shift of 24 drum divisions of the compensating plate was required to compensate for the difference of refractive index of the two gases This is equivalent to 1·68 fringes of the mercury line $\lambda = 5461$, and hence the difference of refractive index of ordinary and heavy hydrogen in the visible region is $(123 \pm 2) \times 10^{-8}$ at 760 mm, ordinary hydrogen being the greater The gas passed when the final reading was observed was burnt and collected separately, and proved to be within 0 1 of 100 per cent heavy hydrogen (D_2)

Deuterium Content of Naturally Occurring Water

THE deuterium content of naturally occurring water has so far been determined by two methods—from the mass spectrogram of the hydrogen derived from it; and from the specific gravity of deuterium-free water The former method[1] gave for the abundance ratio H/D the value 5000 ± 500, while two discrepant values[2,3] have been obtained by the latter, namely 9000 and 5750 ± 250

In order to clear up this discrepancy, we have measured the specific gravity increase caused by electrolysing tap water (+2 per cent caustic soda) This method presupposes a knowledge of the separation coefficient α, and is only susceptible of accuracy if α is not too low and varies between fairly narrow limits Experiments using water of known deuterium content had shown that for iron cathodes, α (corrected for evaporation) has an unusually high value; in seven experiments α had the extreme values of 8 65 and 11 0

In three separate experiments, 240 c c of tap-water were reduced to 20 c c by electrolysis with iron cathodes and the increase in specific gravity measured Taking $\alpha = 11\ 0$, the values obtained for the ratio H/D were 6640, 6390 and 6230 respectively, while for $\alpha = 8\ 65$ the corresponding values were 6230, 5980 and 5840, giving for the most probable value H/D = 6220 ± 300.

This is in agreement with the value 5750 ± 250 obtained by Johnston His result and ours, taken together, suggest that the mass spectrographic value is slightly too low, and are irreconcilable with the value of 9000

Philosophical Interpretation of Science

I HESITATE to reply to Prof H Levy's letter in NATURE of April 20 because the questions raised are matter for arm-chairs and midnight oil rather than correspondence. Some comment, however, must be made, so, leaving the justification of my own philosophical outlook for a more convenient occasion, I will simply refer briefly to the charge that I am representing my viewpoint as "a necessary consequence of scientific discovery".

I can only say that I do consider it a necessary consequence of scientific discovery That, of course, does not prevent me from believing that others hold

different opinions it simply leads me to think that they are mistaken. Frankly, I cannot conceive a better reason for holding an opinion than the belief that it is true It may be, however, that Prof Levy intended to charge me with trying to propagate my opinions among the uninitiated by disguising them as scientific facts. If so, I must say that the reader who could mistake the passage he quotes for anything but an attempt to interpret scientific procedure or who could regard any such interpretation as established truth, must be more uninitiated than one imagines readers of NATURE to be Surely one cannot be expected to encumber every sentence with "in my opinion" or "it seems to me" or "I think that", when it is obvious that the matter dealt with belongs to the world of opinion and not to that of fact But Prof Levy does seem a little confused about vital distinctions, for he refers to my interpretation as "itself surely an experience", and asks whether I am not compelled to refuse my philosophy any status in the external world Since he regards interpretation as experience, he has not begun to understand what I have been trying to say, and it certainly never occurred to me to claim that the external world contained philosophies

It may not be superfluous to add that since the review from which Prof Levy quotes was specifically concerned with the fact that one very eminent scientific man, whose insight I thought I acknowledged clearly enough, did not share my interpretation, an acute reader might have suspected that that interpretation was not indisputable On the other hand, out of a multitude of scientific men who could be quoted in support thereof, I select for want of space, only two, 'tolerably known in the revolution'. In "Atomic Theory and the Description of Nature" (p. 1), Bohr writes "The task of science is both to extend the range of our experience and to reduce it to order" In "The Meaning of Relativity" (p 1), Einstein writes "The object of all science, whether natural science or psychology, is to co ordinate our experiences and to bring them into a logical system" Neither writer explains that he is merely expressing an opinion, or indeed shows any awareness of the "very many men of science" whose views Prof Levy summarises

Points from Foregoing Letters

INJECTIONS of an extract of the posterior lobe of the pituitary gland produce notable changes in the blood of rabbits, leading to anæmia, according to Prof E. C Dodds and Mr R L Noble The red blood cells show abnormal inequality in size (anisocytosis), some being very large (macrocytes), others of irregular shape (poikilocytes) or having a network pattern (reticulocytes). The spleen shows wedge-shaped areas (infarcts) due to hæmorrhage From these changes the authors infer that the control of blood destruction may reside in the posterior lobe of the pituitary.

Chromosomes show great variation in size and shape Dr D M Wrinch discusses some of the factors that may give the constituent micelle of the chromosome the power to contract and change its shape Among these factors are the attraction between basic and acidic groups, the variation of the number of such groups within the molecule due to changes in the acidity-alkalinity of the medium (pH), the folding due to molecular linkage, as in keratin, etc

Mr D. Cameron discusses the best conditions under which tracks of α-particles can be observed in the presence of strong γ-rays during processes of dis integration, and shows how to determine the cross-sections for the disintegration of the beryllium nucleus by quanta of action

The liberation of electrons by light, a phenomenon of great importance in television, etc, shows in certain instances a strong narrow maximum as the wave-length of light is changed Prof Fowler has explained this selective effect as due to surface conditions, the original metal being covered with an electro-negative layer a few molecules thick and then again with a mono-molecular positive layer This view has been opposed by Zener, Mr. K. Mitchell now claims that Zener's objections are not valid, and that Fowler's theory can explain the observed facts both qualitatively and quantitatively He also shows that the theory leads to a peculiar form for the normal velocity distribution of electrons from a selective emitter, and appeals for experimental evidence on this point

Mr C. W Davis shows how, by means of high-frequency damped oscillations, materials of high coercive force can be demagnetised The method should be useful in the determination of magnetic properties of powders, the testing of iron and steel bars, in processes involving magnetic separation of ores, etc

The colour-changes of burnished surfaces of copper and steel seen at different angles are greater than expected from the refractive indices of their oxide films, according to Prof F H Constable and Messrs M Nazif and H. Eldin The authors also describe colour effects due to scratches on strips of these metals cleaned with fine emery paper

Dr L H Jackson submits a diagram and describes a pair of minute structures suggestive of sense organs on the head of *Malacobdella grossa*, a leech-like worm parasitic upon molluscs such as the chalk-boring piddock (*Pholas*)

The parasite insect *Trichogramma evanescens* shows greater ability than hitherto suspected in distinguishing between healthy egg-hosts and those already infected; Dr G Salt and Miss J Laing believe that the sense used in discrimination is that of smell

The synthesis of compounds having some of the properties of the natural sex hormone has lately attracted much attention Profs. J W. Cook and E. C Dodds dispute Dr Friedmann's views concerning the relation between œstrogenic activity and molecular structure as recently set forth in these columns.

Heavy water is rapidly becoming a commercial product and the proportion in which it is present in ordinary water is therefore important From the increase in specific gravity following upon an electrolysis of tap water, Messrs. A J. Edwards, R. P. Bell and J. H Wolfenden calculate this proportion to be one part in 6,000, as against one part in 9,000 previously deduced from mass-spectrographic data.

Research Items

The Ovingdean Skull. This remarkable trephined skull—a deformation, of which only two other examples of prehistoric date are known from Great Britain is described by Dr T Wilson Parry and Miss M L Tildesley in *Man* of April The skull was trawled from the sea about three quarters of a mile from the Sussex coast on January 12, 1935 It belonged to a man about sixty years of age, and its surface and texture denote that it had been interred It is not complete At the fore part of both parietals, an inch from the middle line on either side, are two well-defined perforations That on the right side is almost circular and measures $1\frac{3}{16}$ in by $1\frac{1}{4}$ in That on the left is roughly rhomboidal, the long diameter being $1\frac{1}{4}$ inches and the antero posterior $\frac{13}{16}$ in The method of trephining employed was that of scraping the bone with a flint flake so as to produce a funnel-shaped hole with sides sloping downwards and inwards towards the lumen, a method followed in the third, or Carnac, phase of the neolithic The operation was performed during life, as the bone shows a slight attempt at reparation A severe septic periostitis followed, which must have lasted about six weeks Miss Tildesley's examination indicates that there is nothing in the type of the skull to indicate its date Similar shapes occur among the Coldrum skulls, but also elsewhere Maximum breadth alone can be estimated The fragment is 143 mm broad and it is unlikely that the original maximum breadth was more than a millimetre or two more This lies half way between the greatest average found in the Beaker folk and the lowest found among the neolithic The bone is hard, suggesting mineralisation, and light grey in colour The circumstances suggest a cliff burial, which had fallen into the sea, but its colour and consistency are not the same as other bones from the chalk At the same time, it is not of an appearance which would suggest that it had come from a submerged neolithic forest bed The only clue to date is the trephining

Initiation in Southern Nigeria. An account of certain aspects of the *Otu* system of the Isa sub-tribes of the Edo people of Southern Nigeria by Mr. H L M Butcher (*Africa*, 8, 2) indicates the importance of this organisation, which in some respects resembles an 'age grade', in others a caste system, in the social system of the people under the Oba of Benin As a democratic institution it developed most characteristically in remoter districts where the people were less subject to the power and influence of the Oba Development, however, was not uniform, and local isolation has produced a number of variants In some the importance of the passage from grade to grade is ignored Members of the lowest grades in all groups alike are called 'sweepers of the streets', and consist of all youths who are able to do any work They perform all communal tasks, such as hewing wood, drawing water, etc Next are the 'adults' who are in the prime of their strength, and mostly have homes and families They do such work as may be beyond the power of the youths The senior members only fight in the serious wars, the minor raids being left to the younger men. Though they have no right to speak in the council, their numbers lend weight to their ideas. Above them are the 'junior elders', heads of families, seniors in the small divisions of the villages, who in most cases have performed a ceremony to free themselves from communal labour, but are not yet members of the council Finally, there are the 'elders', the repositories of justice and custom, at whose head is the senior elder His is the final word in the council, and usually he serves the ancestral ju-ju In most groups he is the administrative, as well as the religious, head of the community With the Otu are associated two classes of ceremony, the first is a 'qualification' ceremony and the second the group of ceremonies by which promotion is gained within the Otu

Rats and Mice of the Pacific Islands. Of the five forms of rats and mice found by the Whitney South Sea Expedition in the Pacific Islands, four are ship-borne, and have a world wide distribution, the black rat, the Alexandrine rat, the brown or 'Norwegian' rat and the house mouse (G H H Tate, *Bull Amer Mus Nat Hist*, 68, 145, 1935) These were probably introduced before the advent of white men, and the distinction between their arrival and that of the species regarded as the only true colonist of the Islands, *Rattus exulans*, is only a matter of degree, for the latter also owes most of its spread to mankind The native rats belong to the *concolor* group of Malaysia, but none of the island members of the group is identical with any living mainland species or with the forms found in Borneo, the Philippines, Celebes or New Guinea They tend to be larger than mainland forms, and on some of the islands show slight anatomical modifications Since all the rats and mice have been transported by man they must have followed his colonisation tracks, but this is not obvious from their present distribution since they show no diminution in number of forms from west to east Probably the original course of distribution from the mainland was by way of Borneo and the Philippines via the Caroline Islands, rather than through New Guinea and the Solomon Islands

Newfoundland Fisheries In the Reports of the Newfoundland Fishery Research Commission, vol 2, No 2 (Annual Report for 1933, recently published), good progress in all directions is shown Besides the technical research into the dried codfish industry and the nutritive value of the Atlantic salmon, the hydrographical and biological investigations are of special interest There are now available for comparison complete data for both spring and autumn seasons in 1932 and 1933 and partial data for the autumn of 1931 In the last report (vol 2, No 1) it was stated that, compared with the conditions in the autumn of 1931, there was in 1932 a much larger influx of arctic water into the Newfoundland area and simultaneously a stronger and opposite influx of salter water from the Atlantic occurring in the deeper water layers over the Banks These conditions led to the production of a large body of 'mixed' water suitable for the multiplication of marine forms of life, so that the season on the Banks and the coasts sharing 'Banks' conditions was a good one for the fishery, there being a marked increase in the plankton In the present report it is shown that this increase continued to a maximum point during the summer of 1933, but that in the autumn there was a sharp decline, apparently coinciding with a marked diminution in the general influx

of arctic water. In 1933 no salps were taken, indicating that Atlantic water, comparatively unmixed with water from other sources, did not invade the area; this is in accordance with the absence of high salinity water. The Copelata form a valuable guide to presence or absence of squid, the movements of which towards the coast of Newfoundland have in the two previous years followed the trend of *Oiko pleura dioica*, and the marked increase of the cold water *O. vanhöffeni* may perhaps always (as in 1933) precede a failure of the squid fishery for bait.

An Ancient Egg. The expedition to Texas, sent out by the Harvard University Museum, has discovered the world's oldest egg (Science Service, Washington, D.C.). It is the egg of a dinosaur which lived on the shores of a great inland sea during Permian times, and if the famous dinosaur eggs from the Desert of Gobi may be put at 100,000,000 years old, the age of this new discovery must be of the order of 225 millions of years. The egg, three inches long and rusty in colour, is unhatched and little distorted by the process of fossilisation. Although it cannot be definitely associated with any particular animal, it is believed to be the egg of a large lizard-like reptile, *Ophiacodon*, measuring about six feet from snout to tip of tail, and part of a skeleton of this creature was found near the egg.

Germination of Lime Seed. A very full study of the factors involved in securing prompt and abundant germination of the seeds of the lime is reported upon by J. Nelson Spaeth in Memoir 169 of the Cornell University Agricultural Experiment Station. His conclusion is that the pericarp is not important in delaying germination, but must be removed in order to treat the seed coat. Its removal is difficult because it is tough and leathery whilst the seed coat is hard and brittle. Seeds may be extracted by partially digesting the pericarp with concentrated nitric acid. Delay in germination is due to the impermeability of the seed coat; the water excluding property depends apparently upon the compactness of the cellulose in the outer part of the palisade tissue of the seed coat, and treatment with concentrated sulphuric acid for 10–30 minutes renders the seed coat permeable without injuring the embryo within. In view of the factor causing impermeability, the important result follows that air-dry storage, which dries this impermeable cellulose layer, increases this impermeability, and as a result air dried seeds after several years storage will remain impermeable to water for some years when placed in stratification.

A Fungus Disease of Liverworts. The *Gardens' Bulletin* of the Straits Settlements of January 26 contains an account of a new species of fungus, *Nectria egens*, parasitic upon a liverwort, *Leptolejeunia corynephora*. Mr. E. J. H. Corner is the author of the paper, and shows that the fungus is a superficial parasite the hyphæ of which ramify in the grooves between the convex cell-walls on the surface of the liverwort thallus. Food is absorbed through hyphopodia, and the host is not visibly inconvenienced by the parasite. Several other species of *Nectria* are known to attack bryophytes. Characters of the new species are given by a Latin diagnosis, and Mr. Corner has compared it with another bryophilous species, *Neotiella crozalsiana*, a Discomycete fungus with very similar characters except for a "persistently juvenile form of cleistocarpic operculate apothecium". *Nectria egens* is, of course, a definite Pyrenomycete, and the paper raises interesting questions as to fundamental differences between Discomycetes and Pyrenomycetes, other than the form of the fruit body.

Brown Rot Diseases of Fruit Trees. Bulletin No. 88 of the Ministry of Agriculture and Fisheries is devoted to "The Brown Rot Diseases of Fruit Trees" (London: H.M. Stationery Office, 1935. 1*s*. 6*d*. net). It is, perhaps, rather significant that this imposing monograph, which is the work of Dr. H. Wormald, replaces a short leaflet of three or four pages. The Ministry has performed a useful service to the fruit-growing community in thus collecting Dr. Wormald's research papers and utilising his special knowledge to review the extensive literature on the subject. This has been accomplished without prejudice to the needs of the practical grower, for descriptions of symptoms and advice on control can easily be separated from the more technical part of the volume. The history of the appearance of brown rot fungi is traced since the first mention of *Monilia fructigena* by Persoon in 1796. It is only of recent years, however, that other fungi have been recognised as causal agents of brown rots. *Sclerotinia* (= *Monilia*) *fructigena*, *S. laxa*, *S. laxa* forma *mali*, and *S. fructicola* are described in the work under review, and cultural characters are also given. A valuable feature of the bulletin is its international nature, which allows a survey of geographical distribution of the fungi to be made, and also outlines their probable effects on commerce. Conditions conducive to infection, and the mode of entry into the host plant are adequately treated, whilst symptoms and control of brown rots on apple, pear, cherry, peach, nectarine, apricot, quince and medlar are described. Twenty-four pages of excellent half-tone illustrations enrich the text, and six pages of bibliography should be very useful to the plant pathologist.

Chymase and Protease in Micro-organisms. A year or two ago, Prof. Constantino Gorini showed that the ability of bacteria to coagulate milk may be revealed by pouring milk which has been lightly sterilised on to the surface of a culture of the organism on agar containing such stimulants as broth, peptone, vitamins, yeast water, blood, etc. In a paper read before the Reale Istituto Lombardo di Scienze e Lettere in November last and published in the *Rendiconti*, 67, parts 16–18, Gorini describes the results of the application of this method of examination to a number of bacteria of various types. Among these were 115 strains of *Streptococcus*, of different origins and belonging to 16 different pathogenic species. When inoculated directly into milk, these showed negative or irregular results. On the basis of the chymase and protease indications of the milk-on-agar cultures, it was found that the organisms were divided between the three types, *Streptococcus pyogenes*, *S. agalactiae* and *S. lactis*. The procedure is hence of diagnostic value in distinguishing between chronic mastitis specific to lactifers and harmless to man, and the acute mastitis the infecting agent of which is transmissible to man through the milk. A number (18) of strains of *B. typhi flavum* of various origins and eight physiological variants of *B. typhi*, Eberth, all displayed, however, similar behaviour, no differentiating criteria being observable. Extension of the method is suggested as a possible means of distinguishing between bacterial species.

Apparent Magnitude in Scenery. Scenery, being a pictorial impression of the outdoor world, does not lend itself to direct measurement, which impairs the spontaneous effect on which the impression depends. In a paper on "Apparent Magnitude in Natural Scenery" in the *Geographical Journal* of March, Dr Vaughan Cornish attempts to discover some principles applicable to the study, using as his material outline drawings of landscape which he has been in the habit of making, without any direct measurement, during the past forty years. Thus, for example, he compares two alpine panoramas each including the rising sun, drawn at distances of four and forty miles respectively. In the latter case the sun's area was increased 3·16 times the former. The customary explanation is the mental comparison of magnitude between the unvarying sun and the varying angle of the landscape, and in other words that the mountains diminished in size as their distances increased and that the increase in the apparent size of the sun was inversely proportional to the change in the apparent magnitude of the mountains. But an examination of the drawings, of which the view-point was known, showed that the diminution in the apparent magnitude of the mountains was much less than the increase of their distance, and simple measurements revealed the fact that the distant mountains were subjectively magnified to the same extent as the sun. Another among many suggestions in the paper is that the more the eye takes in vertically the more it takes in horizontally and the less impressive are both dimensions.

Radioactivity of Potassium and Rubidium. Klemperer (*Proc Roy Soc*, A, March 15) has investigated some anomalous and interesting features of the β decay of potassium and rubidium. According to Fermi's theory and Sargent's empirical rules, the decay period of a β transformation is connected with the upper energy limit of the β-spectrum, and if these rules are applied to potassium, they give a period of a few minutes or a few days, according to whether the β-transition is of the 'allowed' or 'forbidden' type. The measured half decay period is of the order $7 \cdot 5 \times 10^{11}$ years on the assumption that the heavy isotope, ${}_{19}K^{41}$, is alone active, and it is therefore necessary to examine alternatives to the simple reaction,

$$ {}_{19}K^{41} \rightarrow {}_{20}Ca^{41} + \beta $$

It must be noted that ${}_{20}Ca^{41}$ has never been found by mass-spectrum analysis of old potassium minerals. Gamow has suggested as alternative schemes, (1) the simultaneous emission of two β-rays, (2) an α-decay, followed by the observed β-decay which comes from a short-lived halogen atom, and (3) a slow β-decay followed by the observed β-rays which come from short-lived calcium and strontium atoms. Klemperer has examined the first coincidence Geiger counters, and the second and third by chemical separations and the use of a linear amplifier. The results were negative in each case. He suggests that the β-rays come from undetected, rare, but still long-lived isotopes, ${}_{19}K^{40}$ and ${}_{37}Rb^{86}$. The anomalous lifetime of these elements (with respect to the Sargent rules) would be explained if they had a large nuclear spin, the β-ray being then a kind of 'super-forbidden' transition. Newman and Walker (*Phil Mag*, April) also suggest that the radioactivity of potassium may arise from ${}_{19}K^{40}$ or ${}_{19}K^{41}$ and that of rubidium from ${}_{37}Rb^{84}$, ${}_{37}Rb^{87}$ or ${}_{37}Rb^{88}$. Their suggestion that these isotopes could be produced experimentally by neutron bombardment is probably not practicable.

Discovery of Mephitic Air. In 1772, Daniel Rutherford (1749–1819), professor of botany in the University of Edinburgh, published his "Dissertatio Inauguralis de Aere Fixo Dicto aut Mephitico", in which he announced among other matters his discovery of 'noxious air', afterwards called nitrogen. In *Science Progress* (29, 650, 1935), D McKie has made an interesting analysis of the part of the dissertation concerned with nitrogen and shows that, contrary to the usual statement, Rutherford did not use the name 'mephitic air' for this gas, but for the 'fixed air' (carbon dioxide) discovered by Black, referring to nitrogen as another species of noxious air. He found that when an animal was confined in a limited volume of air it presently expired and the air was reduced in volume and rendered incapable of supporting fire or life. Removal of 'fixed air' by alkali did not restore it to its former wholesomeness. The relations to Priestley's discoveries are considered, and it is concluded that Rutherford's work was quite independent. Rutherford did not arrive at any clear explanation of his results, and did not see that the 'noxious air' (nitrogen) was a constituent of the atmosphere, regarding it rather as air combined with phlogiston.

A New Relativity Theory. A second instalment of Sir Shah Sulaiman's new theory of relativity has appeared (*Proc Acad Sci U P India*, 4, 217), the first part appeared in the same journal (4, 1) in August 1934. The author retains Euclidean space, and as much as possible of Newtonian dynamics, the chief deviation being the hypothesis that gravitational, electrical, and magnetic forces do not act instantaneously, but are propagated with a velocity nearly equal to that of light. Light is supposed to consist of 'radions' emitted from the surface of bodies, and gravitation of 'gravitons' from their entire mass. From these hypotheses four 'universal principles' are deduced. Two of these, akin to Doppler's principle and aberration, deal with the modification of the magnitude and direction of the gravitational force upon a moving body, and these are applied to the advance of the perihelion of Mercury, the deflection of light by gravitation, the spectral shift, and the experiments of Michelson and Morley, and of Bucherer. Another gives a formula for the relative velocity of two moving bodies, which is applied to the experiments of Fresnel and of Fizeau. The remaining one is applied (in outline only) to the fine structure of the hydrogen spectrum. The idea of an expanding universe is firmly rejected, though it is allowed that some nebulæ, formerly part of our galactic system, have left it on parabolic paths. In short, an attempt is made to give an alternative explanation for the whole range of phenomena usually adduced in support of Einstein's theory. It is difficult to form a definite opinion whether the author's work is entirely sound, but he has evidently studied all the standard works. The mathematics has been checked by two competent mathematical physicists, and the work has been carried out with the encouragement of Prof M N Saha. If it can stand the test of criticism, it will obviously be of great importance.

Social and Economic Conditions of West Australian Aborigines

THE report of a Commission of Inquiry on social and economic conditions among the aborigines of West Australia and the working of the State system of protection, which was published on March 12 last, criticises strongly the inadequacy of the provision for medical attention, the inefficiency of the care for half castes and the wasteful and unsatisfactory character of the management of the Moore River settlement. The Commissioner, Mr H D Moseley, is doubtful of the success of the missions among the aborigines, and he finds that allegations of cruelty and ill treatment of the aborigines, which have appeared in the public Press from 1930 onward, are without foundation

In the north and north west, natives on pastoral properties, the Commissioner reports, experience conditions which as nearly as possible approach their natural life. The work of the aborigines employed on stations takes an appropriate form, and the only criticism of the Government stations is that a greater effort should be made to keep the aborigines more constantly employed. The 'bush' natives are best left alone, and the land now occupied by them should be secured inalienably as a reserve and additional land should be set aside for reserve purposes in anticipation of closer white settlement in the northern area. The native is under no hardship through the non payment of wages, and there is nothing approaching a condition of slavery. In the north-west, where the wage system has been in operation for some time, it has encouraged the gambling and squandering habits of the aboriginal

To meet the inadequacy of the present medical attention available, the establishment of clinics and hospitals is recommended at four points to facilitate early diagnosis and treatment. Farther south, in the areas of closer settlement, increased hospital accommodation is recommended, the existing accommodation being both inadequate and undesirable in character. In addition to providing first-aid stores, employers of labour should be required to make payment into a medical fund on account of each employee, and in this connexion the present system of licenses for labour is criticised, as it does not require particulars of individual employees to be reported, but merely the total number employed. A system of registration is therefore recommended

In dealing with leprosy, the inadequacy of the provision for segregation of detected cases awaiting transhipment to the leper hospital at Darwin, and the delay in evacuation are strongly criticised. It is suggested that the State should withdraw from the arrangement whereby leprosy is made a Federal concern and provide a leprosarium of its own on one of the islands off the coast, but if this is impossible, that suitable arrangements should be made for isolating detected cases, while the inspection for leprosy and venereal disease, for which agitation has been going on since 1924, should be held forthwith.

If conditions in the sparsely settled north and north-west can be regarded as satisfactory on the whole, except as regards the medical question, it is far otherwise in the more closely settled south, where the aboriginal has come more closely into contact with white civilisation, and native camps are situated in close proximity to the towns. In the Moore River settlement, children and young persons are being educated and trained in close proximity to the camps for indigent aborigines, without proper measures being taken to keep them apart, hence most undesirable results, especially as affecting young girls. The buildings are inadequate, verminous and inefficient, and proper educational equipment is lacking. The care of half castes is thoroughly inefficient and inoperative. So far as possible, camps should not be allowed to remain near the towns. It is recommended for both able-bodied aborigines and half-castes that a system of farm-stations should be established on which adults and parents could work on their own allotments, while the children were trained for suitable occupations. An extension of the existing arrangements for the training of girls for service and other occupations is also recommended.

In regard to the laws affecting aborigines, the most important measure suggested is the provision of special courts for the trial of 'bush' natives, in which the proceedings would be suited to the code of the native and such as he himself and the members of his tribe would understand. The holding of such courts might be part of the duties of a district protector on patrol

It is pointed out how far the criticism of existing conditions is concerned with matters which can be attributed to the defects of the present organisation of protection, whereby the Chief Protector, assisted by more than a hundred honorary protectors, who do not function except to grant permits to employ labour, has been overburdened with office work and has been unable to travel and inspect actual conditions. A reorganisation is recommended in which the office of Chief Protector should be abolished, and his place taken by a secretary of the Department, who would be responsible for office detail, while the active work of protection would be in the hands of district protectors, of whom one, a medical man, should be appointed to the northern area forthwith.

The Collection of Dew

By H. E. BECKETT and A. F. DUFTON

ARISING from the serious shortage of water in many districts during the summers of 1933 and 1934, the suggestion was made that the collection of dew would be profitable and that research should be undertaken into the economic design of dew-ponds. A little consideration showed that certain types of roofs, suitably insulated underneath, might act as economical and efficient collectors of dew.

If 'dew ponds' really do collect dew owing to the cooling either of the water surface or of the surrounding banks below the dew point, by radiation to the night sky, even more dew should be collected on a thin metal roof of low thermal capacity, provided that the roof has an efficient radiating surface and is prevented from gaining heat from below.

In order to find whether sufficiently low temperatures could be obtained on thin metal sheets and to what extent these temperatures were affected by

surface treatments of the sheets and by the amount of insulation beneath them, four galvanised iron sheets, measuring 4 ft. 3 in. square, were supported off the ground and exposed out of doors at the Building Research Station. One sheet was left plain, another was formed into a shallow tank and filled to a depth of 1 in. with water, the two remaining sheets were whitewashed on the upper surface and one was provided with 7 in of cork insulation underneath

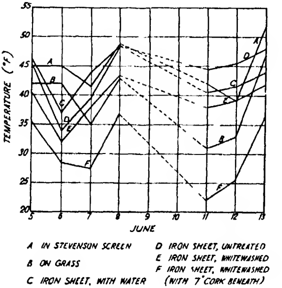

FIG 1 Minimum temperatures

Each sheet was provided with a thermocouple by means of which its temperature was recorded The minimum temperatures recorded on a number of nights in June are shown in Fig 1 It will be seen that the specimen which was whitewashed on top, to reflect the sun's heat by day and to radiate heat by night, and was heavily insulated beneath with cork, became appreciably colder than any of the other specimens, the lowest temperature recorded being 22° F, 20° F below the screen minimum for the night

The next step was to experiment on a larger scale with an actual roof, to find how much dew could be collected For this purpose a section of a corrugated iron roof, 18 ft 7 in long by 11 ft wide and having a pitch of 7½°, was provided with separate drainage. The roof was insulated underneath with two sheets of aluminium faced asbestos paper, spaced 1 in apart, the equivalent of about 1 in of cork, and was whitewashed on top The temperature of the iron sheets was recorded by means of a thermocouple

Measurements were made on this roof on suitable clear nights from July to September, but the results were disappointing Dew *could* be collected on nights most favourable for the loss of heat by radiation, but suitable nights were by no means frequent, and, even then, the amount of dew collected was small A typical record is given below

Dew Collection on Night of Sept 21-22

Minimum roof temperature	28° F
Minimum screen temperature	36½° F
Grass minimum	29° F
Minimum temperature on bituminous felt on adjacent flat roof with 7 in of slag-wool insulation underneath	25½° F
Dew collected	70 cu in

The quart of water which is obtained on a night when the sky is propitious is a mere dribble compared with the 10 gallons which the same roof collects during 1/10 inch of rainfall, and it is obvious that, as an auxiliary water supply during drought, the collection of dew in this way cannot be seriously considered Storage for rain water is more economical to instal, more reliable and altogether more practicable

From the experiments described above, it may also be inferred that the action of 'dew ponds' cannot be ascribed to the ordinary deposition of dew This corroborates the findings of E A Martin[1], who as a result of an extensive study, decided that the ponds depend for their replenishment upon mists rather than dew and that the term 'dew pond' is a misnomer According to Martin, the word 'dew pond' does not appear to have been used prior to 1813 ("The Shorter Oxford English Dictionary" gives the date 1877) and, since then, although some ponds have borne that name others have been known as 'cloud ponds', 'mist ponds' or 'fog-ponds'

Sylvicultural Research in Nigeria

SINCE the appointment of two sylviculturists for research in Nigeria in 1928, a remarkable amount of good work has been undertaken in connexion with the rain and moist deciduous forests in the south-western provinces In the *Oxford Forestry Memoirs*, No. 18 (Oxford, The Clarendon Press, 1934), Mr W D. MacGregor, one of the sylviculturists, publishes an account of his work in a brochure entitled "Sylviculture of the Mixed Deciduous Forests of Nigeria, with Special Reference to the South-Western Provinces".

The mixed deciduous forest type in West Africa is an important concomitant of the forest flora, coming between the true deciduous and the true evergreen forest types. Botanically it includes high forest trees of both types, but differs from the deciduous forest in containing evergreen under canopies, and from the evergreen or rain forest in containing top canopies of deciduous trees

From the forester's point of view, the mixed deciduous forest type is nearer to the deciduous than to the rain forest type It is in reality a climatic formation in which deciduous trees attain their optimum development In its most humid form, the mixed deciduous merges imperceptibly into the rain forest type It requires a rainfall averaging 50-70 inches per annum

Of the numerous natural orders of this forest type, *Sterculiaceae*, *Leguminosae*, *Moraceae* and *Combretaceae* are the most important The two magnificent trees *Triplochiton scleroxylon* and *Chlorophora excelsa* have the greatest range in distribution

With the evergreen forests to the south and the deciduous forests to the north, the mixed deciduous

forests form an almost continuous belt of varying width running parallel to the coast They are said to hold great timber wealth of large dimensions They have not been exploited, however, to anything like the extent of the rain forests owing to their geographical position, which places them outside the zone of streams and rivers suitable for floating timber

The object of Mr MacGregor's memoir is to record all the experimental and research work in connexion with the sylviculture of the mixed deciduous forest type upon which he has been specially engaged, or on which other officers have obtained some experience of, for example, plantation work In the latter work, fuel plantations have formed an important branch Large areas of indigenous species have been planted at Akilla, Ondo Circle At Mamu and Olokemeji teak has been successfully grown—but almost, until recently, at the expense of good local indigenous species Latterly, however, research work in the nursery and plantation has been devoted to the study of the requirements of indigenous species with the view of replacing exotic species when possible

It is a curious anomaly that here in the West African tropical forests, with a plethora of magnificent timber trees of which almost the only one known, during the past century at least, was mahogany, the first commencements of forest plantation work on a scientific basis should have been made with teak in several colonies to the neglect of some of the, admittedly little-known, indigenous species The research work with the latter undertaken by Mr MacGregor and ably depicted in this memoir proves that West Africa has timbers which will probably, in the future, be able to hold their own on any timber market in the world

In addition to the nursery and experimental plantation work undertaken with indigenous species, sylvicultural experimental work in connexion with both artificial and natural regeneration has been commenced with considerable success

Chapters are devoted to the description of the sylvicultural characters of a number of species, indigenous and exotic, and some excellent descriptions of seedlings Finally, there is a report on the soils at Olokemeji by Mr H C. Doyne, senior agricultural chemist, and Mr W. A Watson, agricultural chemist, Ibadan

Although perhaps it is too early to accept the mass of detail recorded in this important memoir as actually proved, without further check, yet Nigeria may be complimented on the methods upon which the work has been carried out

The Broadcasting Wave-Lengths of Europe

THE plan for allocating the wave lengths of the broadcasting stations in Europe published in 1934, and known as the Lucerne plan, is getting more and more difficult to work The trouble arises mainly from the fact that the full range of frequencies available for the carrier waves is 1,350 kilocycles per second, and in order to prevent serious overlapping, each station requires a width of about 10 kilocycles per sec. In order to secure agreement between the various nations concerned, it was necessary to allocate 133 channels to 170 working stations, so that some had to work at the same frequency, care being taken to give these frequencies to small stations at a great distance from one another.

Unfortunately, little attention had been given to limiting the power of large broadcasting stations, and so there are now thirteen in Europe which work at 100 kilowatts or above, eighteen with powers not less than 50 kw and twenty with powers not less than 20 kw Many of these stations are transmitting through the same zone of darkness, and it follows that the spectra of the waves radiated by powerful stations in contiguous channels will overlap The overlapping sidebands of these unwanted stations produce serious interference

In a paper on broadcast transmission read to the Institution of Electrical Engineers on May 1 by Mr P P Eckersley, it is pointed out that at the present time the designer of a receiver capable of reproducing distant as well as local programmes is forced to cut off the upper audio frequencies of modulation, and this deleteriously affects the quality of the reproduction The ordinary commercial receiver sold to-day to the public cuts off the audio frequencies above 3,500 cycles per second

The only way to get over this difficulty is to change radio technique. It is improbable that European nations will agree to limit either the existing power or the number of their working stations But if it were possible to modify transmitters so that the spectra of the waves radiated contained the carrier wave and only one set of sidebands, spectrum overlap could be minimised and in some cases entirely eliminated. If a frequency band of 2,000 cycles per second could be added to the ordinary breadth, a great improvement would result. The introduction of high-fidelity broadcasting would undoubtedly stimulate the industry of radio broadcasting

Mr Eckersley has recently been to the United States and has inspected the apparatus developed by Wired Radio Inc for use in connexion with their high-frequency broadcasting system He found that several of the methods he recommended were similar to their methods, and that a very high quality of reproduction was achieved

University and Educational Intelligence

CAMBRIDGE —The sixth course of Scott Lectures will be given by Prof G Hevesy in the Cavendish Laboratory at 4 30 p.m on May 13, 15 and 17 The subject of the course will be "The Terrestrial and Cosmic Abundance of the Elements".

An election to the Isaac Newton Studentship will be held in the Michaelmas Term 1935 These studentships are for the furtherance of advanced study and research in astronomy and physical optics and are open to those members of the University who have obtained a degree in the University and were less than twenty-five years of age on January 1, 1935 Candidates are invited to send in their applications to the Vice-Chancellor between October 8 and 14, 1935 The emolument of the student will be £250 per annum

EDINBURGH —Mrs. Stewart Hall has given £15,000 for the endowment of a lectureship in the pathology of the diseases of children

On the recommendation of the Joint Committee of the University Court and the managers of the Royal Infirmary, Dr. A E Barclay, lecturer in medical radiology, University of Cambridge, has been appointed lecturer in radiology in the University, on his appointment as radiologist to the Royal Infirmary from May 1, 1935.

THE International Federation of University Women held a meeting at Budapest in September last, when twenty-six national federations were represented. Among the resolutions adopted was one deprecating the "tendency, increasingly evident in the majority of countries, by new regulations to debar women from careers for which they are well qualified, whether on grounds of sex or marriage" and declaring such regulations to be "inimical to the family which is itself the foundation of society". Another deplores the contravention in certain countries of the principles that teaching history, etc., in schools should be impartial and that art, literature and science are a common human heritage and not the appanage of particular nations or races. The German Federation has passed through a difficult period, and it is hoped to reconstruct it on a basis which will eliminate discrimination on any racial, political or religious grounds. The Austrian Federation was concerned about the bad effect of recent legislation on the position of women. The Indian Federation reported a surprisingly large number of members -400. The British Federation gave scholarships last year enabling three German scholars and scientific workers who had lost their positions on account of their non-Aryan nationality or political opinions to live at Crosby Hall, London. The next conference of the International Federation is to be held in 1936 in Poland.

"FREEDOM or Indoctrination: an Enduring Dilemma of Education": a paper by Prof. Marvin L. Darsie of the University of California, contributed to *School and Society* of February 2, deals judiciously with this theme—one that is in the forefront of current educational topics of discussion in the United States. The recent development in Germany of authoritarianism in educational as in other fields has proved a powerful irritant provoking such discussion. Prof. Darsie's paper attempts an analysis of some of the complex factors associated with capitalism, scientific technology and the increasing solidarity of organised labour, in which the age-long conflict between the advocates of free intellectual inquiry and the guardians of established doctrine is to-day entangled. Starting from the position that the concepts of freedom and indoctrination have to do with the interweaving of the "two innately conditioned desires for self-expression or pre-eminence and security within the immensely complex maze of social patterns constituting a culture or civilization" he proceeds to consider the resulting problems confronting the educator. The public school teacher functions in an agency maintained by society for the direct purpose of indoctrinating the young with the established institutional patterns; but these represent nuclei of public opinion substantial at the core but with continuously fluctuating margins. It is peculiarly the function of the enlightened teacher "to keep alive this fringe of experimental thinking and at the same time to prevent its detachment from the institutional matrices which guard the stability of any organized society". In this delicate task he must beware of endorsing or promoting any propagandist movement, but his obligation to human welfare requires him to defend and preserve the fringe of free experimental inquiry. The dilemma is discussed in terms of national policies in a short article, "The Great Rift in Education", by Dr. J. F. Abel in *School Life* of December.

Science News a Century Ago

Loads Carried by South American Miners

On April 27, 1835, Darwin set out from Valparaiso on horseback for Coquimbo, which he reached on May 14. On May 12 he stayed at some mines, and writing of the loads carried by the miners, he said: "Captain Head has described the wonderful load which the 'Apires', truly beasts of burden, carry up from the deepest mines. I confess I thought the account exaggerated; so that I was glad to take an opportunity of weighing one of the loads, which I picked out by hazard. It required considerable exertion on my part, when standing directly over it, to lift it from the ground. The load was considered under weight when found to be 197 pounds. The apire had carried this up eighty perpendicular yards, —part of the way by a steep passage, but the greater part up notched poles, placed in a zigzag line up the shaft. According to the general regulation, the apire is not allowed to halt for breath except the mine is six hundred feet deep. ... These men, excepting from accidents, are healthy and appear cheerful. Their bodies are not very muscular. They rarely eat meat once a week, and never oftener, and then only the hard dry charqui. Although with a knowledge that the labour was voluntary, it was nevertheless quite revolting to see the state in which they reached the mouth of the mine; their bodies bent forward, leaning with their arms on the steps, their legs bowed, their muscles quivering, the perspiration streaming from their faces over their breasts, their nostrils distended, the corners of their mouth forcibly drawn back, and the expulsion of their breath most laborious. ... After staggering to the pile of ore, they emptied the 'carpacho', in two or three seconds recovering their breath, they wiped the sweat from their brows and apparently quite fresh descended the mine again at a quick pace ...."

Bird Distribution

Much new light on the distribution of bird life outside Europe was shed at the meeting of the Zoological Society of London on May 12, 1835, with Mr. N. A. Vigors in the chair. The skin of a kiwi, *Apteryx Australis*, Shaw, sent by the Colonial Secretary for New South Wales, was exhibited, along with an account of the habits of the bird, its probing of the ground with its long bill for earthworms and its scant distribution in New Zealand, whence it had been obtained by a correspondent who had seen only two during his stay there. Colonel Sykes exhibited a series of bird skins presented to the Society from the Cape region of South Africa by Capt. Spiller, and these, stated Sykes, had enabled him to make a comparison with the collection of birds he had shot in India, and those of Europe, to draw up a list of fifteen species of bird found equally in South Africa and India, four species found in South Africa, India and Europe, and two species 'universal', providing *Strix Javanica*, Horsf. was identical with *Strix flammea*, Linn. A female hybrid pheasant, *Phasianus colchicus*, produced by a cock pheasant and greyhen (*Tetrao tetrix*) from the Merrington Covers of Mr. R. A. Slaney, near Shrewsbury, was exhibited and described by Thomas C. Eyton.

Geology of Seeland and Möen

At a meeting of the Geological Society on May 13, 1835, Lyell read a paper entitled "On the Cretaceous

and Tertiary Strata of the Danish Islands of Seeland and Möen" According to a report in the *Philosophical Magazine*, "Mr Lyell examined, in company with Dr Forchhammer, the cliffs of Seeland and Möen during the summer of 1834, and the following are the results at which he arrived The two formations of which Denmark and Danish Holstein chiefly consist are chalk, and an overlying tertiary deposit Part of the latter resembles in composition the argillaceous and sandy beds of the English crag Another part corresponds with deposits usually called diluvial, especially those associated with the English crag, in parts of Norfolk Large erratic blocks are also strewn over the surface of Denmark, connected with, and sometimes buried in the gravel, or 'diluvium' In some sections on the banks of the Elbe, the yellow tertiary sands are divided regularly into thin strata and are exposed for a thickness of about 200 feet The white chalk of Denmark is characterised by the same fossils as those of the upper chalk of France and England"

Water from the Well of Zem-zem

At a meeting of the Royal Society on May 14, 1835, a communication from John Davidson was read giving "An Account of the Water of the Well Zem-zem, with a quantitative analysis of the same by Professor Faraday" Davidson had sent home about three quarts of the water from the well of Zem-zem near Jedda, to which the Mohomedans ascribed a sacred character and extraordinary virtues The can containing the water had been sealed, but unfortunately it had been opened in the London Docks and the gas with which it was charged had escaped The precipitate thrown down was found by Faraday "to consist of carbonate of protoxide of iron in the enormous proportion of 100 8 grains to the imperial pint of water The clear liquid was neutral and contained much muriate, and a little sulphate but no carbonate, together with a little lime, potash and soda There was also found an alkaline nitrate in considerable quantities, this Mr Faraday conjectures to have been saltpetre, which had been added to the water by the priests"

Large-Scale Research in Crop Production—Cotton*

ORGANISED research in furtherance of industry has, in proportion to the interests involved, developed more slowly for agriculture than for industrial commodities or for processing or for transportation The work of the Empire Cotton Growing Corporation, one of the youngest and now one of the strongest organisations for research on crop production, is, however, an example of bold development The raw cotton position just after the War, when Great Britain was dependent on the United States for a very high proportion of her supplies, led to the founding of the Corporation in 1921 Production in the newer Empire fields (that is, excluding India) has since then increased from 30,000 to 90,000 tons The financial support of the Corporation has come largely from the cotton spinning industry which, by promotion of research throughout its own grave depression, has shown striking faith in science In brief, it is the object of the Corporation "to put the Empire into such a position that it can and will produce, within economic limits, its proper share of the cotton required by the world "

This main objective is easily seen to resolve into a great array of problems Where cotton is a more or less familiar crop, increase of yield and improvement of quality bring up difficult questions of disease, of soil fertility, and in some cases of irrigation But a great increase in the Empire's cotton area is clearly indispensable, and is only possible by extension to territories where cotton has not been grown at all or only scrappily, for simple local use Here are added to the problems of established cotton areas many new, intriguing issues Suitable varieties must be found or made. Labour must not only be trained but also, if possible, made more effective by displacing hand tools—for the available new areas are largely in East and West Africa—by cattle-drawn ploughs and hoes In devising appropriate systems of cropping and cultivation for the new areas lie some of the most important problems Ancient systems, resting on some form of 'shifting' cultivation, do not readily admit a wholly new crop, and that a cash crop, on any extensive scale Further, the terrible menace of soil erosion hangs over orthodox weed-free methods in many places, while maintenance of

* Empire Cotton Growing Corporation A Review of the Work of the Experiment Stations, Season 1933–34 By Dr J C Willis Pp. 38. (London Empire Cotton Growing Corporation, 1935) 1s 6d

fertility is a problem of which green manuring, an old, unsolved question of the most progressive European countries, is but a part There are, too, considerable issues in ensuring supplies of seed, in grading, marketing and transport.

The Corporation has provided for the study of its problems by setting up stations, twelve in number, which besides working independently, collaborate with the agricultural departments of their territories A post-graduate scholarship scheme has been used to provide a large part of the scientific personnel

This great research organisation is governed by the Director of the Corporation, with advice from a small scientific committee, which meets in London Stations have substantial freedom in determining, appropriately to their circumstances, the balance between primarily scientific and more empirical and immediate investigation A purely scientific research station in Trinidad (not included in the "Review") is maintained for studies in which central effort and the most specialised resources are required

Suitable collaboration and mutual assistance among twelve widely dispersed and variably circumstanced stations demand—perhaps it is the chief need—a most careful provision for interchange of views and experimental results A volume of progress reports is issued every year by the Corporation, but this leaves unsatisfied the needs of a great number who, as contributors to the research fund, or as investigators, or as administrators in the territories concerned, are deeply interested in the realisation of the Corporation's aims It is for them Dr Willis's review, with its admirable brevity and simplicity, is issued

It is natural to find plant breeding the most prominent part of the stations' work, for in new circumstances improved varieties frequently offer the earliest opportunity for agricultural progress A selection made by F R. Parnell, of the Corporation's staff in South Africa, has, under the name of 'U 4', now become famous Its great value arises from its strong, inherent resistance to the jassid (*Empoasca facialis*), an insect which formerly threatened to inhibit cotton cultivation over most of the southern half of the African continent

Dr Willis, in dealing with improvements in agricultural practice, refers to the importance of "work which has a definite bearing, not upon cotton as cotton, but on its satisfactory, efficient, and economical insertion into the general agriculture of the country" This obviously right, though far from common, attitude in research on a single crop, gives to the agricultural studies of the various stations an admirable range and soundness The actual problems are as diverse as the countries in which they occur—Australia, Rhodesia, South Africa, Fiji, Sudan, the West Indies, and many parts of East and West Africa. The Corporation may be assured that an annual review in the form and the style Dr Willis adopts in this first essay will be widely appreciated

Reviews

Evolutionary Morphology of Plants

Primitive Land Plants, also known as the Archegoniatæ By Prof F. O Bower. Pp xiv+658 (London Macmillan and Co, Ltd, 1935) 30s net

THE publication of a new work by Prof F O Bower dealing with the Archegoniatæ is an event of importance in the study of the morphology of plants. For Prof Bower, who has contributed largely to our detailed knowledge by his investigations, has never rested content with mere description. He has always aimed at bringing the facts under general conceptions or hypotheses His work has thus never lost the impulse of the evolutionary point of view, whether it has been a direct quest for phyletic lines or, as he here puts it, an attempt "to visualise the Methods of Advance which these primitive Land-Plants appear to have followed in their evolution" That he has retained this aim and the faith that it may be reached is closely connected with his work having been concerned with the Vascular Cryptogams or Pteridophyta, for these present exceptionally favourable material for evolutionary morphology They can be studied apart from the later evolved Gymnosperms and Angiosperms, they are represented by varied living forms and they have a wonderfully good and instructive fossil record.

The Vascular Cryptogams are here considered in relation to the Bryophyta, as was the case in "The Origin of a Land Flora", published twenty-seven years ago The subject matter is the same, but "Primitive Land Plants" is an entirely new work. The changes in interpretation are due to Prof. Bower's responses to the additions in the interval to our knowledge of the facts The book is divided into two parts: Part 1, which occupies

two thirds of its length, deals descriptively with the main subdivisions or classes of Bryophyta and Pteridophyta The treatment is objective and general interpretations of the morphology are only foreshadowed These general views emerge into full treatment in Part 2, in the course of a discussion for which the descriptive portion provides the data

The descriptive account of archegoniate plants is written with the clearness characteristic of Prof Bower, and is illustrated by a well-selected set of figures, many of which have hitherto had to be sought in original papers This up-to-date survey will doubtless prove a much needed textbook for students, though this is not its main purpose The "Origin of a Land Flora" was used with great gain in this way, and the present book has the advantage of dealing with both generations in the life-history

Tempting as it is to dwell on the treatment of the various groups as described in Part 1, it seems more desirable to bring out some of the author's general conceptions and conclusions Attention is directed throughout the book to the new light which is thrown on many features of both generations by considering relations of size and form There is further an excellent brief general treatment of the theory of size as applied to the vascular system in Chapter xxviii As regards alternation of generations in land plants, the position taken up remains essentially that of the "Origin of a Land Flora", though modified in details The interesting types of alternation in brown and red algæ are not regarded as bearing directly on the origin of the Archegoniate sporophyte This is still held to be a stage interpolated in the course of evolution between syngamy and meiosis Nor is there any change in principle in the treatment of the prothallus and gametangia or of the embryology The latter leads to the recognition of the primitive spindle, which finds its prototype in the Bryophyte sporogonium, can be connected with Zimmermann's theory of the telome and leads to the increasingly elaborate plant-body of the Pteridophytes. This is seen in its simplest form in the dichotomously branched leafless Rhyniaceæ, and the novelty of the author's evolutionary conceptions becomes evident in considering various progressions from this.

The title of Chapter xxvii, "Axes and Leaves", is intended to indicate that 'leaves' may not be, and indeed almost certainly are not, referable to one type This is generally accepted when the leaves of the gametophyte as well as the sporophyte are under consideration. The more difficult question concerns the simple and often small leaves of the Psilotales, Lycopodiales and Equisetales on one hand, and the large and compound leaves of the Filicales on the other In the "Origin of a Land Flora", the megaphyllous type was derived from the microphyllous, by increase of size and elaboration of the leaf relatively to the stem bearing it A fundamental distinction in origin is now drawn between cladode leaves or megaphylls and microphylls or *Thursophyton* leaves The strong evidence for the interpretation of the fern frond as derived from an increasingly specialised branch-system is clearly stated It explains many details, and leads back to the conception of axis and cladode leaf being referable in origin to a common scheme of distal forking

In emphasising the distinctness of the microphylls from the cladode leaves the alternative term, *Thursophyton* leaves, indicates the weight now attached to the early fossils Diagrams of the spines or leaves of *Psilophyton*, *Asteroxylon* and *Arthrostigma* bring out the facts of construction clearly The origin of such leaves in the transition region of *Asteroxylon* and of the Psilotaceæ is most naturally interpreted as by enation and not by branching On our present knowledge, there is a strong case to be made out for progressions starting from the wholly leafless branch-systems illustrated by the Rhyniaceæ towards the two types of foliar development A further question is raised by the inquiry whether in ferns with their cladode leaves there are parts comparable with the spines or leaves of microphyllous Pteridophyta The dermal appendages of ferns have features in common with the microphylls, and comparisons, which may have morphological importance, can be instituted between them It is pointed out, however, that the resemblances may be homoplastic and not homogenetic

What is brought out by the comparative survey of the vegetative organs of Pteridophyta acquires further significance in the light of the examination of the spore-bearing members in Chapter xxix Again only salient points can be noted The Bryophyte sporogonium, especially as illustrated by that of *Anthoceros*, comes into the comparison not only by way of the problematical *Sporogonites* but also because of the general features of the undoubtedly vascular *Hornea* and *Rhynia* This leads to a conception of the elaboration of form by way of the branching of a sporogonium-like structure The sporangia, terminal in *Rhynia*, may be grouped in leafless strobili as in *Zosterophyllum* Condensation of the ultimate fertile regions of a branch-system gives a natural key to the sporangiophoric condition To this leafless type of plant the enation of microphylls in the region intervening between the rhizome and the fertile *Hostimella*-like region introduces a further complexity, as illustrated by *Asteroxylon* In some advanced Vascular Cryptogams, notably in

Equisetum and *Archæocalamites*, the fertile region consists of sporangiophores borne on a main axis without any associated 'leaves' Comparison with other extinct Equisetales suggests the invasion of this fertile region by microphylls which become a very definite feature of the strobilus A similar explanation is shown to be applicable in the Psilotales and Sphenophyllales The constancy of the relation of sporangium and sporophyll in Lycopodiales presents an evident difficulty, but in this connexion it is possible to point to the condition in *Zosterophyllum*, where large sporangia of Lycopod-type form a strobilus free from leaves While there are no forms showing the invasion of such a fertile region by microphylls, the starting point is illustrated by a known plant

The above is a condensed statement of a new and interesting interpretation of the strobilus of microphyllous Pteridophytes Morphologists will have to refer to the evidence in full as it is given in various parts of the book It should be added that, just as a possible equivalence of the dermal appendages of ferns with microphylls was suggested, so a broad correspondence can be traced between the sorus of ferns and the sporangiophore The parallel can be further extended, and the sorus with its indusium compared to the sporangiophore with its associated microphyll

It is scarcely necessary to follow the combination of the general conceptions, some of which have been considered above, into the organographic analysis of the plant in Chapter xxx and the summary of the whole argument in the concluding chapter Enough has been said to make it clear that this essay, as the author illuminatingly terms it in the dedication to the memory of Dr D H Scott, raises fundamental questions in the morphology of the Archegoniatæ We are led to consider again aspects of these plants that, unless we are to remain content with mere description, demand some evolutionary explanation Prof Bower brings before us the challenge of the facts and the solutions he can suggest These carry great weight from his life-long study of the group, though he would probably be the first to disclaim for them any finality But the play of ideas on the facts as known at present keeps interest alive, and new, clearly expressed conceptions are valuable, whether they come to be accepted or lead to the formulation of alternative views In either case our knowledge is made more coherent, and there is probably no other way in which evolutionary morphology can advance

The value of the conclusions thus lies partly in themselves, but perhaps of even greater importance is their effect as a stimulus to the search for further facts, whether in the comparative morphology of existing plants, in the fossil history or in experimental morphology That our general views and working hypotheses are other and fuller than if this book had not been written more than justifies what is said in a sentence on its wrapper "The author believes that at the end of a long life of research some comprehensive expression of opinion, however tentative and imperfect, would aid students who will carry on the work" It will indeed be recognised by all students of plant morphology that "Primitive Land Plants" adds greatly to the debt which they already owe to Prof Bower for "The Origin of a Land Flora" and "The Ferns" W H LANG

Israel in the Making

The Heritage of Solomon an Historical Introduction to the Sociology of Ancient Palestine By John Garstang (Herbert Spencer's Descriptive Sociology, continued by his Trustees, Vol 3) (Published for Herbert Spencer's Trustees.) Pp xv+439+4 plates (London Williams and Norgate, Ltd, 1934) 20s net

THIS contribution to the "Descriptive Sociology" planned by Herbert Spencer, and continued by his Trustees, is the third volume of the new octavo series, and a welcome contrast to the earlier folios But it seems to have been constructed round the Sociological Index (p. 395) of passages in the earlier books of the Old Testament, and consequently tends to lapse into minute enumerations of archæological or administrative detail, reminiscent of *Numbers* and *Deuteronomy* rather than of *Exodus*. Much of the topographical and strategical material of the author's recent *Joshua, Judges* has, however, been incorporated, and a summary of modern critical hypotheses and interpretations of Hebrew traditional history Perversely, however, Prof Garstang "carefully abstained from using" other people's "books as works of reference" and consequently has made some mistakes from which better acquaintance with the literature might have saved him

Prof Garstang's own wide experience of life in Palestine and of the 'methods and practice' of excavation furnish him with some interesting parallels and illustrations, but a characteristic inability to come to the point makes the book disappointing to use The 'J' and 'E' documents "refer most nearly to contemporary events" (p. 12), but to what events? And what is the "accepted theory" on p 339? "Three vast areas" (p. 13) are "peopled by a more or less kindred stock", but *what* areas, and *which* stock? The Canaanites (p 23) "were possessed of a formidable arm of war", but we have to wait to learn (p. 108) that their "chief offensive arm" was the chariot, and that Israel had it not. Allusions (p. 186) to

"money", "cash" (p 67–8) and "silver currency" (p 86), to an "arterial road" (p 339), to "democracy" in Gideon (p 113) and Philistia (p 257), to "theophoric names" (p 156), to "a kind of maize" (p 324) need explanation in a book intended to be popular on the other hand, it is unnecessary to explain 'cuneiform' more than once Oaxos is not on the coast of Crete, and Zagros not in Crete at all (p 231) unless Zakro is meant If "no distinctively Philistine interments have been recognized" how does the "crater-vase suggest cremation" (pp 234, 240, 243), seeing that this form is common in burial-chambers in Phœnicia, Cyprus and the Ægean? Surely the "only known attempt to represent Israel's God" on a coin should have had an illustration or at least be identified by reference to one It does not help much to visualise Solomon's buildings, to be told, as in the Authorized Version, that the doors "like the posts, were 'square in prospect'", and is it seriously suggested that the private chapels built for Solomon's wives "opened thinking minds to a broader conception of a Godhead that should comprehend all gods"?

Of Solomon himself, Prof Garstang thinks poorly Born in the purple, he dissipated his "heritage", and provoked reaction against monarchy and monotheism alike What is nowhere explained, however, is the unique fame of his "Wisdom", nor is there any serious attempt here to reconstruct the art, apart from the mere structure, of his Temple. Here, at all events, an excavator might be allowed to guess.

J L MYRES

Universities of the British Empire

The Yearbook of the Universities of the Empire, 1935 (Published for the Universities Bureau of the British Empire) Pp xxxi+1057 (London G. Bell and Sons, Ltd, 1935) 15s net

THE publication of the 1935 issue of this annual marks the attainment of its twenty-first year Like the goddess Minerva, with whom it has a certain affinity, being a yearbook of the learned world, it never knew infancy, but it bears to-day unmistakably the stamp of maturity It still retains its original characteristic features. (1) a section for each university containing a directory of the officers and members of the staff (the teaching staff being arranged under subject headings), general information about the university's organisation, regulations, etc., and reports of events of outstanding interest which occurred during the past year, (2) an index of names covering all the universities. To these have been added five introductory chapters dealing with the universities of Great Britain and Ireland, of Canada, of Australia, of South Africa and of India, a large number of appendixes containing a vast amount of information, conveniently displayed, about admission to universities, open post-graduate scholarships, professional associations, centres of scientific and industrial research and various other matters and a general index

The introductory chapters, dealing with the universities' histories, regulations and practice, are readable essays, striking a happy mean between the slap-dash and the unduly elaborate, and are kept up to date by frequent re-editing Of the appendixes, one shows the countries of origin of university students in the British Isles in greater detail than the returns of the University Grants Committee It appears that last year more than five thousand students came from abroad from continental Europe, 1098, Asia 1,739, Africa 888, America 1,070, Australia 355 Of the European students by far the largest quota came from Germany—436 France sent 81, Norway 47, Switzerland 45 and Holland 42 Another gives a useful short bibliography of works relating to universities When the Yearbook was first compiled it was hoped to arrange all its information in so orderly a fashion that no index other than the index of names would be needed The ideal was adhered to in theory too long after it had become obviously unrealisable in practice In recent years a good general index has been perfected A perusal of the Yearbook, necessarily rather cursory, has brought to light nothing to which exception could reasonably be taken except, perhaps, in the Durham Colleges section, a disconcerting entry "For early history, see Yearbook for 1929"

The Yearbook has suffered through the untimeliness of its birth—six months before the outbreak of the War—and though its valiant struggle for existence in the stormy period 1914–18 was successful, it found itself thereafter in a world in which the dominance of nationalism has unfortunately not been confined to the political and economic spheres A generation ago the Yearbook would have had a much larger circulation in foreign countries than it has to-day. Even within the Empire its circulation is not nearly so large as its potential utility should make it The preface characterises its contents as "such information as may be of interest to members of universities and colleges, to Government departments, clubs, schoolmasters and the public generally" But until public librarians and, it may be added, writers on university topics in the public press, recognise its merits more generally than at present, its utility to the general public will remain almost wholly latent.

Short Notices

General Astronomy By Dr H Spencer Jones Second edition Pp viii + 437 + 28 plates (London Edward Arnold and Co, 1934) 12s 6d net

SINCE the year 1922, when the first edition of the Astronomer Royal's "General Astronomy" was published, the progress of the science has been truly remarkable Naturally this cannot be said of all that broad field where advance has been slowly and laboriously consolidated by centuries of patient observation There is a very wide region where methods and ideas are static They retain their importance, but descriptions of them once given do not call for constant revision There is, on the other hand, a part of the science, chiefly in stellar astronomy, where the application of modern physical theory has changed the scene, and ideas are in a state of flux

The second edition of the Astronomer Royal's work preserves an account of those parts of the subject which may be regarded as standard, but it also includes a new treatment of that domain where progress has been most rapid The author has succeeded in conveying a remarkably comprehensive view of the present state of the science It is, of course, a trustworthy picture, perhaps a little over-crowded with detail, but on the whole well proportioned It must be felt that the work in its new form approaches the limit of what can be reasonably compressed within the bounds of a single volume

An excellent account of the ideas associated with an expanding universe is included Here no hesitation is shown in accepting the crude Doppler interpretation of the nebular recession The difficulty presented by the evolutionary time-scale is clearly stated (§ 276) But no mention is made of such possible ways of escape as that suggested by Prof. W D MacMillan in his letter in NATURE of January 16, 1932, p 93. Can it be that the abstruse is now preferred for its own sake to the simple?

Biomathematics being the Principles of Mathematics for Students of Biological Science By Dr W M Feldman Second edition, reset and enlarged Pp xviii + 480 (London · Charles Griffin and Co, Ltd, 1935) 25s net

THE first edition of Dr Feldman's book appeared in 1923 and filled a serious gap in mathematical literature. It has now been out of print for some years, and a new edition is to be warmly welcomed, there being still no other book covering the same field The new edition has been extensively revised and many errors have been eliminated New chapters, on nomography and on the estimation of errors, have been added. The chapter on biometry has been enlarged, and now forms perhaps the best introduction to this important subject for the biologist with only a small knowledge of mathematics

Dr. Feldman's choice of matter is good, his exposition is clear, and many of his biological examples are excellent But it is sincerely to be regretted that he has not sought the criticism of a competent mathematician with regard to the details of his work Incomplete and misleading statements are not uncommon, and most of them could be eliminated without adding to the difficulties of the reader The definition of a convergent series on p 73 is false, as is the statement on p 124 that the graphs of all cubic functions are *S*-shaped Examples of such errors could be multiplied It is to be hoped that a third edition will at some time be called for and that Dr Feldman will remove these blemishes from his valuable book

The Journal of the Institute of Metals Vol 55 (No. 2, 1934) Edited by G Shaw Scott Pp 304 + 17 plates (London Institute of Metals, 1934) 31s 6d net

THIS volume contains eighteen papers presented at the autumn meeting of the Institute of Metals held in Manchester, together with the thirteenth Autumn Lecture The latter, delivered by Dr J L Haughton, took the form of a memorial tribute to the late Dr Walter Rosenhain, and gave an outline of Rosenhain's outstanding contribution to physical metallurgy during his long tenure of office as superintendent of the Metallurgy Department of the National Physical Laboratory

The most outstanding contribution to metallurgical knowledge contained in this volume comes from the recently founded International Tin Research and Development Council Mr. D J. Macnaughtan, the director of research, contributes a paper on "The Improvement of White Bearing Metals for Severe Service", while three other papers sponsored by the same body deal with the behaviour of these alloys under various deformation tests, and present some valuable fundamental data The very full discussion on these four contributions makes this volume particularly valuable as a work of reference on an important group of alloys.

Bergtechnisches Taschenwörterbuch Teil 1. *Englisch–Deutsch* Von Prof W Schulz, Prof H Louis und Bergassessor Goothe Pp 90 (Essen Verlag Gluckauf G m b H, 1934) 4 20 gold marks

THIS is a highly specialised glossary of technical terms used in mining, mining engineering and mining geology. It includes, in addition to technical and scientific terms in general use, special terms peculiar to particular localities This feature should make it particularly useful to German-speaking individuals who wish to read English mining literature, even though the glossary is not free from inaccuracy and lacks some terms which ought to have been included. The complementary German–English part of this handy pocket glossary is promised.

The Industrial Transition in Great Britain

By DR K. G FENELON

DURING the post-War years, important changes have been taking place in the distribution of industries and employment in Great Britain Some of these are well known and the effects are fully appreciated, but concerning others, facile generalisations are frequently made, and this despite the fact that there are few economic problems in which the statistical information available is so abundant

During the eleven years 1923–34, unemployment has fluctuated from somewhat less than 9 per cent to about 23 per cent, whereas in pre-War days unemployment varied between 2½ per cent in the best of times to a little more than 10 per cent in the worst Pre-War unemployment statistics, it is true, are much less adequate than those available to-day, and also certain persons now regarded as unemployed might not have been so regarded before the War, but at any rate it is clear that unemployment is nearly double that of pre-War days It would be a mistake to imagine that the figures of recent years represent a permanent state of unemployment of something like two million workers, because in actual fact unemployment has been spread in each of these years among five or six million workers—that is, about half of the insured population—some suffering little from unemployment and others severely There are two kinds of unemployment, one intermittent, the other prolonged, and it is on those in the latter category that the most tragic consequences of the industrial transition have fallen

How are we to account for the change in the proportion of unemployment since the War? Is it due to the introduction of machinery, and must the inevitable result of scientific progress be that more and more persons will be thrown out of employment? Past experience does not bear this out as inevitable During the nineteenth century —despite enormous technical progress and a great increase in population—unemployment did not steadily become greater The popular view that machines are steadily increasing production and at the same time steadily throwing men out of employment cannot be sustained by reference to statistics of production and employment For example, between 1924 and 1929 the index of production rose from 100 to 111·8 and the employment index increased from 103·8 to 110 5 Nor would it seem, taking industry as a whole, that men are being displaced by women, whatever may be the case in particular industries or occupations. Census returns show that the occupied female population in England and Wales accounted for 30·4 per cent of the total occupied population in 1881, for 29 7 per cent in 1911, for 29 5 per cent in 1921 and for 29 8 per cent in 1931

After the War, a readjustment from war- to peace-time demands had to be effected, and even more difficult has been the problem of reshaping the structure of British industry to meet the decline in exports which has resulted from industrial development in foreign countries, the imposition of all kinds of restrictions on foreign trade, and technological changes such as the displacement of coal by oil fuel especially in shipping

Furthermore, the slowing down of the rate of increase of population in so many countries has tended to shift demand from primary to secondary industries, and it is no longer possible for the basic industries providing ordinary necessaries of life to expand at the same rate as was formerly required by ever-increasing populations These various changes have had severe reactions on British foreign trade, since a disproportionate amount of our industrial resources were engaged in the production of primary commodities

The changed fortunes of the various industries are strikingly brought out by figures for the years 1923–34 relating to the number of insured persons in employment issued by the Ministry of Labour and published in the *Ministry of Labour Gazette* for December last (London H M Stationery Office), from which the following figures have been extracted Since both 1923 and 1934 were years of incipient recovery after a period of depression, a comparison between them would seem to be permissible, provided it is borne in mind that the insured population increased in this period by a little more than 16 per cent

Taking first the depressed industries, those which have suffered a loss in employment of upwards of 10,000 persons each since 1923 are listed in Table 1, fluctuations in employment being shown by means of index numbers for the different years

Coal mining has shown the greatest contraction owing to loss of export markets, economies in the use of fuel and other causes. The iron and steel trades, on the other hand, have made a marked recovery in recent years owing largely to the tariff. Practically all industries show some improvement in 1934, with the exception of cart and carriage building, which has suffered from the continued development of motor transport

In marked contrast are the expanding industries, the more important of which, from the point of

view of additional employment afforded, are set out in Table 2

Altogether, the expanding industries have given employment to the equivalent of all those displaced since 1923 from the declining industries and have provided employment for nearly a million persons in addition In these industries, many of rather to its success in attracting new industries Moreover, its typical industries are luxury trades or light industries which have been less hard hit than the old-established industries of the north.

The economic transition which is slowly working itself out becomes more apparent if the expanding industries are classified in groups as follows

Table 1

Contracting Industries Great Britain and Northern Ireland

Industry	Number Employed		Index Number of Employment (1923 = 100)*			
	June 1923 Aged 16 and over (Thousands)	June 1934 Aged 16-64 (Thousands)	1925	1929	1932	1934

London, 94 in the north-west of England and 63 in the Midlands In the same year, there were 95 factory extensions, while 409 factories were closed down Only three of the new factories represented transfers from the north to the south, and of these, two were aircraft factories The growing industrialisation of the south of England has been due not to the transfer of factories from the north, but industries and the manufacture of specialised products.

The changes in industrial structure revealed by the statistics reflect deep-seated economic and social changes in the life of the community As examples we may refer to housing, the great development of which is revealed by the fact that between 1923 and 1933 inclusive, some 1,800,000

houses have been built in England and Wales. The spread of leisure has led to a marked expansion in entertainment and sport, while changes in social and domestic habits account for the development of bus travel, the growth of restaurant and hotel businesses and the expansion of laundry and similar trades which provide services formerly carried on in the home

The new manufacturing industries are much more numerous than is commonly supposed, though the development of many of them is hidden under the generic names in the Ministry of Labour's list In the development of new industries, or the recent expansion of the old-established trades, scientific discovery or the application of science has played an important part. A long list of such products could be given, but it must suffice to mention rayon; aircraft; motor-cars, electric cables, lamps, motors and apparatus, radio, neon signs, photo-electric apparatus, pharmaceutical chemicals; detergents, synthetic resins and other plastic materials, cinematograph films, refrigerators; solid carbon dioxide, chromium plating, cellulose products, and canned foods Indeed, the extent to which scientific research is transforming methods of production is seldom fully realised, and, as was stated in a report of the Department of Scientific and Industrial Research, "in nearly every industry to-day, movements are on foot to apply old materials to new uses or to discover uses for new products"

In rayon, the relation of science to industry is conspicuously close, and this industry has made rapid progress in those countries which possessed a well-developed chemical industry. Other thriving new-comers are the plastic industries, the products of which are now extensively utilised not only for accessories of all kinds, but also in the manufacture of silent gear wheels and in chemical engineering, where their resistance to boiling acids and corrosive fumes are of value Canning is another industry which has recently made rapid progress in Great Britain, expanding its production from about 2–3 million cans in 1925 to more than 100 million cans in 1931 Special problems had to be overcome on account of the high acid content of British fruit, and the difficulties in preserving the colour and flavour. Many ingenious machines have been constructed by British manufacturers for this industry

In connexion with the building-up of new export trades, scientific applications are an essential asset Specialised products, combining high quality with skilled workmanship, are frequently assured of a ready sale overseas, such as has been achieved by British manufacturers of light aeroplanes, motor-cars and electrical apparatus An interesting illustration of the advantages of scientific specialisation in export industries is the almost exclusive utilisation of British photographic and projection lenses in the film studios of Hollywood.

The Professors of the Royal Institution

By THOMAS MARTIN

BY the election on May 7 of Sir James Jeans as professor of astronomy in the Royal Institution, its members have exercised a privilege which has not been used since 1863 Faraday was then the Fullerian professor of chemistry, but he was in his declining years, and Dr (afterwards Sir Edward) Frankland was elected to a separate professorship of chemistry. Frankland discharged the duties until shortly after Faraday's death in 1867, when Odling became the Fullerian professor and Frankland's professorship was allowed to lapse. The other 'elected' professorship in the Institution at the time, that of natural philosophy, had been established ten years earlier, and was not so short-lived. It was created for John Tyndall when he went to the Institution in 1853, to become the friend and colleague of Faraday in the last fourteen years of his life; and it has continued by election and re-election to the present day.

Lectures on scientific subjects, to be given in a lecture room with the most up-to-date facilities for experiment and demonstration, were a part of the original scheme drawn up in 1799 by the founder, Benjamin Thompson, Count Rumford; and when Rumford's proposals were adopted and the Royal Institution of Great Britain came into existence, the "teaching by courses of philosophical lectures and experiments the application of science to the common purposes of life" was recited as one of its objects in the Royal Charter granted by King George III. The lecture room was constructed, under Rumford's personal supervision, at the house which had been purchased in Albemarle Street, and the procedure to be followed in appointing professors and lecturers was laid down in the by-laws given to the new Institution. The professors were to be elected annually by ballot, and a new professorship could be established at any time, by resolution proposed by fifteen members, which must be carried at one general monthly meeting and confirmed at the next.

The first of the Royal Institution professors was Dr. Thomas Garnett Trained as a physician, Garnett had already established a reputation in his profession and as lecturer at Anderson's Institution in Glasgow when, in 1799, he accepted the invitation conveyed by Rumford to join the new institution in London He was elected professor of natural philosophy and chemistry, and on his arrival in December, entered with enthusiasm on his varied duties, but his tenure was not destined to be a long one After some initial success with his London audience, he found himself handicapped by ill-health, by a certain diffidence as to his own powers, and by his north country accent Moreover, he worked under the critical eye of Count Rumford, who lived at the Institution at the time, and personally supervised every detail of its activities It is not surprising that causes of difference appeared In Rumford's view the lectures given by the professors were those they were requested to give, and the experiments they made were those they were directed to make, by the Managers and the various committees The work of the professors was but a part of the whole The Institution, with its library, its workshops, its school for training workmen and mechanics, its repository for models and inventions, was formed for "diffusing the knowledge and facilitating the general introduction of useful mechanical inventions and improvements". It was a part of the philanthropical activity of the day, an attempt to bring to the working classes a knowledge of the useful applications of science.

Garnett found the difficulties of his position too great for him; and resigned his professorship in June 1801. Before he left, a lecturer in chemistry was appointed to share the work Rumford, writing of the new appointment to his daughter Sarah, in America, said · "We have found a nice able man for his place as lecturer, Humphry Davy"; and in March 1801, Davy was brought from Dr Beddoes' Pneumatic Institution at Bristol, the place of his experiments on nitrous oxide, to begin the career of exposition and research which was to bring fame to himself and to the Institution in which he worked

To begin with, Davy, then only twenty-three years of age, was in a junior position, and when Garnett resigned, a new professor of natural philosophy was elected, the Quaker physicist, physician and Egyptologist, Thomas Young Thus, almost at the outset, the Royal Institution had associated in its work two men, Young and Davy, whose names are among the greatest in English science Young was engaged at the time on those papers on the theory of light and colours, in which he states his conclusion that "radiant light consists in undulations of the luminiferous ether" and explains the phenomena of interference by means of the wave theory. Although Young was, according to Davy, a most amiable and good-tempered man, his somewhat severe and didactic manner as a lecturer gave him no great success with popular audiences He held his professorship for only two years, and then retired, to devote himself to his medical work and other pursuits

Davy became the professor of chemistry, and his work, more than that of any other man, determined the lines on which the Royal Institution was to develop In the lecture theatre, he possessed all those qualities which Young lacked He infected his audiences with his own enthusiasm. Such was the charm of his personality and the eloquence of his discourse that he made his scientific lectures one of the fashionable amusements of London. Interest in him was heightened by the discoveries he soon began to make in the laboratory, in particular, those on chemical decomposition by means of the electric current, which enabled him to prepare sodium, potassium and other elements, until then unrecognised Later came the Continental tour, with Faraday as his assistant, and the discovery of iodine in Paris, and, on his return to the Institution, the invention of the wire gauze safety lamp for miners

Davy's activities in the laboratory and the lecture theatre established the traditions which have ever since characterised the work of the Royal Institution, of research inspired and largely carried on by the resident professor, and exposition, aided by all the resources of experiment, in terms suited to the layman as well as to the man of science. The Institution continued to attract the "higher ranks of society" whom the early Managers had wished to interest in it as a missionary enterprise depending on their support, but it became also a scientific centre, a place of original research in the problems of pure science which interested the professors Its scope had become at once wider and narrower than the original intention. The training of mechanics, the construction of kitchens, of models, and other measures for introducing scientific improvements for the benefit of the lower classes, were dropped; although the Managers responsible for the change consoled themselves with the thought that the poor must surely benefit indirectly from the useful activities to which the upper classes of the metropolis could now devote their leisure Count Rumford, soon after Davy's arrival, had fallen out with the other Managers, and gone to live in Paris, whence he grumbled by letter to Sir Joseph Banks at the change of plan in the institution he had founded.

Davy continued in his professorship until 1813. In the previous year he had been knighted by the

Prince Regent, and now, on his marriage to the wealthy Mrs. Apreece, went to live away from Albemarle Street. He was made honorary professor, and although he gave no lectures, continued to work in the laboratories for some years after. Early in this year he did one of his greatest services to the Institution by engaging Michael Faraday, a bookbinder's apprentice who had shown some interest in science, as his assistant

The new assistant soon proved his worth, and began the progress which made him eventually Davy's successor, and the connexion with the Royal Institution which was to extend over fifty-four years His duties were to assist Sir Humphry in his researches and to attend on the other professor and lecturers W T. Brande had taken Davy's place as professor of chemistry, and Faraday's first opportunity of demonstrating his powers as a lecturer in the Institution came some years later, when he was called upon to take Brande's place in an emergency.

Faraday's training in his years as Davy's assistant made of him a good chemist and a skilled experimenter. His first attempts at research of his own were naturally on chemical problems, and early successes were the discovery of new compounds, including in particular "bicarburet of hydrogen" (benzene) The news of Oersted's experiments at Copenhagen set Davy to work on electromagnetism, and stimulated scientific interest all over Europe Faraday, following the developments closely (since his tour in 1813–15 in France and Italy with Davy he knew some of the men whose papers he was reading), had by 1821 made his own contribution to the subject by his discovery of the electro-magnetic rotations It was the beginning of his electrical researches.

The audiences in the lecture theatre discovered, too, that the young assistant had powers of his own Brande, who retained his professorship until 1852, was not, it seems, an inspiring lecturer Faraday, whose methods were less impulsive than those of Davy, had fluency and address at the lecture table, with a genius for apt experiment, and as the years went by he outshone his former master in his ability to fill the lecture theatre and stir in his audience some reflection of his personal enthusiasm.

In 1833 a new professorship was established, of a different kind from the others John Fuller, a wealthy landowner and member of Parliament, made a gift of money for the endowment of what was called the Fullerian professorship of chemistry, the appointments to which were to be made by the Committee of Managers, and were not subject to annual re-election by the members. Faraday became the first Fullerian professor, and occupied the chair until his death in 1867.

It is difficult to speak of Faraday's professorship in a few words It may be said that for nearly forty years, from the moment when in 1825 he became Director of the Laboratory following Davy's statement that "he considered the talents and services of Mr Faraday, assistant in the laboratory, entitled to some mark of approbation from the Managers", he carried the Institution on his shoulders. He upheld and extended the traditions which Davy had originated Two of the characteristic activities, the Friday evening discourses and the Christmas juvenile lectures, owe their inception almost entirely to Faraday To his audiences, he was without a rival in his mastery of the arts of exposition and demonstration by experiment His discovery of electromagnetic induction and his researches in electro-chemistry and electrostatics made him the first man of science of his age

Fuller had endowed a second professorship in 1834, of physiology Unlike that of chemistry, the Fullerian professorship of physiology was to be held for a fixed term of three years. P M Roget was the first professor, and he has been followed by a line of distinguished men The list includes the names of T H Huxley, Sir Richard Owen, Sir Michael Foster, Sir Edwin Ray Lankester, and more recently Sir Charles Sherrington, Sir Arthur Keith and Sir Grafton Elliot-Smith

Tyndall owed his connexion with the Institution to the favourable impression he made when, as a young physicist of promise, after a period of work in Germany, he was invited to give a Friday evening discourse His election in May 1853 as professor of natural philosophy followed, and the later years at least of his professorship must be within the memory of many now living. It is said that he and Faraday worked together in the closest harmony, and that the relations of the older to the younger man resembled those of a father to a son On Faraday's death in 1867, Tyndall followed him as the resident professor, and lived at the Institution until his retirement in 1887 He did valuable experimental work on the radiation and absorption of heat by gases and vapours, and his discovery that bacteria will not breed in dust-free air has been of great importance; his work on sound was done as scientific adviser to the Trinity House, in which office he succeeded Faraday He is perhaps best remembered as an expositor, for his animation and lucidity as a lecturer and for the felicity of his style as a popular writer on science.

William Odling, who succeeded Faraday as Fullerian professor of chemistry, resigned in 1873, after five years. He was followed, for another period of five years, by Dr J. H. Gladstone, who in turn was succeeded, in 1877, by Professor

(afterwards Sir James) Dewar This was the beginning of another long tenure, for Dewar held the professorship for forty-six years, until his death in 1923, and from 1887, after Tyndall's retirement, he lived at the Institution as the resident professor

Dewar's matchless skill as an experimenter, the fame of his researches, and of his Friday evening lectures with their carefully prepared and rehearsed demonstrations, are well known and remembered In the Royal Institution laboratories, with apparatus often on an engineering scale, he liquefied the so-called permanent gases, and produced them for the first time—oxygen, hydrogen and air—in quantities sufficient for experiments on the properties of materials at the very low temperatures he reached, he invented, as a container for the cooled gases, the 'thermos' or Dewar flask, and he developed the method, of great technical importance, of making high vacua by using the great absorbing power for gases of charcoal cooled in liquid air These are but the best known among his achievements To quote the words of a distinguished contemporary · "He was in no way less successful than his predecessors, Young, Davy and Faraday, in adding to the reputation these pioneers created for the Royal Institution as a centre of scientific discovery and invention" It may be added that the recent lamented death of Lady Dewar is a reminder that not the least important of the Dewars' services to science was given as host and hostess in their house at the Institution

Since Tyndall, three physicists of great distinction have held the professorship of natural philosophy who have also been, in turn, the Cavendish professor of physics at Cambridge. The late Lord Rayleigh, soon after his retirement from Cambridge, accepted the invitation to the chair at the Royal Institution, and held it until 1905, when he was succeeded by Sir J J Thomson The present professor, Lord Rutherford, took up the duties in 1921 The rules prescribed at the beginning of the Institution for the election of professors are still followed, and thus it is that Lord Rutherford, as an 'elected' professor, must seek the suffrages of the members once a year, while Dewar's successor in the endowed Fullerian professorship of chemistry, the present resident professor, Sir William Bragg, does not do so

Obituary

MR. C F CROSS, F.R.S

MR CHARLES FREDERICK CROSS, who died in his eightieth year on April 15 at Hove, where he had lived in retirement for some years, left us indebted to him for a life devoted to a most difficult and unpromising branch of chemical research, rewarded by an epoch-making discovery, which is represented in Great Britain to-day by an artificial silk industry with a market capitalisation of more than £70,000,000 He was educated at King's College, London, the University of Zurich and Owens College, Manchester. In 1879, his work on the cellulose group commenced with a study of jute, and later, in association with Mr. E J. Bevan and Mr. C. Beadle, he started the well-known business of Cross and Bevan, consultants to the paper trade.

It is difficult to estimate the number of papers on the chemistry of cellulose published by Cross and his collaborators; these date from 1880 until 1920, and appeared in the *Journal of the Chemical Society*, *Journal of the Society of Dyers and Colourists*, *Berichte*, *Phil. Mag*, *Bull. Soc. Chim.*, and many less-known publications. In these and in his textbooks, he has left us a mine of information and, as Prof. H. E. Armstrong has pointed out, the mystic character of some of his explanations must be ascribed to the intangible nature of his subject Fulfilling the functions that it does in the plant, cellulose is on the border-line of living substances itself, and is liable to alter with every change in conditions to which it is subjected. His suggestion that it is an 'amphoteric electrolyte' hides a complexity of behaviour that has not been much illuminated by more modern advances in chemical language

In 1892, Cross discovered that, by virtue of the alcoholic properties of cellulose, a soluble xanthate could be obtained on reaction with caustic soda and carbon disulphide Working at Kew with Stearn and Topham, who were at first interested in the application of the new discovery to the manufacture of electric lamp filaments, the practical difficulties in spinning a continuous textile fibre were overcome, and the viscose silk industry was born.

At first, the solution of cellulose xanthate was expressed through a number of fine holes into a solution of ammonium sulphate, and the use of an acid bath, which resulted in the formation of a cellulose thread in one operation, was not arrived at until years later The reception of the thread in a centrifugal box, which collected, drained and twisted it in one operation, due to Topham, has remained the standard practice up to the present day. In 1905, manufacture was started by the firm of Courtauld at Coventry, and the writer, then in charge of the chemical department, has a lively recollection of Cross, who took a great interest in the new venture, with his interesting suggestions, cheery sporting manner, wide culture and artistic interests.

Recognition of the value of Cross's work came later; in 1917 he was elected fellow of the Royal Society, in 1916 he received the medal of the Society of

Chemical Industry and in 1918 the research medal of the Worshipful Company of Dyers He was elected president of the Society of Dyers and Colourists in 1918, and received the Perkin Medal in 1923.

SIDNEY S NAPPER

COLONEL W. G. KING, C I E.

COLONEL WALTER GAWEN KING, late of the Indian Medical Service, died at his home at Hendon on April 4 at the age of eighty-three years He graduated M B and C M in 1873 at the University of Aberdeen, where he also took the D.P H in 1888 Soon after qualifying, and before his twenty-third birthday, he entered the Indian Medical Service, in which he passed the next thirty-six years of his life

On reaching India in 1874, King was posted to the Madras Presidency and, after two years military service with an Indian regiment, was transferred to civil employment, in which he quickly distinguished himself for his active work in the great famine of 1876–77 and the terribly severe cholera epidemic which accompanied it. This experience made him decide to devote his life to preventive medicine, and it is chiefly for the remarkable work which he did in this sphere during a succession of appointments as inspector of vaccination, deputy sanitary commissioner and sanitary commissioner of the Madras Presidency and later as inspector general of civil hospitals and sanitary commissioner of Burma, that his name will go down to posterity as the leading pioneer of public health in southern India.

King's great merit was that at a time when smallpox, cholera and malaria were the three chief scourges of India, and when the scientific world knew nothing of the causes of cholera or malaria, and, therefore, knew nothing of their prevention, he set to work to organise scientific investigations for the benefit of public health and did not pause in the task until the goal he aimed at was attained At that time, bacteriology was in its youth and the modern sciences of tropical protozoology, helminthology and medical entomology were in their earliest infancy or were as yet unborn. The malaria parasite was not discovered until 1881, and the fact that it is spread by mosquitoes not until 1897 The cholera vibrio was not discovered until 1883 Smallpox, however, could be controlled because a prophylactic was already available and the only problem to be solved was how best it could be applied In Madras, vaccination with animal lymph instead of with human lymph was successfully established in 1880–81, but more than ten years were to elapse before a satisfactory method of preserving the lymph under tropical conditions was devised. King's well-planned and carefully controlled laboratory experiments conducted in 1890 to ascertain the relative merits of lanoline and vaseline as a preserving medium may be cited as a good example of the immediate utilitarian researches to which he devoted what time he could spare from his many other duties.

Later when, at his repeated request, the Government of Madras established a central animal vaccine lymph depot for the Presidency, King quickly extended its work to include bacteriological diagnosis and other expert assistance to civil surgeons and medical practitioners, and finally made arrangements for the preparation of prophylactic and curative sera and vaccines and for the prosecution of original protozoological and entomological research of direct importance to tropical medicine In 1903, when the main buildings of the bacteriological section were completed, the Institute became the provincial laboratory for the Madras Presidency and was named, in recognition of King's services to public health and the efforts he had made to bring it into existence, "The King Institute of Preventive Medicine". In the general scheme for laboratories which had been submitted to the Government of India by the late Surgeon-General Harvey in 1899 it was the third to be established, being preceded only by the Haffkine Institute at Parel, Bombay (1896-99), and the Pasteur Institute of India at Kasauli (1900)

After his retirement, Colonel King served in the War from 1916 as A D M S Western Command and later was consultant at the Tropical Diseases Clinic, Ministry of Pensions, and lecturer in applied hygiene in the tropics at King's College, London He had the satisfaction, too, of seeing the institute in India which he founded grow gradually until its activities covered a wider field in the practical application of scientific knowledge to routine medical and public health needs than those of any other laboratory in India

S P J.

PROF R CARR BOSANQUET

WE regret to record the death of Prof R Carr Bosanquet, formerly professor of classical archæology in the University of Liverpool, which took place on April 21 in a nursing home at Newcastle at the age of sixty-three years.

Robert Carr Bosanquet was the son of Mr Charles Bertie Pulleine Bosanquet, and was born at Rock Hall, near Alnwick, on June 7, 1871 He was educated at Eton, where he was Newcastle Scholar in 1890 and edited the *Eton College Chronicle*, and at Trinity College, Cambridge, of which foundation he was a scholar. He took firsts in both parts of the Classical Tripos, and was elected to a Craven travelling studentship, which he held from 1895 until 1897.

Bosanquet's interest in archæology was first aroused by the antiquities of Roman Britain which lay within striking distance of his home. In 1897 he excavated Housesteads (Borcovicium) on the Roman Wall. In the following year he was appointed assistant director of the British School of Archæology in Athens, later succeeding to the office of director In 1906 he was elected to the chair of classical archæology in the University of Liverpool, which he occupied until 1920, when he retired in order to devote himself to the management of the estate which he had inherited from his father, giving such time as this allowed him to further research in the archæology of Roman Britain He was a member of the Royal Commission on Ancient Monuments in Wales, a position for which his extensive knowledge

of Welsh antiquities peculiarly fitted him, and of the advisory board on Ancient Monuments in England.

As an archæologist, Bosanquet had a high reputation among the expert, but neither his achievement nor its qualities was such as to lend itself to building up wide popular recognition. He was one of the group who, following closely in the footsteps of Sir Arthur Evans, at the turn of the century and in the years immediately following placed British archæology in the field in a commanding position in international scholarship, and Bosanquet was one of those who helped to extend that meticulous care in excavation, characteristic of field work in the Mediterranean, to the study of Romano-British sites. As director of the British School at Athens he worked in Crete, where he was responsible for the excavation of the archæologically valuable site of Palækastro, at Phylakopi and in Laconia, where he initiated the important excavation of the temple of Artemis Orthia. He was the author of "Borcovicium" (1904) and part author of "Phylakopi" (1904), but the principal part of his contribution to archæological literature appears in the *Annual* of the British School, the *Journal of Hellenic Studies* and other periodicals. His work was accurate and precise, and informed with wide knowledge. It showed all the polished definition to be expected of a finished scholar.

PROF. E. POULSSON

WITH the death on March 19, at the age of seventy-seven years, of Prof. E. Poulsson, Norway has lost one of her foremost scientific workers. He was chiefly known on account of his work in connexion with the fat-soluble vitamins as they are found in cod liver oil. In innumerable papers he has shown that the female organism in the sexually mature years has a greater vitamin reserve than the male. Similarly, he has proved that the chondropteryginous fishes—in contradistinction to the osseous—are only endowed with negligible quantities of vitamin D, a substance which they manifestly do not require as their framework is only to a very limited extent composed of lime compounds.

Prof. Poulsson was deeply interested in the importance of cod liver vitamins to the growing organism. He showed in several papers the part played by these vitamins in relation to the unborn individual and in habitual abortion, and he did much to extend our knowledge of the medicinal importance of cod liver oil. One of the most important of Prof. Poulsson's contributions to the cause of vitamin research is undoubtedly his well-known method for the quantitative determination of vitamin D. By this method vitamin D was determined in Oslo-units and these were in use in many countries until the international units were introduced. As Norway's representative, Prof. Poulsson was a member of the League of Nations Vitamin Standardisation Committee.

In the sphere of pharmacology Prof. Poulsson was particularly well known. His textbook on this subject is used in many parts of the world in English, Spanish and German translations, and ten editions have been published. The book successfully combines theoretical thoroughness with practical insight. Written in an easy style, it is an invaluable aid for the ordinary practitioner.

Prof. Poulsson was born in 1858. He became a doctor of medicine in 1892, studied chemistry under Fresenius at Wiesbaden and pharmacology under Schmiedeberg at Strasbourg. He was professor of pharmacology at the University of Oslo in 1895–1928. As professor emeritus from 1928 until his death, he was director of the State Vitamin Institute. His charm and directness of manner gained him many friends both at home and abroad.

OTTAR RYGH.

THE death of the eminent American medical historian Lieut.-Colonel Fielding Hudson Garrison at the age of seventy-four years took place on April 18 in the Johns Hopkins Hospital. He was the author of an introduction to the "History of Medicine" (fourth edition, 1929) and numerous articles on the history of medicine, as well as co-editor for some years of the *Index Medicus, Quarterly Cumulative Index*, and *Annals of Medical History*, consulting librarian to the New York Academy of Medicine and librarian to the Welch Medical Library at Johns Hopkins University.

WE regret to announce the death on April 9 of Dr. Edouard Antoine Jeanselme at the age of seventy-four years; he was formerly professor of diseases of the skin and syphilis in the Paris faculty of medicine, author of an authoritative work on leprosy (1934) and editor of a treatise on syphilis in several volumes in course of publication.

WE regret to announce the following deaths:

Prof. J. E. Guthrie, professor of zoology in Iowa State College, on April 16, aged sixty-three years.

Prof. T. C. Hopkins, formerly professor of geology in Syracuse University, known for his work on building stones, clays and iron ores, on April 3, aged seventy-three years.

Prof. George E. Johnson, professor of zoology in the Kansas State College, an authority on the physiology of hibernation, on March 18, aged forty-five years.

Prof. Wilhelm Kolle, director of the State Institute for Experimental Therapy and of the Georg-Speyer-Haus Chemo-Therapeutical Institute, Frankfurt, on May 10, aged sixty-four years.

Prof. J. L. R. Morgan, professor of physical chemistry in Columbia University, on April 12, aged sixty-two years.

Prof. E. B. Skinner, emeritus professor of mathematics in the University of Wisconsin, on April 3, aged seventy-one years.

Dr. H. H. Thomas, F.R.S., petrographer to H.M. Geological Survey, on May 12, aged fifty-nine years.

Sir James Walker, F.R.S., emeritus professor of chemistry in the University of Edinburgh, on May 6, aged seventy-two years.

Magneto-Optic Rotation

THE subject of the influence of magnetism on light has again been coming into experimental prominence, combined, however, with confusion on the side of theory, and a brief exposition of some considerations which I have treated more privately more than once may be to the public advantage

One may recall that this influence was one of the grand discoveries of Faraday, guided by his own instincts, to be classed as regards mode with the Einsteinian assertion of the relation of gravitation to radiation and its spectrum It was eagerly seized upon by Lord Kelvin, with his engineering instincts, as sheer demonstration that in magnetism there is involved dynamical spin round its axis The electron theory permitted this spin due to magnetisation to be calculated, and conversely and the experiments that have been going on (Barnett, de Haas and Einstein, Sucksmith, and others) have verified the computed result except for a factor which seems to be exactly 2, and demands a more refined theory scarcely yet suitably envisaged

The subject, thus indicated as being at the very foundations of physical science, occupied several chapters, largely speculative, in the second volume of Maxwell's "Electricity and Magnetism" (a book nowhere really much known except in Great Britain and America) which appeared only about sixty years ago, thus being not quite so old as the "Principia". But formulæ thereby suggested, mainly on a vortical basis, for the magneto-optic rotation were passed in review, in relation to such experimental data as then existed, satisfying Verdet's law that the effect was roughly governed as a main factor by the inverse square of the wave-length Afterwards a formula was advanced by the physicist, P Drude, in his "Treatise on Optics", familiar in an American translation, but this appears to be restricted to the very different problem of *natural rotation*, introduced optical dispersion into the result, giving the optical rotation R in terms of the wave length λ by a formula, containing a term for each spectral band λ_r in the form

$$R = \Sigma \frac{A_r}{\lambda^2 - \lambda_r^2},$$

in fact, of the same type as the formula for refraction, $\mu^2 - 1$, in a gas

About 1897 by a happy chance an expression was hit upon for the magnetic case by Henri Becquerel, the discoverer of radioactivity (with whom I was acquainted mainly through Lord Kelvin), which made R equal to the very simple form $e/2mC\ \lambda\, d\mu/d\lambda$, where e is the electron charge and C the velocity of light This has been abundantly tested and comes right except for a factor which (according to Prof C G Darwin) is usually about 3/5 Thus, generally R is as the gradient of μ To obtain a formula, for a gas

$$\mu^2 - 1 = \Sigma \frac{B_r}{\lambda^2 - \lambda_r^2},$$

giving

$$\mu R = \frac{e}{2mC} \frac{-2B_r\lambda^2}{(\lambda^2 - \lambda_r^2)^2}$$

close to each absorption band where λ is nearly equal to λ_r This of course makes R great, but of the same sign on both sides of the band (in agreement with observations by Macaluso and Corbino at Palermo), whereas the formula of Drude makes the natural rotation of different signs, a result capable of test I remember this contrast, because a hasty assertion by slip of pen to the contrary in "Aether and Matter" (p 353) was soon challenged by my friend Prof R W Wood, of Baltimore, who was experimenting on the subject, to whom therefore might be said to belong the actual type of inappropriateness of the Drude formula This happens to be of peculiar interest in connexion with the remarks in this and more general regards, on R W Wood's "Physical Optics", made in NATURE of March 2, p 325, which suggested the present note as a useful antidote

The Becquerel magnetic formula as above may be written

$$\mu R = \frac{e}{mC} \Sigma \left\{ -\frac{B_r}{\lambda^2 - \lambda_r^2} - \frac{B_r\lambda_r^2}{(\lambda^2 - \lambda_r^2)^2} \right\},$$

the ratio of the second term to the first being $\lambda_r^2/(\lambda^2 - \lambda_r^2)$ thus if λ_r is very small compared with λ the first term, of Drude type, suffices, so that R_r could be regarded as due to one abnormally potent band of absorption in the remote ultra-violet, whereas near the band it is the other term that prevails

The coefficient in this Becquerel formula applies for a gas For a dense substance the Lorentz expression $3(\mu^2 - 1)/(\mu^2 + 2)$ must take the place of $(\mu^2 - 1)$ on the left, and differentiation gives a different factor in R which would make a very considerable difference near the band of absorption.

The necessary references, those available here remote from a library, are *Trans Camb Phil. Soc*, Stokes Commemoration Vol (1900) § 7, as reprinted in the writer's "Collected Papers", vol 2, p 179, which gives a reference to a comparison with records of experiments drawn up by Prof C G Darwin, *Proc Roy Soc.* (1927): and also my 'Aether and Matter' (1900), p 353, where §§133–8 connect the trend of rotation with that of K or μ^2

A suggestion of more constructive character is led up to by the assertion of the 'obsoleteness of damping' for the discussion of refractive dispersion and absorption. It is not difficult formally to include a frictional term in the Maxwell-Sellmeier formula for dispersion: if one remembers aright, Maxwell had done so. In his book "Magneto-Optik", the eminent Göttingen physicist Woldemar Voigt had doubtless included both magnetic and frictional terms in his scheme of equations, though in a way that would now be regarded as scarcely more than illustrative. His resulting triple division of the absorption line, in fact the inverse form of the simplest type of Zeeman effect, would thus be influenced as regards positions and intensities by the damping which need not be negligible for transmission through dense media. Hitherto it appears to have been position and polarisation of the components that have been mainly treated. But now astronomers have in their hands delicate instruments that can trace the intensity of impression across the broadened line on the photograph with precision. If they can provide data from the Zeeman broadening, this would appear to go some way towards doubling the material with which specialists have to deal in this intricate but promising domain.

Concentration of Artificially Produced Radio-elements by an Electric Field

ONE of the best methods of collecting radioelements free from any inactive material is the application of an electric field, either to the gaseous or liquid phase. Well-known examples of the former process are the collection of the 'active deposits' produced by the three emanations; of the latter, the electrolytic deposition of these and other isotopes of lead, bismuth and polonium. It seemed worth while to investigate whether an electric field might also be of help in concentrating the newly discovered artificial radioelements. Especially interesting is the question as to their possible charge when produced in gases by fast and slow neutrons.

In our experiments the neutrons were obtained from 30 millicuries of radiothorium mixed with powdered beryllium, and slowed down by water. The field was applied by using a silver flask with an inner electrode, usually in the form of a platinum wire. Each experiment was performed with this electrode charged to +1300 volts and 1300 volts alternately (about 300 volt/cm). For various reasons, arsenic seemed one of the most suitable elements and consequently most of the experiments have been done with arsine. As is well known, this compound tends to react on the walls, leaving a deposit of arsenic, but by purifying the gas carefully we were able to suppress its spontaneous decomposition almost completely. As Fermi and his co-workers have shown[1], slow neutrons produce the change $As^{75} + n^1 \rightarrow As^{76}$, the latter losing its activity with a half-value period of one day.

Without a field no activity whatever was found on the wire, even when this had acquired a visible coating of arsenic. Application of the field, however, in either direction, resulted in the collection on the electrode of up to 30 per cent of the total activity produced by the neutrons, together with only about 0·02 per cent of the total inactive arsenic, the concentration factor (that is, the change in the ratio As^{76}/As^{75}) being in this case 1,500.

From these experiments it appears that any characteristic charge which may be imparted to the active arsenic isotope at the moment of its formation is not retained; it is probable that solid arsenic particles are formed[2], which acquire a charge by catching the ions present in the gas. The failure of Fermi and his co-workers to obtain an appreciable improvement in the yield by applying a field to the vapour of methyl and ethyl iodide[3] was probably due to the high vapour pressure of iodine, or to exchange processes. We varied the experimental conditions in different ways: by changing the pressure of the arsine and the metal of the electrode, by adding hydrogen or water vapour, and by increasing the ionisation by an additional radiation. Even when by these variations the chemical decomposition was so much accelerated as to cause the deposition of a layer of arsenic on the electrode of a thickness of about 10^{-4} cm, the yield of the active isotope was only very slightly increased. On the other hand, we were able to collect up to 20 per cent of the active isotope on either electrode without any visible layer of arsenic. In such experiments the concentration factor was certainly greater than 20,000.

We think that this method of concentration by an electric field will be of practical use whenever very thin layers of the new radioelements are required. There is no reason why it should not be applied to the collection of the non-isotopic radioactive atoms produced by fast neutrons. Here, in the distribution of the charges, a recoil effect will possibly be found. The method will also be extended to liquid systems, to which preliminary experiments, in which Dr E Gluckauf has assisted us, have shown it to be applicable.

Nature of Cosmic Rays

IT seems quite certain that it is not possible to explain all the effects of cosmic rays by means of a single corpuscular component. On the other hand, the results of the direct measurements of the energy of the rays, by their curvature in a magnetic field, are difficult to reconcile with the existence of any simple relation between their energy and penetrating power. I want, therefore, to suggest a dualistic theory of the cosmic rays, based on the existence of two primary components, both of great energy, but which are absorbed very differently by matter[1].

The primary corpuscular rays, on arrival at the top of the atmosphere, are supposed to be formed of a mixture of electrons (perhaps of both signs) and of heavy particles, such as protons. These particles, which we may call the M and the D groups, have energies of the same order, which at a latitude of 45°, lie between 4×10^9 and 10^{11} electron volts. There must be a large number of particles of group M to

one of group D In traversing the atmosphere, they suffer both a slow loss of energy and also large collision losses due to the formation of secondary electrons and photons The coefficients of absorption for the electrons are about 5×10^{-3} cm ^{2}/gm and for the protons $0 \cdot 7 \times 10^{-3}$ cm ^{2}/gm In light elements, the absorption of both components is nearly proportional to the density of the absorbing material The greater the absorbing material traversed, the stronger is the component D relative to M, until, under 20 metres of water below the top of the atmosphere, M has nearly disappeared[1] In dense matter of low atomic weight (water, earth, etc), the formation of secondaries (electrons and photons) at close intervals determines the creation of multiple rays capable of producing coincidences in counters placed out of line.

If the two groups of rays traverse heavy elements such as lead, they behave quite differently The absorption of the D particles is proportional to the mass of matter traversed, and is accompanied by the formation of secondaries and perhaps of showers, as in light elements The M particles, on the other hand, suffer very intense absorption due to the emission of radiation during nuclear collisions The photons produced have a short path in lead and give rise to numerous electron-positron pairs This is the origin of the typical shower, such as determines the typical maximum of Rossi's curve.

The concentrated type of shower can be attributed to the occurrence of an absorption process in the interior of a piece of heavy material, and the diffused shower to an absorption process occurring near a free surface, so that the ejected photons spread out and are then absorbed by surrounding dense objects After the decrease which follows the maximum of the curve of showers, that is after 6 cm of lead, only component D remains, and the remaining multiple coincidences are to be attributed to secondary effects of this component, with possibly a few showers Rossi's curve is really due to the superposition of the multiple secondary effects of M and of D If one works at a place where M has disappeared, no typical maximum is found, but only the effect of D

The absorption of the two groups of particles can be studied by the interposition of screens between the counters as arranged vertically for counting coincidences. The curves so obtained for lead show an initial rapid decrease due to the absorption of the secondary rays, and of group M, and then after 10 cm. a slow decrease due to D. With matter of lower atomic weight, such as copper, one obtains different curves, in which the rapid decrease due to the absorption of the secondaries is followed by that of group M, and after 20 cm by the slow decrease due to D

Actually the collision absorption, which increases with the atomic number of the atoms forming the screen, is much smaller in copper, corresponding to the smaller production of showers One can show by absorption in lead that after traversing 8 cm. of copper, there still remains a considerable part of M; the rapid decrease which additional lead then produces is the same as that at the start of the absorption curve in lead. After M has disappeared, the component D continues alone, with the same mass absorption coefficient in all materials.

Cosmic Rays and Novæ

IN dealing with this subject in a recent letter[1], I most unfortunately overlooked some recent work of W. Baade and F Zwicky[2] These authors have advanced the highly interesting theory that cosmic rays have their origin in outbursts of *super*-novæ in extra-galactic nebulæ, and did so a year before the appearance of Nova Herculis prompted a search for a possible connexion between cosmic rays and nova phenomena in general Super novæ are thought to occur in each nebula about once in a thousand years, and, from certain hypotheses about what happens during an outburst, Baade and Zwicky show that they probably release energy sufficient to maintain the supply of cosmic radiation as observed at the earth.

I should emphasise that in my own note I offered no theory of the origin of cosmic rays, but sought merely to answer the question: Can ordinary novæ outbursts in our own galaxy supply energy sufficient to give the observed intensity of cosmic radiation? I expected a negative answer. The method I followed in estimating the energy is due to Milne, and is independent of any hypothesis as to what happens actually during a nova outburst It turned out in point of fact that, on the present knowledge of stellar structure, one cannot definitely exclude the possibility of this source of the radiation, *on energy considerations alone*

The 'Lipotropic' Effect of Protein

EVIDENCE that proteins or substances closely associated with proteins exert a 'lipotropic'* effect has been reported previously from these departments[1,2] In the latter paper it was shown that when rats with fatty livers were placed on a choline-free diet consisting exclusively of sucrose, an increase of some 8 per cent of liver 'fat' was observed to take place within six days In a comparable experiment in which the ration contained 20 per cent protein as 'fat-free and vitamin-free casein' and 80 per cent sucrose, no increase in liver fat was observed at the end of six days It was also shown that 5 mgm of choline exerted a very definite effect on the liver fat of animals receiving a diet low in choline and containing 20 per cent fat. This effect may be regarded as much greater than that of the casein, and the results of more recent experiments indicate that as little as 1 mgm. of choline daily exerts at least as great a 'lipotropic' effect as 2 gm. of the alcohol and ether washed casein which we have used.

In several series of hitherto unpublished experiments in which large groups of animals were used, extensive deposition of liver fat has been obtained consistently with diets low in 'lipotropic' factors but containing 15–21 per cent protein and 3–40 per cent

* The term 'lipotropic' is used to describe substances which decrease the rate of deposition and accelerate the rate of removal of liver fat.

fat In a series of fifty animals in which a diet low in choline, but containing approximately 40 per cent fat and 21 per cent protein was provided, the average fat content at the end of three weeks was approximately 17 per cent This figure may be contrasted with that reported recently by Channon and Wilkinson[3]—12 5 per cent for one series of six animals which received 40 per cent fat and 5 per cent protein, and 8 9 per cent for another which received the fat and no protein. The 'lipotropic' effect of protein *per se* is not apparent from the comparison of these results from the two laboratories The simplest explanation is that the diet used by Channon and Wilkinson contained more non-protein 'lipotropic' factor than the one which we employed

The results in Table I show that in nine of the ten rats in a group receiving 15 per cent protein and only 20 per cent fat, excessive amounts of fat accumulated in the liver within fourteen days The deposition is as extensive as Channon and Wilkinson secured with double the amount of fat and one third the amount of protein in the diet The average gain in weight in the two groups of animals was of the same order

Table I Duration of Experiment, 14 Days

Rat No	Initial Wt	Final Wt	Cal per day	Total Fatty Acids of Liver	* Diet	
	gm	gm		per cent		per cent
1	166	172	60	18 6	Casein	11 5
2	146	154	51	9 1	Dried egg white	3 5
3	168	180	56	4 4	'Crisco'	20 0
4	140	144	41	11 6	Sucrose	58 3
5	146	136	46	18 5	Salt mixture	4 8
6	154	168	52	12 9	Agar	1 9
7	156	170	47	10 4	Vitamins A and D concentrate	
8	176	184	58	14 3		
9	156	164	56	15 7	Vitamin B_1 concentrate	
10	150	152	41	20 2	Choline content 1 25 mgm /100 gm	
Av	155 8	161 4	51	13 6		

* Average daily food consumption was 10 7 gm containing 0 134 mgm choline

In another section of their paper these authors state that the addition of 5 per cent protein prevents the deposition of fat which we noted when a diet composed exclusively of sucrose was used The figures to support this conclusion are not given, unless the authors refer to their diet (*G*) which contained approximately 5 per cent of 'Marmite' The protein and sucrose diet containing this material is stated to have provided 2 mgm of choline per rat daily. We would consider this a substantial amount of choline, and quite sufficient to exert an appreciable effect under the conditions of their experiments The possibility also exists that 'lipotropic' factors other than choline are present in the 'Marmite' preparation

We would like to suggest that Channon and Wilkinson have emphasised unduly the effect of slight or moderate undernutrition on the deposition of liver fat. They used a diet containing 40 per cent fat and 5 per cent protein, which resulted in an average content of 12·5 per cent liver fat at the end of three weeks. The average gain in weight of the six animals used was 4 gm It may be pointed out that equally satisfactory increases in weight with diets quite as effective in producing deposition of liver fat have been reported previously. For example, in an experiment in which the effect of betaine was being studied, two groups of animals—19 and 20 rats—showed an average increase in weight of 5 gm. and 7 gm at the end of three weeks[4]. Furthermore, Best, Channon and Ridout[5] reported two series of rats in which the average gain was 5 7 gm and 6·9 gm in twenty three days. In our experience, slight loss or gain in weight does not exert an appreciable effect on the deposition or disappearance of liver fat, or on the action of choline or other 'lipotropic' substances This conclusion is well supported by the results in Table II Twenty rats gained in weight, twelve lost weight slightly, while eight lost a considerable amount The livers were consistently fatty We do not believe, therefore, that Channon and Wilkinson were justified in disregarding the results of their experiment in which no protein was provided, and in which the average loss of weight was 19 gm. in three weeks. The average liver fat content was approximately 9 per cent There would appear to be little, if any, significant difference in the average liver fat obtained in this experiment and in those in which 5 or 10 per cent protein was provided The fact that the deposition of liver fat is not greater could be attributed, in our opinion, to 'lipotropic' factors contained in the 'Marmite'

Table II Duration of Experiment, 21 Days

No of Rats	Average Change in Weight	Total Fatty Acids of Liver	Diet
20*	gm + 5 4	per cent 19 2	per cent Casein 17 8 } Total protein, 21 1 per cent Dried egg white 3 3 } Sucrose 35·0 Beef fat 39 3 Salt mixture 4·6 Vitamin A and D concentrate Vitamin B_1 concentrate
12†	− 2 6	18 4	
8†	− 24 9	19 9	

* All rats gained weight
† All rats lost weight

The 'lipotropic' effect of protein should not be underestimated, but in our experience it could be accounted for if the protein contained two or three parts of choline, betaine, or other substances with similar action per 1,000 parts of protein. As we have emphasised previously, protein may exert its 'lipotropic' effect by providing betaine from the metabolism of amino acids, but it is obviously essential to use highly purified proteins or amino acids in investigating this possibility.

We regret that our more recent findings, which appear to us to change, in some degree, the interpretation of their results, were not available to Prof Channon and Mr Wilkinson before the publication of their paper. In the circumstances, however, we feel that confusion in the literature will be avoided by the report of these results.

Physiology of Whales

SIR LEONARD HILL[1] suggests that whales' blood should not become supersaturated with nitrogen since there is not enough air in the lungs. I have observed that Blue and Fin whales spend the vast majority of their lives submerged—at what depth we may never know—and that their sojourns at the surface are usually momentary. The result is that while the decompressed state of the whale lasts only for a few seconds in every ten to twenty minutes, the compressed state predominates. Therefore there is a constant passage of nitrogen into the blood and very little opportunity for it to return into the lungs. Supersaturation is bound to occur if the whale's dive is sufficiently deep.

May I be allowed to advance an *a posteriori* reason for believing that the whale dives deep enough to produce supersaturation of the blood with nitrogen? It lies in the phenomenon of nitrogen removal which occurs in whale blood and to which I have already directed attention[2]. The blood of Blue and Fin whales is capable of so absorbing atmospheric nitrogen that it is not to be regained by evacuation of the blood[3]. It is a most interesting fact that one of the few mammals which might run the risk of caisson sickness is just the one to have a mechanism for avoiding it.

Prof. Krogh has objected[4] that the rate of nitrogen removal shown in my experiments is too low to clear the blood of excess nitrogen quickly enough. The scope of my experiments sufficed only to establish the fact of nitrogen removal and not the rate, which may easily prove to be higher in the blood of living whales or when estimated by a more efficient technique than I was able to use.

In this connexion, I originally suggested that bacteria in the blood were the cause of the nitrogen removal. Further work on whale blood at the London School of Hygiene and Tropical Medicine has failed to support this. The nature of the reaction is not known, except that oxygen is apparently required.

With reference to Dr. Argyll Campbell's suggestion[5] that whales avoid caisson sickness by filling their lungs with water before a dive, I think it may safely be said that this is unlikely since the blast of exhalation is composed only of gases and water vapour. I have just returned from a whale-marking cruise, during which I frequently passed through the column of vapour left by a whale. On one occasion while I was standing in the bows of the whaler, a large Blue whale, about ninety feet long, came up directly beneath the bows and blew in my face. The blast was tremendous and seemed curiously cold, little warmer than the surrounding atmosphere, 5°–6° C. This chilliness is, I imagine, a result of the decompression of air in the whale's lungs. When the whale dives, the air is compressed and produces heat, which is absorbed gradually by the tissues of the lung. During the ascent to the surface the air expands and absorbs heat. The air in its chilly state is discharged before it has time to absorb heat from the lungs and, being saturated with water vapour, appears as a thin mist. This explains why the blast of whales is visible in the tropics where the breath of other mammals is invisible. But only the blasts from whales which have come up from a deep dive will be visible. No decompression cooling will occur in the lungs of whales which did not dive deep and come up again fairly rapidly.

Dr. J. S. Haldane tells me that the same phenomenon occurs in the air lock of caissons, where on decompression the air becomes very cold and supersaturated with moisture. Difficulty is experienced in getting the workers to stay long enough in the lock on account of the chilly discomfort.

Osmotic Pressure of Fixing Solutions

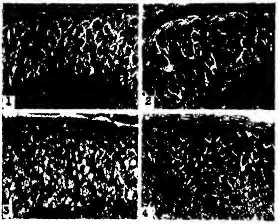
IT has long been the custom in many laboratories to make up certain fixatives in saline solutions, but the value of this practice has recently been questioned[1] on the ground that the osmotic pressure of most fixatives, as determined by the freezing point, is already greater than that of the tissues. However, since the particles of the fixative are presumably able to pass more or less freely across the surface membranes of the cells, it seems likely that they do not produce any effective osmotic pressure. If this is so, then the freezing point of a fixing solution is no guide to its 'physiological' osmotic pressure. Further, it is possible that the addition of salts to fixatives is necessary to prevent the distortion which would result from the fact that the particles of fixative differ from those of the tissue fluids in mobility and electrostatic charge.

Since very few critical data exist about the effects produced by fixatives made up in salt solutions[2], it was decided to test the question carefully, using a marine invertebrate in which osmotic effects should be especially conspicuous on account of the high internal concentration of salts. A number of fixatives, both single substances and fixing mixtures, were made up in distilled water and in sea-water, and were then tested as to their effects on the stellate ganglia of *Sepia officinalis*, in which the saline concentration of the blood is close to that of sea water. Each ganglion was cut into two pieces, one of which was fixed in the solution in sea-water, the other in that made up in distilled water. After fixation, the two pieces were transferred to a single receptacle and treated together in all subsequent processes, embedded side by side in paraffin and sectioned in the same block.

It was found that the presence of salts in the fixative is *essential* for good fixation, especially with fixatives which penetrate slowly[3] such as those composed of potassium bichromate, formaldehyde, chromic acid, picric acid or osmium tetroxide. For example, ganglia fixed in 1 per cent chromic acid or 4 per cent formaldehyde in distilled water showed very great distortion, due apparently to swelling and bursting of the cells (Figs. 1 and 2). Similarly, when such fixatives as Champy, Regaud or Flemming without acetic acid were made up in distilled water, they were found to cause bursting of the cells, especially at the centre of the piece, such effects being absent when the same solutions were made up in sea water (Figs. 3 and 4).

With solutions containing mercuric chloride or acetic acid, the difference between the results obtained with solutions made up in distilled and sea water was less marked, being least of all with Bouin's fluid and 'corrosive acetic', though even with those, some distortion could be detected when the fixative was made up in distilled water

These results confirm the theoretical anticipation that the particles of the fixative do not exert a fully effective osmotic pressure relative to the tissues One may conjecture that as soon as a piece of tissue is placed in a fixative made up in distilled water, ions begin to diffuse out from the intercellular fluids Therefore, until the more slowly moving particles of fixative arrive, the cells are effectively in a hypotonic medium, and hence swell and burst Fixing mixtures generally contain fast-moving ions the value of which is probably that they counteract this effect However, in many cases the same result can be better achieved simply by the addition of salts For example, 1 per cent chromic acid in sea water is a really excellent fixative for the nerve cells of *Sepia*



Nerve cells of *Sepia* in different fixing solutions. (1) 4 per cent formaldehyde in distilled water, (2) the same in sea water (3) Champy's solution in distilled water, (4) the same in sea water

When dealing with a marine animal, therefore, all fixatives should be made up in salt solutions similar to those found in the blood of the animal, especially if the fixative is based on formaldehyde, chromic acid, picric acid, potassium dichromate or osmium tetroxide. Further work is now being done to determine to what extent similar considerations apply to the fixation of the tissues of land animals

Chinese Influence on Western Alchemy

In his very able reconstruction of the origin and development of Western alchemy, Prof A. J Hopkins[1] does not discuss the possible influence of Chinese ideas as the seed which may have served to crystallise alchemical philosophy in Alexandria "somewhat after the beginning of the Christian era" He presents the origin of Egyptian alchemy as a perfectly logical and highly successful application of Platonic-Aristotelian philosophy to the apparently miraculous colour changes effected by the Egyptian craftsman in his closely allied arts of dyeing fabrics and colouring metals

Existing data[2] show that alchemical practices were common in China probably several centuries before they appeared in Egypt, and the suggestion has been made that the Western art possibly owes its inspiration to the former It thus becomes a matter of some interest to determine whether such a possibility is compatible with Prof Hopkins's thesis.

Chinese alchemy[2] was concerned primarily with the twin pursuits of immortality and transmutation In each case the goal was to be reached by changing the base, heavy, coarse, gross, material, undesirable, etc (that is, *Yin*), qualities of man or metal into the opposite noble, light, fine, ethereal, spiritual, desirable, etc (that is, *Yang*), attributes The underlying philosophy regarding why and how this could be accomplished was closely linked with Taoism and the search for the *Tao*, but one gains the impression that Taoism was much more inextricably intermingled with efforts towards longevity and immortality of man than with those towards the transmutation of metals Continuous life (that is, with no intervening death and bodily dissolution) involved bringing man into conformity with *Tao* through the conversion of his *Yin* (material, corruptible) nature into the *Yang* (spiritual, incorruptible, *Tao*) Some assumed knowledge of Taoism, therefore, would appear to have been pre-requisite for any hope of success, including at least a working hypothesis regarding the spiritual part of man On the other hand, in the case of the transmutation of metals as a means to mundane riches or position (that is, when not too closely associated with the idea of immortality and the life-prolonging 'elixir'), attention appears to have been centred more closely on the contraries, *Yin* and *Yang*

It is interesting to speculate on the reception in Alexandria which might have been accorded to marvellous tales of immortality and transmutation carried thither along the trade routes from China It seems probable that stories of immortality, of "the drug which prevents death", of the *hsien* or 'immortals' would have been listened to with incredulity. Since the *Tao* was not comprehended in China, in what a garbled and unintelligible form would Taoism have been discussed in Alexandria—if indeed its very abstruseness would not have prevented any such discussion. Furthermore, the Alexandrian had no personal evidence of immortality in the Chinese alchemical sense, and he already possessed several alternative hypotheses regarding the spirit and soul of man. But the fact that the early centuries of Western alchemy are free from the illusion of immortality, whereas this aspect was the earliest and always the most important feature in China, does not necessarily disprove a Chinese influence on the origin of alchemy in Egypt. Accounts of

transmutation, however, could have been received with enthusiasm. The two contraries (*Yin* and *Yang*) might have been identified with the opposing Greek 'elements' of *water* and *fire* and hence with the two 'qualities' of *mercury* and *sulphur* No understanding of *Taoism* would have been necessary The fact that transmutation was alleged to have been accomplished by changing lower qualities or natures into higher ones might have been sufficient to arouse interest, particularly in the mind of the Egyptian artisan who was daily confronted in his workshop with curious and striking changes in the appearance (notably colour) of metals under suitable treatment. Consequently, may not the alleged fact of the practical transmutation of the metals in China as related by traders in Alexandria have been the inspiration for that marriage of Greek philosophy and Egyptian craftsmanship which Prof Hopkins believes gave birth to Western alchemy?

The purpose of this note is to indicate that the apparent completeness of Prof Hopkins's picture does not automatically preclude the possibility that reports of Chinese alchemy may have had some influence on the origin of the Egyptian art Whether such an influence is considered to be 'improbable' or 'probable', present data still appear to indicate that it is 'possible'.

The Ratio 136/137 in Atomic Physics

IN an earlier letter[1] I suggested that some (or all) of the determinations of the specific electronic charge, e/m, disagreed with the value deduced from Sir Arthur Eddington's $M/m = 1847{\cdot}6$ theory (namely, $1{\cdot}7703 \times 10^7$ E.M.U.) because they were really measurements of

$$\frac{136}{137}(1{\cdot}770{,}3_1 \pm 0{\cdot}000{,}1_4) \times 10^7 = (1{\cdot}757{,}4 \pm 0{\cdot}000{,}14) \times 10^7 \text{ E.M.U.}$$

Prof. Birge[2] stated that the measurements agreed with my hypothesis even better than I had suggested, and Sir Arthur Eddington[3] suggested that, on theoretical grounds, the ratio would be expected to be very nearly 136/137.

The hypothesis can now be tested with precision. The seven most recent determinations[4] of e/m are:

$$\left\{\begin{array}{lll} 1{\cdot}757{,}9 & \pm 0{\cdot}002{,}5 & \times 10^7 \text{ E.M.U.} \\ 1{\cdot}758{,}7 & \pm 0{\cdot}000{,}9 & \\ 1{\cdot}757 & \pm 0{\cdot}001{,}5 & \\ 1{\cdot}758 & & \\ 1{\cdot}757 & \pm 0{\cdot}001 & \\ 1{\cdot}757{,}0 & \pm 0{\cdot}001{,}0 & \\ 1{\cdot}757{,}9 & \pm 0{\cdot}000{,}3 & \end{array}\right.$$

The unweighted mean of these seven,

$$(1{\cdot}757{,}6_4 \pm 0{\cdot}000{,}2) \times 10^7 \text{ E.M.U.},$$

may be compared with the value given by my hypothesis

$$(1{\cdot}757{,}4 \pm 0{\cdot}000{,}14) \times 10^7 \text{ E.M.U.}$$

Apparently the factor 136/137 is involved because we analyse a system, such as an atom, into 'separate parts' which 'interact' It seems that the effective mass of the less massive portion may have one of two distinct values according to our point of view.

Prof Birge[5] has pointed out that the estimate of the electronic charge deduced from Millikan's experiment ($4{\cdot}768 \times 10^{-10}$ E.S.U.) and the estimate obtained by the crystal-grating X-ray method ($4{\cdot}803 \times 10^{-10}$) are almost in the ratio 136/137 I wish to make a rather similar suggestion

I have formerly[6] given evidence that Sir Arthur Eddington's theoretical deductions $hc/2\pi e^2 = 137$ and $M/m = 1847{\cdot}6$ are true From these (with the help of Faraday's and Rydberg's constants) we can deduce[7] what I believe to be the most reliable estimate of e, namely

$$(4{\cdot}775{,}9 \pm 0{\cdot}000{,}4_3) \times 10^{-10} \text{ E.S.U.}$$

I would suggest that the crystal-grating X-ray estimate of e is really an estimate of

$$\frac{137}{136}(4{\cdot}775{,}9 \pm 0{\cdot}000{,}4_3) \times 10^{-10} = (4{\cdot}810{,}9 \pm 0{\cdot}000{,}4_3) \times 10^{-10} \text{ E.S.U.}$$

This value could also be obtained by assuming $hc/2\pi e^2 = 137$, but using $e/m = 1{\cdot}757_4$ in the Rydberg-Bohr equation

The most recent determinations of e by the X-ray method[8,9] give the values $4{\cdot}806 \pm 0{\cdot}003$ and $4{\cdot}805$, which are in reasonably good accord with the $4{\cdot}810_{,9}$ suggested above Ruark[10] finds that certain discrepancies disappear if he uses $e = 4{\cdot}806 \pm 0{\cdot}003$, $e/m = 1{\cdot}757{,}9 \pm 0{\cdot}0003$, $hc/2\pi e^2 = 137{\cdot}04$

If this second hypothesis of mine is correct, it would appear that the discrepancy between the two methods of estimating the electronic charge (or the two methods of estimating the X-ray wave-lengths) is due to the faulty analysis of a 'system' into two 'parts' I do not know where the error occurs. It may be due to our assuming that '*the* mass' contained in each unit cell in a crystal can be deduced by multiplying 'the volume' of the unit cell by the density of the crystal We naïvely contemplate the system as split up into parts.

Auger Effect and Forbidden Transitions

It is well known that after an atom has been ionised, for example in its K shell, the ensuing reorganisation of the extra-nuclear electronic structure is not by any means invariably accompanied by the emission of K-radiation. Quite frequently we have instead a 'radiationless' change of the type first completely specified by Rosseland, which results in the expulsion of a 'photo-electron of the second kind' and in leaving the atom doubly ionised—until further reorganisation occurs—in its X-ray levels. These photo-electrons of the second kind were observed by M. de Broglie, but the manner in which they originate was first clearly established by Auger's beautiful work with the Wilson cloud chamber, and it is convenient and not inappropriate to refer to them as Auger electrons.

In a recent very interesting paper[1], Mr. E. H. S. Burhop has calculated, by the methods of quantum mechanics, the relative probabilities of emission of different types of Auger electrons—that is, corresponding to different types of radiationless switches—from atoms initially ionised in the K shell. The Auger electrons resulting from interactions between the L shells fall into six sets, which may be classified thus:

(a) $L_{I}, L_{I} \rightarrow K, \infty$	(d) $L_{II}, L_{II} \rightarrow K, \infty$
(b) $L_{I}, L_{II}, \rightarrow K, \infty$	(e) $L_{II}, L_{III} \rightarrow K, \infty$
(c) $L_{I}, L_{III} \rightarrow K, \infty$	(f) $L_{III}, L_{III} \rightarrow K, \infty$,

the first two symbols indicating the electrons taking part in the disturbance, and the last two their immediate destinations—∞ being an obviously convenient symbol for 'outside the atom'.

Of the six sets, those in (a) will have the lowest energy, (b) and (c) will have approximately equal energies, appreciably greater than (a), and a similar thing is true of the fastest sets, (d), (e) and (f). An instrument of moderate resolving power would therefore (at least for light and moderately light atoms) record these six sets of Auger electrons as three groups, namely, I, set (a); II, sets (b) and (c); III, sets (d), (e) and (f). According to Burhop's calculations for element 47 (silver), the relative numbers of electrons in these three groups should be approximately in the proportion 1 : 3·4 : 6·7.

Electrons of Groups II and III were in fact recorded, with about the right relative intensities, by Robinson and Cassie[2] in a paper published in 1926 and quoted by Burhop. The less intense Group I was not observed in the 1926 experiments, but as its appearance—or non-appearance—is a matter of rather special interest, I wish now to point out that it was recorded in some later experiments of Robinson and Young[3], which have been overlooked by Mr. Burhop.

The special interest attached to this particular group lies in the fact that $L_{I} \rightarrow K$ is a forbidden transition in the X-ray spectral series scheme ($\Delta l = 0$, in the nlj notation for levels). Its appearance in our experiments and in the β-ray spectra of Ellis establishes experimentally a fundamental difference between the elementary processes which constitute the Auger effect, and the only alternative set of processes which could be invoked to explain the occurrence of photo-electrons of the second kind, namely, the production and internal absorption of the characteristic X-radiation of the atom.

In our experiments of 1930, the Auger electrons of Group I were not very clearly photographed. Since then, in the course of work on a different problem, and using an improved photographic technique, I have occasionally obtained very much better records of Auger electrons. One particularly good example may be quoted here, as it has not previously been published. The element under examination was copper (29); the velocities of the electrons are deduced from deflections in a magnetic field, and expressed[4] in terms of (rH) gauss cm. These are converted into equivalent frequencies (ν/R in Rydberg units) by the use of known constants, and hence by comparison with X-ray data the level of origin of the electron can be deduced with certainty.

Relative Intensity	rH	ν/R	Type of Electron
1	277·4$_{6}$	495·9	Group I
5	280·4$_{1}$	506·7	Group II
8	283·7$_{7}$	518·8	Group III

The agreement with the theory is striking. I think I should add that my own sense of satisfaction with the results is if anything enhanced by the feeling that it may be slightly unmerited; the approximations made in the quantum mechanical theory and—not less—the necessary latitude in my estimates of relative intensities, might well account for differences between experiment and theory appreciably greater than those recorded above. The general nature of the experimental results, however, leaves no room for reasonable doubt of the essential accuracy of the quantum mechanical methods which have been applied to the problem.

Supra-conducting Alloys

The behaviour of supra-conducting alloys has been found[1] to be different from that of pure metals in two ways:

(1) The magnetic induction (B) in alloys does not change to zero when they become supra-conducting.

(2) A supra-conducting alloy shows no discontinuity in the specific heat of such an order as would be expected according to Rutgers' formula[2].

These phenomena seem to be well established, as more recent experiments by de Haas and Casimir[3] and Tarr and Wilhelm[4] are in agreement with (1), while Shubnikow and Chotkewitsch[5] succeeded quite recently in confirming our result (2).

We measured the permeability of the same alloy the specific heat of which we determined and found that magnetic flux could penetrate it at much lower fields than the threshold values of supra-conductivity (compare ref. 3). That means that the condition $B = 0$ on which Gorter's[6] thermodynamical treatment is based is not entirely fulfilled in supra-conducting alloys and therefore Rutgers' formula must not be applied. In order to investigate the supra-conducting region where $B \neq 0$ (shaded, Fig. 1), we determined the change of induction which corresponds to a small change ΔH in the external field between T_1 and T_2 in rods of $Pb_{30\%}$ $Bi_{70\%}$. Curve 1 is the threshold curve from a very similar alloy[7], while curve 2 indicates the field strengths at which flux first penetrated the alloy.

(*a*) When the specimens were cooled previously in zero field, no change of induction was observed below curve 2 After passing curve 2, flux entered the alloy when switching on ΔH but no flux left when switching off. This continued until near curve 1 the changes became reversible and finally normal after passing curve 1

(*b*) On cooling to T_1 in H_1, no changes were observed below the reversible region near curve 1 for switching on or off ΔH

(*c*) Warming up again to T_2 gave the same result as in (*b*)

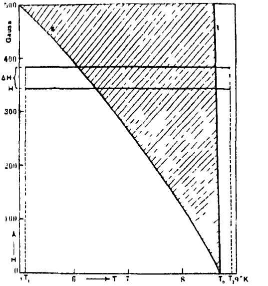

FIG 1

A possible explanation for all these phenomena is that the threshold value is high in some parts of the alloy while the main part has about the same value as pure metals Such a model would act like a fine supra conducting sponge the meshes of which are formed by annular regions of high threshold value impenetrable for magnetic flux that has once been caught in them. If the alloy is cooled in an external field, the sponge becomes supra-conducting first and the induction inside the meshes cannot change to zero (1). As the main part of the alloy has a low threshold value, this will cause only a very small discontinuity in the specific heat (2). Finally, this explanation conforms with the experiments (*a*) to (*c*). In (*a*), at first there is zero induction inside the meshes and no lines of force can enter the alloy After passing curve 2, some meshes of the sponge break down whenever the field is increased and magnetic flux enters them On switching off ΔH, however, this flux is not pressed out again as the material inside the meshes is no longer supra-conducting in this region of the H, T-diagram. This filling up with magnetic flux continues until near the threshold curve all changes of flux become reversible. In (*b*) and (*c*) the meshes already enclose lines of force in the normal state which are 'frozen' in as soon as the sponge becomes supra-conducting (1), and from now on no flux enters or leaves the sponge until finally curve 1 is reached again.

The question arises whether the skeleton of such a sponge of high threshold value is a supra-conductor of zero induction, or if the meshes are formed by supra-conducting regions the thickness of which is of the order of the penetration depth of currents in supra conductors[8] or even of atomic dimensions, for both of which the description of supra conductivity by zero induction has lost its significance Further, it is not yet clear if such a sponge has the same high threshold value throughout, or if it consists of meshes of all threshold values between curves 1 and 2, so that the supra conducting cross-section gradually increases with decreasing temperature Results similar to those in alloys have been obtained on fairly pure (90–99 per cent) tantalum For tantalum the steepness of curve 1 was found to be about 1,500 gauss/degree while that of curve 2 was 650 gauss/degree

A detailed account of these results will be published elsewhere

Electrical Resistance of Pure Aluminium at Liquid Helium Temperatures

THE electrical resistance of aluminium at liquid helium temperatures has been investigated by Tuyn and Kamerlingh Onnes[1], by Meissner and Voigt[2], and by Keesom[3], who discovered that this metal becomes supra-conducting at about 1 14° K The measurements of Meissner and Voigt appear to show that the resistance of aluminium in the liquid helium region between 4 2° and 1 3° K is not constant, but increases slightly with decreasing temperature On the other hand, Tuyn and Kamerlingh Onnes, as well as Keesom, have found that the resistance is constant in this region, but examination of their data shows that the residual resistance of their specimens was larger than those of Meissner and Voigt A slight increase of resistance at liquid helium temperatures has also been reported for molybdenum, cobalt and magnesium[3], and recently for gold[4] Since such a phenomenon is of considerable theoretical interest, and since we had at our disposal some samples of very pure aluminium, we have made further measurements on the resistance of this metal at liquid helium temperatures

The aluminium used in our investigation was supplied by the British Aluminium Co., and was specified to be at least 99·995 per cent pure It was drawn in this laboratory into wires of 0·15 mm diameter. Spectrographic analysis of the metal, taken before and after drawing, showed only minute impurities due to magnesium, calcium and perhaps copper Four specimens varying in length from 68 cm. to 86 cm. were selected from the wires, these are hereafter designated as Nos 3, 4, 5 and 6 Specimens 5 and 6 were annealed for 3 hours in high vacuum at 250° C., and No. 4 at 275° C ; specimen 3 was not annealed The values of $R_T/R_{0°C}$, calculated from the measured resistance of these wires at the temperatures indicated, are plotted in the accompanying graphs (Fig. 1, see over)

As seen from the graphs, the curves which best fit our values of $R_T/R_{0°C}$ are straight lines parallel to the temperature axis The absolute experimental error in the ratios we estimate as not greater than 0·00002 According to the data of Meissner and Voigt, we should expect an increase in $R_T/R_{0°C}$ of between 0 00007 and 0 00014 in the temperature interval 4 2° to 2 2° K Since Nos 5 and 6 show smaller values of $R_T/R_{0°C}$ in this region than any previously reported for aluminium, we conclude that, within the accuracy of our measurements, there is no increase in the resistance of pure aluminium down to 2 2° K

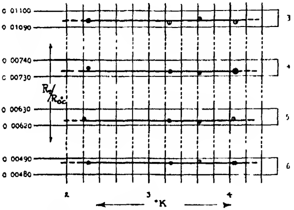

FIG 1 Relation of $R_T/R_{0°C}$ to temperature for aluminium at low temperature

The liquid helium for these experiments was produced by the new helium liquefier designed by Prof P Kapitza[5] A detailed report of these experiments will appear elsewhere

Range of Action of Surface Forces

IN a recent letter, Wilsdon, Bonnel and Nottage[1] suggest that anomalies observed in the vapour pressure, osmotic pressure and flow of water in porous materials and in capillaries are due to oriented chains of water molecules extending to a distance of 50 × 10⁻⁶ cm. from the surface. The possibility of such a structure has been suggested by Hardy[2], and by Watson and Menon[3], who found that a polished plate floated in air or water at a height of 40 × 10⁻⁶ cm from a parallel plate Further experiments[4], however, carried out at Sir William Hardy's suggestion showed that the separation of the plates was due to dust or to some similar commonplace cause.

More recently, Derjaguin[5], from observations on the resistance offered by water to the movement of an oscillating lens, concluded that a water film 1×10^{-5} cm. thick has a rigidity about 1/300 of that of solid lead. We have measured the resistance offered to the flow of thin liquid films enclosed between parallel surfaces. A relatively thick film (60×10^{-6} cm) of a 1 per cent solution of ammonium oleate in water (a liquid crystal known to possess a slight bulk rigidity) gave the results shown in Fig 1 (Curve 1), a pressure head of about 2 cm. being required to cause appreciable flow.

A water film, 16×10^{-6} cm. thick, gave Curve II, which is linear and passes through the origin Similar results were obtained with alcohol, cyclohexane,

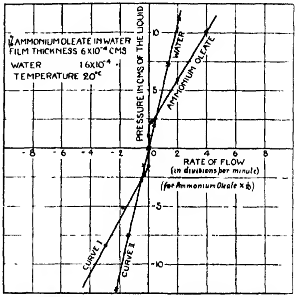

FIG 1 Resistance to flow of thin liquid films between parallel surfaces

acetic acid and ethyl palmitate Experiments with thinner films (*circa* 10^{-6} cm), and with liquids cooled to within 0·1° C. of the freezing point, also gave no evidence of rigidity, since the smallest measurable pressure (< 1 mm. head) always produced a normal flow and within the accuracy of the measurements *the viscosity of the film was the same as that of the liquid in bulk.*

The mechanical properties of the first few molecular layers of an adsorbed gas or liquid may be profoundly modified by the solid surface, but no such effects can be detected at distances of 10^{-6} cm and the extension of rigid chains to a distance of 50 × 10⁻⁶ cm. seems quite out of the question.

Interchange of Heavy Atoms in Organo-Metallic Methyls

USING the radioactive indicator method in which radioactive isotopes are used to indicate transference of atoms, we have obtained evidence which suggests that both lead and bismuth, deposited, presumably as oxides, on a metallic surface, can exchange with lead in lead tetra-methyl and bismuth in $Bi(CH_3)_3$ in ether solution at room temperature.

For bismuth the radioactive isotopes radium E and thorium C, periods 5 days and 60·5 minutes respectively, were used, and for lead, ThB with period 10·6 hours was employed.

The following experiment is typical. A piece of gold is activated with Th(B + C + C′ + C″) by exposure to thoron in the usual way. The gold is immersed in a solution of $Bi(CH_3)_3$ in ether for two hours. Then a small quantity of the solution is introduced into a small pot inside a Wilson expansion chamber filled with nitrogen. The solution evaporates from the pot, and eventually the $Bi(CH_3)_3$ settles on the boundaries of the chamber, perhaps oxidised by traces of oxygen. The characteristic α-tracks of Th(C′ + C″) are observed starting from parts of the chamber remote from the pot, thus proving that a volatile compound of ThC has been formed which has evaporated with the rest of the solution. The rate of decay of these α-tracks supports the view that the volatile radioactive substance contains ThC and not ThB. A similar effect is found if a source of RaE on nickel is inserted in $Bi(CH_3)_3$ solution. After a few days the shorter α particles of the subsequent element polonium are found distributed throughout the chamber.

It was necessary to test the hypothesis that the above effects are due to the liberation of 'free methyls' by the break up of heavy molecules under α and β ray bombardment. Such free methyls might pick up atoms from the metallic surface and thus form the volatile radioactive compounds observed. If this mechanism were correct, it must operate for any molecule rich in methyl groups and capable of being broken up. The experiments were therefore repeated, replacing the $Bi(CH_3)_3$ by $N(CH_3)_3$, $Si(CH_3)_4$ and $Sn(CH_3)_4$, but in each case the volatile α activity observed was too small to be distinguished definitely from the normal contamination and was certainly of a different order from the effect with $Bi(CH_3)_3$ and $Pb(CH_3)_4$. This indicates that the exchange process occurs mainly between atoms of the same atomic number and without the break up of the molecule.

With $Pb(CH_3)_4$ and Th(B + C + C′ + C″) the effect is remarkable in that the unmistakable α emission of Th(C + C′) is observed immediately evaporation begins, and photographs showing these α-particles starting in the gas have been obtained. This indicates the unexpected presence of a volatile bismuth compound. On the other hand, the rate of decay of the activity in the chamber is consistent with the ten-hour period of ThB, which must therefore have distilled over with the ThC. This may be explained if the oxidation of $Bi(CH_3)_3$ is inhibited or retarded in the $Pb(CH_3)_4$ solution, which will therefore contain equilibrium amounts of $ThC(CH_3)_3$ and $ThB(CH_3)_4$ which will evaporate together.

Measurements of the rate of interchange are in progress using an ionisation method and also a tube counter system constructed by Miss E. E. Widdowson, whom we wish to thank, together with Prof. Arthur Ellis, who kindly gave us some old radon tubes.

Ebulliometric Determination of the Degree of Decomposition of an Organic Substance

In previous papers it has been shown that the application of an ebulliometer with several dephlegmators[1] (Fig. 1) filled with an azeotropic mixture of benzene and ethanol or any other binary mixture forming with water a ternary azeotrope, enables one to determine with an accuracy up to 0·001 per cent the quantity of moisture in solid organic substances soluble in the above-mentioned azeotrope. The same method can be applied for determinations of the degree of decomposition of organic substances forming water as one of the products of decomposition.

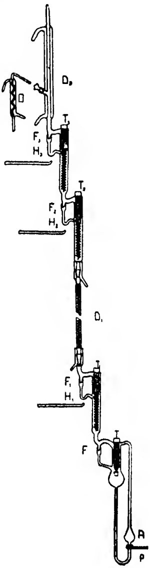

FIG. 1

Let us suppose that the decomposition of succinic acid by heating to the temperature t is examined. For this purpose a certain quantity of this acid is placed in a test-tube which is afterwards closed like a Carius tube. After heating for a certain time at the given temperature, the tube is carefully shaken and the substance is brought to the vessel A of the ebulliometer, which is filled with azeotropic mixture of benzene and ethanol. The water formed by the decomposition of succinic acid forms a ternary system (azeotropic mixture) with benzene and ethanol, which has a lower boiling point than the mixture of benzene and ethanol. Noting the lowering of the condensation temperature in the upper part of the ebulliometer (the thermometer is placed in the uppermost test-tube of the apparatus), it is possible to calculate the quantity of water formed, after carrying out a direct determination of the lowering of temperature per milligram of water, introduced into the ebulliometer. The heating of the reflux tubes by microburners must be so regulated that the number of drops flowing through the drop-counters F, F_1, F_2, F_3 is approximately the same in both experiments.

The method makes it possible to determine the formation of 0·001 per cent of water by the decomposition of substances. Details will be published elsewhere.

Ebulliometric Method of Determining the Amount of a Substance Adsorbed on the Surface of Solid Substances

EBULLIOMETRIC apparatus with a few dephlegmators constructed by W Swietoslawski, applied to the determination of very small quantities of impurities[1], can be used to investigate the amount of substances adsorbed on the surfaces of solid materials such as glass or metals

The ebulliometer is filled with a substance which gives an azeotropic mixture with that adsorbed At the beginning of the measurement, the liquid in the apparatus is allowed to boil, the distribution of temperatures is noted, and afterwards it is cooled down The adsorbing system is placed in the tube with vapour of the substance to be adsorbed, then cleaned with a stream of dry air, and introduced into the column of the apparatus After heating up again the liquid in the ebulliometer, its vapour flows to the column and removes the adsorbed substance from the surface of the adsorbent, and forms the azeotropic mixture which rises to the upper section of the apparatus There a considerable lowering of the temperature of condensation of vapours is observed Then a known amount of the same substance that was adsorbed is introduced into the apparatus, in order to find the lowering of the temperature of condensation produced by 1 mgm of the substance under investigation From the lowering caused by 1 mgm and that produced by the substance adsorbed it is possible to calculate the amount of the substance adsorbed on 1 sq cm of the surface of the investigated materials

Investigations were carried out with benzene vapour adsorbed on the surface of glass and copper at 18° C In the ebulliometer there was an azeotropic mixture of ethanol and water The numerical data obtained for these systems are as follows

Amount of benzene adsorbed on 1 cm ^{2} at 18° C

Amount of benzene adsorbed on 1 cm ^{2}

	Glass		Copper

Compressibility of Electrolytic Solutions

THE adiabatic compressibilities of some strong electrolytes have been measured as a function of the molar concentration c by means of a new optical method, which has been developed in the Department of Electrolytic Research of the University of Cologne. It was found that the linear dependence of the apparent molal compressibility on the square root of the concentration is valid (within the experimental error of 0·1 per thousand), also in dilute solutions, even in solutions ten times more dilute than those on which Gucker[1] based his calculations

The limiting slopes derived from the interionic attraction theory by Gucker agree with our new experimental results only for the 1-1- and 1-2-valent salts, whereas in the case of electrolytes of higher valency a smaller slope was measured than that expected by theory Different electrolytes of the same valency type show individual characteristics, a fact which Gucker was the first to point out[2]

The compressibility, k, as a function of c is given by the following relation. $k = Ac + Bc^{3/2}$ Gucker supposed that the apparent molal compressibility of non-electrolytes is also governed by the square root law with respect to c This was not confirmed by our new measurements on cane sugar We intend to make a further improvement in the experimental method by determining the middle of the nodal lines by a photometric method It will then be possible to reach the region which is of special interest for the interionic attraction theory. Many other problems will be of great interest for example, the effect of dielectric constant or temperature upon the compressibility

A detailed account of the work will be published soon by one of us

Mathematical Psychology of War

AS NATURE has encouraged scientific workers to think about public affairs, I beg space to remark that equations, describing the onset of the War, and published under the above title* in 1919, have again a topical interest, in connexion with the present regrettable rearmament In revised form

$$\frac{dx_1}{dt} = k_{12}\, x_2 - \gamma_1 x_1 + \Delta_1 ;$$

$$\frac{dx_2}{dt} = k_{21} . x_1 - \gamma_2 x_2 + \Delta_2$$

The suffixes 1 and 2 refer to the opposing nations, or groups of nations The symbol x denotes the variable preparedness for war, t is the time, k is a 'defence-coefficient' and is positive and more or less constant; γ is a 'fatigue and expense' coefficient and is also positive and moderately constant Lastly, Δ represents those dissatisfactions-with-treaties, which tend to provoke a breach of the peace.

If Δ_1, Δ_2, x_1, x_2 could all have been made zero simultaneously, the equations show that x_1 and x_2 would have remained zero That ideal condition would have been permanent peace by disarmament-and-satisfaction The equations further imply that mutual disarmament without satisfaction is not permanent, for if x_1 and x_2 instantaneously vanish, $dx_1/dt = \Delta_1$ and $dx_2/dt = \Delta_2$

Unilateral disarmament corresponds to putting $x_2 = 0$ at a certain instant We have at that time:

$$\frac{dx_1}{dt} = - \gamma_1 x_1 + \Delta_1 ,$$

$$\frac{dx_2}{dt} = k_{21}\, x_1 + \Delta_2 .$$

* Obtainable from Geneva Research Center, 2 Place Chateaubriand, Geneva, price 5s post paid. Few copies remain

The second of these equations implies that x_2 will not remain zero; later, when x_2 has grown, the term $k_{12}.x_2$ will cause x_1 to grow also. So unilateral disarmament is not permanent, as Germany has shown us.

A race in armaments, such as was in progress in 1912, occurs when the defence-terms predominate in the second members of the equations. We have then approximately

$$\frac{dx_1}{dt} = k_{12}\,x_2, \qquad \frac{dx_2}{dt} = k_{21}\,x_1,$$

and both x_1 and x_2 tend towards infinity.

I submit that the equations do describe, at least crudely, the way in which things have been done in the past. As to the future, while indicating the desirability of disarmament-and-satisfaction, they suggest that such a condition might easily become unstable, and that there is a need for controlling terms of a quite novel type. More strength to the statesmen who are trying to provide such!

Some Uses of the Air-Driven Spinning Top

SINCE no measurements have so far been published, from any country, on colloidal systems using the air-driven spinning top of Henriot and Huguenard[1], it is evident that the great importance of this remarkable tool has escaped the attention of most laboratories. This is especially surprising in view of the fact that any good mechanic can make the necessary simple equipment (a stator and a hollow rotor) for a cost of about two or three pounds, and that for most purposes no special precautions need be taken as to constancy of temperature or control of pressure. With much less than the pressure of air available in an ordinary garage, the top may spin at several thousand revolutions per second, producing centrifugal forces of the order of 10^{5}–10^{6} times gravity.

We therefore mention a few of the purposes which since 1931 we have found to be served by the use of this intriguing invention in one of the forms perfected by the originators[1]. This is quite apart from the elaborate studies which have proved necessary in the attempt to develop the top as a convectionless transparent ultra-centrifuge, paralleling those of Svedberg. These will be reported on elsewhere[2]. We only remark here that in one case last year an accidental disturbance created a sharp boundary in a sedimenting solution of mercuric chloride, affording a unique opportunity of observing a sedimentation constant S, as measured upon the photographs, equal to $8{\cdot}90 \times 10^{-13}$ as compared with theory $8{\cdot}91 \times 10^{-13}$.

Convection does not occur in an immobilised system. Sedimentation may be observed by eye, by callipers, by a scraping pipette, or by pouring off supernatant liquid and weighing. Evaporation is minimised by a solid cover or by a thin piece of cellophane which can be perforated by a hot wire without disturbing the spinning top. We find that the best method of preventing interaction between steel tops and their contents is to bake on several thin coats of bakelite lacquer. One may take advantage of these factors in the following ways:

(a) Measurement of rate of sedimentation of jellies and curds. Examples studied: agar, silicic acid, and sodium palmitate in water; soap jellies in non-aqueous solvents.

(b) Purification of gelating colloids. Examples studied: agar, where half of the agar does not sediment with the rest of the agar jelly.

(c) Measurement of swelling pressure of jellies. When the jelly refuses to sediment further, it is in equilibrium with its swelling pressure.

(d) Replacement of ultra filtration. Supernatant liquid or mother liquor may be removed from a sedimenting system, avoiding all effects of pore-size or adsorption.

(e) Measurement of bound or combined water in colloidal or biological systems using a reference substance separated as in (d) for analysis.

(f) Bound water, by increasing the density through addition of indifferent substances until sedimentation just ceases to occur. Then the reciprocal of the density of the system is identical with the partial specific volume of the non-sedimenting structure. The composition corresponding to this partial specific volume may be read from a table or graph of densities against composition. The simplest graph to read is that for the jelly itself, as for example agar in pure water.

(g) Determination of sorption. Example: methylene blue, which is strongly adsorbed by most materials, using method (d).

(h) There are many other possibilities, such as the observation of sedimentation equilibrium within any immobilised system.

We are of the opinion that all chemical, biological, metallographic and applied science laboratories might well employ one or more of these simple devices. Physical laboratories have long recognised the usefulness of solid tops as originally developed[1] for the measurement of the velocity of light, either with a path of only one metre or with the refinements and precision of the last work of Michelson.

A New Test of the Magneto-Ionic Theory

ACCORDING to the magneto-ionic theory of Appleton[1], we should expect a wireless wave incident on the ionosphere to be returned to the earth as two differently polarised components (the ordinary and the extraordinary) with a slight difference in the time of travel. For wave-lengths shorter than 214 metres (the critical wave-length of the theory, given by the expression $\lambda = \frac{2\pi mc^2}{He}$), the theory has been experimentally confirmed[2,3] and the following points are well established:

(a) The two magneto-ionic components are circularly polarised.

(b) The left-handed (ordinary) component penetrates the F region and the E region more easily than the right-handed (extraordinary).

(c) The intensity of the extraordinary wave decreases markedly as the magneto-ionic critical wave-length is approached. The theory predicts different results for waves of length greater than 214 metres, but so far as we know, experiments have not been made to test it for these wave-lengths.

To test the theory for the longer wave-lengths the following conditions are necessary :

(a) The wave-length must be sufficiently removed from the magneto-ionic critical wave-length, so that the extraordinary wave is not too strongly absorbed This necessitates the use of a wave-length greater than 400 m

(b) To investigate the relative penetrating powers of the two magneto-ionic components, it is necessary to work at a time when the ionisation density in one of the ionospheric regions is small enough to permit at least one component to penetrate This occurs only with the E region, and then only at midnight in midwinter.

During January and February of this year we have made experiments to compare the behaviour of waves of length greater than 214 m with the well-known behaviour on shorter wave-lengths Pulse transmissions of the Breit and Tuve type were provided from a nearby transmitter and the wave-length could be varied within the range from 400 metres to 500 metres The receiver was equipped with a circularly polarised aerial so that the polarisation of the received echoes could be investigated The values of the equivalent height, the state of polarisation, and the relative intensity of the two component waves were all determined for a series of different wave lengths

The results of the experiments were as follows :

(a) For wave lengths greater than 214 metres the right-handed (extraordinary) component penetrates the E region more easily than the left handed, so that it may be reflected from the F region while the left-handed component is reflected from the E region. This is the opposite of what happens on the shorter waves and is in accordance with the theory

(b) The fact that the extraordinary component is reflected at all means that in the reflecting regions the quasi-transverse approximation to the magneto-ionic equations must hold, that is,

$$\frac{y_T^4}{4y_L^2} > z^2 + (1 - x)^2,$$

using the nomenclature of reference 1.

(c) For wave-lengths which just penetrate the E region, the F region echo is split, with the extraordinary component uppermost This may be due to differences in the group velocities of the two components in the E region or in an intermediate region.

(d) On several occasions there was evidence of reflection from an intermediate region at an equivalent height of about 150 km

Detonation of Nitrogen Iodide, $NI_3.NH_3$

WHEN moist nitrogen iodide is suspended in air over phosphorus pentoxide in a glass vessel and the vessel evacuated by a mercury vapour pump, the crystals detonate as soon as they become dry On the other hand, the substance can be completely decomposed into iodine and permanent gases without detonation occurring if the pressure of the permanent gases be not allowed to fall below 2×10^{-2} cm. At room temperature the decomposition can be completed in 12–24 hours On carrying out the decomposition at $-20°$ C. there is little reaction until the water is removed, after which the pressure rises linearly for a time. As iodine begins to condense out on the walls of the glass vessel, the rate of evolution of gas decreases and ultimately the pressure reaches a constant value, although some nitrogen iodide is still undecomposed After this steady state is reached, on subjecting the residue to a hard vacuum it detonates On detonation, the amount of permanent gas produced is only 30–50 per cent of that liberated during the thermal decomposition

The thermal reaction is retarded by the easily condensible products of decomposition and also by water, and on removal of these substances, nitrogen iodide detonates spontaneously This accounts for its extreme sensitivity to a blow, for this will create fresh surfaces which are unstable. The solid reaction gives rise to reaction chains which are infinite in length when the surface is free from adsorbed gases

A Further Reappearance of the Second Red-Eye Mutation in *Gammarus*

THROUGH the kindness of Mrs Sexton, of the Marine Biological Laboratory, Plymouth, I was able to obtain a stock of a new mutation producing red, instead of the normal black, facets in the eyes of the amphipod *Gammarus chevreuxi*, Sexton. It had appeared in the first F_2 of a pair from a dredging taken in Chelson Meadows, near Plymouth, about a year ago, and my intention was to make a study of the effects of temperature on this mutant similar to that made by E B Ford and J S Huxley (1927) on the first red eye mutation For this purpose it was necessary to cross the new form with the red-eye mutations which had previously appeared, in order to determine whether or not it was homologous with any of them

The following results have now been obtained When crossed with the first red-eye stock (r_1), all the F_1 offspring had black eyes With the second red-eye stock (r_2), the following F_1 families have appeared (a) One black- and sixteen red-eyed young (b) With different parents . a single red-eyed specimen, about six weeks after mating (c) With different parents again . three red-eyed young about a fortnight after mating, and a further seven red-eyed ones about three weeks later

Doubtless the explanation of the single black-eyed individual in the first family obtained with the second red-eye stock, is that some of the sperms from the previous mate of the female had remained behind and fertilised one or more of the eggs, causing the appearance of a heterozygous black-eyed specimen—not an unusual phenomenon in *Gammarus*. The long period elapsing between the separation of the female and the appearance of the young precludes such an occurrence in the second brood, while in the last instance, the female, after producing the first red-eyed family, had been mated with a homozygous black-eyed male before being again given a red-eyed mate, so that if any sperm had been left over from a previous mating some of the second family would have had black eyes ('black' is dominant to 'red'). The present gene therefore proves to be a reappearance of the second red-eye factor.

From the results already obtained by Sexton and Clark[1] we may infer that this recessive gene is somewhat widely spread in the wild population, and any further information on this subject appears to be of value.

Composition of Interveinal Mosaic of Potatoes

In a recent paper from Madison, Wis, Koch and Johnson[1] state that they have found in interveinal mosaic of potato received from this laboratory a "streak" (Table VII) which is presumably identical with the new virus described in the text (p 45) as "potato streak virus". We had already found in 1933 and 1934 that this interveinal mosaic results from the combined action of viruses of two different types, one of which may correspond to the streak of Koch and Johnson, since there is no present evidence of a further constituent In the circumstances, it is desirable to publish this note although the work is not complete

One of the constituents of interveinal mosaic is a virus of the *X*-type which has no known insect vector The other constituent is selectively transmitted under certain conditions by the aphis *Myzus persicæ*, Sulz, contrary to the conclusion of Koch and Johnson regarding their virus, and it has been isolated both in this way and by passage of interveinal mosaic through the potato variety Arran Crest, in which the *X*-virus does not survive

The virus thus separated by the two methods sometimes produces on the foliage of President potato a slight transient mottle, but one of its diagnostic features is the production of irregularly arranged necrotic blotches in the cortex and pith of the tubers of this variety, and it is regarded as responsible for this symptom in interveinal mosaic Koch and Johnson make no reference to this, and they were consequently not in a position to know that the virus is related to, if not identical with, that causing phloem parenchyma necrosis (or pseudo-net necrosis) as defined by Quanjer, Thung and Elze[2,3] Its full identity, however, has not yet been satisfactorily established, and it is provisionally entitled the 'tuber blotch virus'.

Another diagnostic character of the virus is its power of combining with simple mosaic (virus *X*), thereby intensifying it to interveinal mosaic, and the latter has been synthesised in this way. This reaction can only follow in a variety which is tolerant of both viruses, for if it is intolerant of either, 'streak' results Thus the simple mosaic element alone would cause this symptpm in Arran Crest, while the tuber blotch virus was presumably responsible for the 'streak' which Koch and Johnson produced in the experimental Bliss Triumph, since the plants already carried the equivalent of simple mosaic.

The tuber blotch virus is readily inoculable into tobacco (var. White Burley) and *Datura Stramonium*, but it is carried by the latter and also probably by the former. It does not survive nine days *in vitro* at room temperature, and does not pass the L3 or L5 Pasteur-Chamberland filters, while the *X* virus does so, and has been readily separated in this way.

Whatever the identity of the tuber blotch virus turns out to be, it is unfortunate in the present circumstances that Koch and Johnson should have given the virus they worked with the new name of "potato streak virus" This term is likely to lead to further confusion, since it had been used previously in a looser sense, and at the present time the name 'streak' as applied to potato viruses is devoid of meaning, seeing that the majority, if not all, of them produce streaking on intolerant varieties

Physiological Polarity in *Aspergillus*

Working with a certain strain of *Aspergillus nidulans* (Eidam), Winter, I have proved and described a particular type of 'physiological polarity'[1]. It is important to verify this polarity with other strains of the same species

I should be obliged therefore if mycologists would send me specimens of *Aspergillus nidulans* with perithecia, and indication of the origin I require the fungus from its natural sources, and not from strains found in the laboratory, as it is necessary that I should carry out the isolation myself I should be grateful to have the material sent c/o Centraalbureau voor Schimmelcultures, Baarn, Holland, where I am working at present

Preparation of Diazomethane and its Homologues in the Free State

We have recently prepared for the first time an extended series of the homologues of diazomethane, but only in ethereal solution[1]

For the systematic study which we contemplate of the physical and also of the chemical properties of this series, however, it is requisite that the several compounds should be available in the free condition. We have now achieved this in a number of instances by decomposing the nitroso-β-alkylaminoi*so*butyl methyl ketones in a reflux apparatus at 70° under somewhat reduced pressure in presence of a small quantity of anisole, by means of sodium benzylate, and obtained yields which in certain cases even surpass those already recorded; for example, of diazomethane 81 per cent, of diazoethane 64 per cent, of diazopropane 59 per cent, of diazobutane 46 per cent.

Points from Foregoing Letters

Sir Joseph Larmor makes critical comments on theories of magneto-optic rotation and suggests that valuable information might be obtained by the application of modern technique to the measurement of the intensity across the Zeeman spectral components (spectrum lines resolved and polarised by the action of a magnetic field)

Artificially produced radioelements can be partially separated by carrying out the transmutation in the presence of an electric field, according to Prof F A Paneth and Mr J W J Fay Using a gaseous arsenic compound which by bombardment with neutrons gave radioactive arsenic, they were able, by the application of an alternating electric field, to concentrate 20,000-fold the radioactive material produced

Accepting the view that primary cosmic rays consist of two groups of particles, namely, positive and negative electrons and positively charged hydrogen nuclei, Dr Pierre Auger indicates that, as they penetrate through matter, their interaction with elements of low and high atomic weight leads to the production of secondary phenomena, such as the penetrating radiation and electron showers observed

The power of proteins and similar substances (choline, betaine) of decreasing the fat content of liver is discussed by Prof C H Best and Messrs M E Huntsman and J H Ridout They give results of experiments on rats which lead them to believe that Channon and Wilkinson have emphasised unduly the effect of moderate under-nutrition on the deposition of liver fat; they find that slight change in body weight does not affect the liver fat balance

Mr Alec H Laurie, who has just returned from a whaling expedition, describes personal observations indicating that whales do not fill their lungs with water when diving (to prevent caisson sickness due to liberation of dissolved nitrogen) Mr Laurie's previous experiments with whale blood have shown that it has the property of using up dissolved nitrogen

The freezing point of a solution is no guide to the osmotic pressure it will exert across an animal membrane Mr J Z Young therefore advises that solutions used for hardening or 'fixing' tissues of sea animals should contain the saline constituents of sea-water in the same concentration, in order to prevent distortion or bursting of the cells due to penetration of water.

Dr W N Bond offers further evidence in support of his suggestion that the cause of the discrepancy between experiment and Eddington's theoretical value, M/m, for the electron, is that experiment measures not e/m but 136/137 e/m It is suggested further that since X-ray determinations and Millikan's method give different values for the electronic charge, approximately in the value 137/136, the reason for this lack of agreement is the same as in the first case, namely, faulty analysis of a 'system' into 'parts'

Mr. K Mendelssohn and Miss Judith R Moore describe the magnetic properties of a lead-bismuth alloy at temperatures near the absolute zero, when it becomes supra-conducting A possible explanation for the phenomena observed is that the 'threshold value' (temperature at which supra-conductivity begins) is high in some parts of the alloy while the main part has about the same value as pure metals Such a model would act like a fine supra-conducting sponge, the meshes of which are formed by annular regions of high threshold value impenetrable for magnetic flux that has once been caught in them

The electrical resistance of very pure aluminium just before it becomes supra-conducting has been investigated by Mr H A Boorse and Dr H Niewodniczański, between 4 2° and 2 2° K, the resistance is constant

Dr F P Bowden and Mr S H Bastow have measured the resistance to flow of thin films of water and of soap (ammonium oleate) solution, and have failed to confirm the rigidity deduced by Derjaguin from observations on the resistance offered by water to the movement of an oscillating lens This, they believe, disproves the view that oriented chains of water molecules may extend to a distance of 5 μ from the surface

Using radioactive isotopes as indicators, Mrs Alice Leigh-Smith and Dr H O W Richardson find that in compounds of metals with organic radicles, exchange of atoms of the same atomic number occurs without the break-up of the molecules

A method of determining minor quantities of water, such as are produced during the partial decomposition of some organic compounds, is described by Prof W Swietoslawski. It depends upon the lowering of the boiling point of azeotropic mixtures of certain organic liquids (mixtures which distil in a constant ratio) produced by small amounts of moisture The method has been applied by Mr M Wojciechowski to the determination of small amounts of substances adsorbed at solid surfaces

By means of a new optical method, Prof. H Falkenhagen and Mr Ch Bachem have measured the compressibility of solutions They find a linear relation between the apparent molal compressibility and the square root of the concentration of the electrolyte, in accordance with Gucker's theory, but the relation does not hold for non-electrolytes, such as sugar

Dr L F Richardson directs attention to a mathematical formula in which he has attempted to express the armament race between opposing nations or groups of nations in terms of a "defence coefficient", a "fatigue and expense coefficient" and a quantity depending upon dissatisfaction with treaties

Messrs F T Farmer and J A Ratcliffe have investigated the application of Appleton's theory of the ionosphere to radiation of wave length greater than the critical value of 214 m. Observation of the ordinary and extraordinary reflected rays which have partially penetrated the E and F reflecting layers confirms the theory, and suggests that reflection occasionally occurs from an intermediate region at 150 km

Mr J. B. Loughnane and Miss Phyllis Clinch state that interveinal mosaic disease of potatoes is due to the combined action of two viruses, one of which is transmitted by the green fly *Myzus persicæ*, whilst the other has no insect carrier.

Mr. D. W. Adamson and Prof J. Kenner report the preparation, for the first time, of a number of compounds belonging to the diazomethane ($C_1H_2N_2$) series These are highly reactive, poisonous and explosive substances.

News and Views

Award of the Mueller Medal to Dr. R. J. Tillyard, F.R.S.

THE Mueller Medal of the Australian and New Zealand Association for the Advancement of Science was presented to Dr R J Tillyard, Chief Commonwealth Entomologist, at the recent annual meeting of the Royal Society of Australia held at Canberra. This medal, which was established in 1896 by a group of scientific workers in Victoria, commemorates the services to Australia of Baron Ferdinand von Mueller, and is the premier award in the gift of Australian men of science According to the *Canberra Times*, Dr. A. B Walkom, general secretary of the Australian and New Zealand Association, made the presentation. In his address, he recalled the names of previous recipients of the Mueller Medal, among whom have been J. H Maiden, Leonard Cockayne, W. Howchin, Sir Douglas Mawson, Sir Edgeworth David and Prof. Wood Jones Dr. Tillyard, he said, has many notable investigations to his credit, in particular, he has studied the biology of the dragonflies, the wing venation of insects and the determination and classification of fossil insects He has also published a valuable and comprehensive textbook on the insects of Australia and New Zealand Dr Tillyard's work in entomology, in both New Zealand and Australia, has been of outstanding value, establishing principles and facts of wide interest and great importance

Presentation to Sir Denison Ross

AT the recent annual anniversary general meeting of the Royal Asiatic Society, Sir Denison Ross, director of the School of Oriental Studies, London, was presented with the Triennial Gold Medal for his work in forwarding Oriental research during the period concerned The presentation was made by H.E. The Iranian Minister, a very happy arrangement as a great deal of Sir Denison Ross's time has been devoted to the study of the Persian language and Iranian dialects He was the guest of the Iranian Government on the occasion of the festivities held in Iran, in honour of the millenary of Firdausi, the national poet of Persia. The gold medal trust was founded in 1897 to commemorate the Diamond Jubilee of Queen Victoria. The selection of the recipient is made by a special committee appointed by the president and council of the Royal Asiatic Society for the purpose, from among their number The previous recipients have included Prof. E. B. Cowell, E W. West, Sir William Pope, V A. Smith, A. H. Sayce, D. S. Margoliouth and Sir Aurel Stein. In mentioning some of Sir Denison's services, the Iranian Minister dwelt on his love of Persian studies and his constant travel in the East He thought that Sir Denison must own a special kind of magic carpet from the "Arabian Nights", for he attended the Firdausi celebrations in Teheran and elsewhere, but was able to reach London in time for Firdausi week here. His studies had kept alight the torch of Oriental learning in England and India.

U.S. National Academy: Elections and Awards

IT is announced by Science Service, Washington, D.C, that the following have been elected members of the U S National Academy of Sciences Dr N. L. Bowen, Carnegie Institution of Washington, geologist; Dr. C M. Child, the University of Chicago, zoologist; Dr. G E Coghill, Wistar Institute, Philadelphia, chemist; Dr James Ewing, Memorial Hospital, New York City, pathologist; Dr. M. L Fernald, Gray Herbarium, Cambridge, Mass, botanist, Dr Harvey Fletcher, Bell Telephone Laboratories, New York City, physicist, Dr Ross Aiken Gortner, University of Minnesota, chemist, Dr. E A. Hooton, Harvard University, anthropologist, Dr. J C Hunsaker, Massachusetts Institute of Technology, aerodynamist, Dr. Walter S. Hunter, Clark University, psychologist; Dr Dunham Jackson, University of Minnesota, mathematician, Dr Chester R Longwell, Yale University, geologist, Dr H C Urey, Columbia University, chemist, Dr. J. H. Van Vleck, Harvard University, physicist. New foreign associates of the Academy are Dr J. S Haldane, director of the Mining Research Laboratory and honorary professor in the University of Birmingham, and Dr Jules Bordet, director of the Pasteur Institute, Brussels Dr Frank R Lillie has been elected president of the National Academy of Sciences for a term of four years He is dean of the division of biological sciences at the University of Chicago and president of the Woods Hole, Mass., Marine Biological Laboratory

THE following awards have been made by the National Academy of Sciences *Public Welfare Medal* to Prof. August Vollmer, of the University of California, for his work in police administration; *Daniel Giraud Elliot Medal* to Dr James P. Chaplin, of the American Museum of Natural History, for his work on the birds of the Belgian Congo, *Henry Draper Medal* for astronomy to Dr J S. Plaskett, director of the Astrophysical Laboratory at Victoria, British Columbia; and *Agassiz Medal* for oceanography to Prof. Haakon Hasberg Gran, of Oslo

"Backward Tracts" in the India Bill

FURTHER consideration was given to the position of the aboriginal tribes under the provisions of the India Bill in Committee of the House of Commons on May 9 and 13, when an amendment to Clause 6 was moved by Mr. Cadogan (Finchley, U) proposing the extension and modification of the excluded and partially excluded areas named in the schedule thereto. The "anthropologists", as Mr. Winston Churchill happily termed the supporters of the amendment, urged with vigour the necessity for a much wider application of the principle of exclusion, by which jungle and hill peoples living under tribal conditions remain outside the jurisdiction and administration of the Provincial Governments and are

entrusted to the care of the Federal Governor It is evident that while the Government is in sympathy with the principle, difficulty has been felt as to the limits to which its application is a practical possibility The Under Secretary to the India Office (Mr. Butler) explained what those difficulties are. While mainly administrative, especially where 'pockets' of ab original tribes live among a more advanced population, they also entail the possibility of a retrocession where some cultural advance has already been made

LORD EUSTACE PERCY pointed out that it had not been possible to provide the House with the detailed information requisite for a decision on the detailed amendment of the schedule, and it is probable that the wisest course was followed in the adoption of the suggestion of the Attorney General (Sir T Inskip) to withdraw the question from immediate discussion by the omission of the schedule from the Bill and the preparation of an Order in Council for submission to the House after all necessary information had been obtained. Members thus have the assurance that they will at least be in full possession of the facts, and the "anthropologists" will be in a position to gauge how far it will be possible to avert the danger of oppression, which is feared, through clash of culture, under the Provincial Governments In the meantime, the important pronouncement has been made that the policy of the Government in dealing with the question of the aboriginal tribes is assimilation rather than segregation

Aborigines and the Law in Australia

IT is evident that public opinion in Australia has been stirred by recent decisions of the courts in criminal cases in which aborigines have been implicated Two aborigines undergoing sentence for killing a goat have been released from Port Augusta gaol, according to an Adelaide cable in *The Times* of May 7, by the Governor of South Australia, Major-General Sir William Dugan, in response to a petition from the Aborigines Friends Association It was stated that the crime was committed under stress of great hunger and in ignorance of the white man's laws This decision has renewed interest in the case of the two aborigines recently condemned to ten years imprisonment for killing a fellow-tribesman who had revealed ritual secrets. No doubt an effort will be made to secure some modification of the decision in this case also. These, unfortunately, are not the only cases affecting aborigines which have attained notoriety and caused misgiving as to the judicial procedure in dealing with crimes and misdemeanours of aborigines. They point to the need of a special tribunal and a penal code *ad hoc*, which will take fully into account aboriginal culture and outlook on life, property and society It is surely anomalous that while the Federal Government, for example, fosters continued tribal existence by securing to the aborigines the rights of access to traditional hunting grounds and water-holes, it forces them to abrogate tribal custom by submission to a code and tribunal appropriate to the civilisation and outlook of the white man

Excavations at Tell el-Amarna

IN the season's excavations of the Egypt Exploration Society at Tell el-Amarna, which have recently been brought to a close, the most notable achievement has been the completion of the exploration of the great palace of Akhenaten, or rather of what was left of it by the spoilers by whom it was destroyed at the collapse of the Aton religion and the abandonment of the city. The building was of a remarkable size It has now been shown by the recent excavation to have been little less than a kilometre in length At the south end was a vast hall in which the roof was supported by six hundred square pillars of mud brick. The walls had been covered with faience tiles in green with a characteristic decoration of inlaid white daisies Among the relics found in this building were a large number of fragments of huge statues These evidently had occupied a position along a plaster pavement leading to a columned hall. They had apparently stood on the oblong bases which were found at intervals along this passage. It is to be concluded that the statues were hacked to pieces when the palace was destroyed. Near the palace entrance was a well-preserved copper crowbar, which, no doubt, had been used as one of the implements of destruction. Among the examples of the sculpture, for which the site is now famous, this season's finds included a remarkably fine head of Akhenaten executed in black granite.

Bronze Age Burials near Bournemouth

A REMARKABLE example of a bronze age barrow is now in course of excavation at Dudsbury, near Bournemouth. Its method of construction is believed to be unique in the British Isles. Beneath the sand and gravel forming the surface of the heath on which it is situated, it is stated by a correspondent of *The Times* in the issue of April 26, that Col. C. D. Drew, who is conducting the excavation, has found a mound of turves, three feet thick at the centre No skeletal remains were found in this mound, which constitutes the primary interment For this, the acidity of the soil is held responsible, all animal remains being destroyed by its action. A secondary interment took place in the top of this mound, and above it was piled a further six feet of turves with a top dressing of other soil. In the secondary interment was an inverted cinerary urn which had covered the ashes of the incinerated body. It is of Middle Bronze Age type (*c* 2,000–1,500 B.C) and has an ornamentation of three horizontal grooves running around it and finger-nail marks on the rim. It is about 16 inches high and 12 inches in diameter. It will be deposited eventually in the Dorchester Museum.

Progress in Aero-Engine Design

THE Bristol Aeroplane Company has just completed the official tests of an improved engine, to replace the standard Pegasus III air-cooled radial

engine now in production This engine, known as the Pegasus X, gives an output of 920 horse-power at ground-level, and maintains 875 horse-power at 6,000 ft. altitude, with a remarkable weight of only 995 lb., completely equipped This figure of 1 08 lb per H.P. is the least weight/power ratio ever reached in a production type of aero engine, designed to stand up to the conditions of everyday use. The Rolls-Royce racing engine produced for the last Schneider Trophy race had a ratio of only 0 7 lb per H P., but this was not a production type The fuel consumption of the Pegasus X is also as good as any other type in existence, earlier air-cooled engines compared badly with contemporary liquid-cooled types in this respect It also standardises a controllable pitch airscrew, carrying the fittings for the hydraulic control gear integral with itself It is interesting to note the progress in weight reduction in aero engine practice since the adaptation of the internal combustion engine to flying requirements In 1903 the Wright Bros original engine weighed 12·7 lb. per H.P In 1913 the average was about 4·9 lb, while during the War period, 1914–18, rotary engines were produced as low as 2 5 lb The lowest weight to-day, previous to the new Bristol engine, was 1·15 lb per H P

Increase of Power Output in Aeroplanes

SCIENCE SERVICE, of Washington, D C., reports that, in future, U.S Army aeroplanes will be delivering approximately 70 per cent more power per pound of gasoline than was the case seven years ago In 1928 an increase of 33 per cent in power output was obtained by alteration of engine design to utilise 92 instead of 50 octane gasoline; and now a further increase is envisaged by the substitution of special lead blended iso-octane for the 92 octane gasoline Petroleum will still be used as a raw material in the production of this fuel, but the molecules will be 'torn down' and 'rebuilt' into new fuels The composition of such fuels will be half *iso*-octane, which is now being manufactured in substantial quantities by several refineries, and half good quality ordinary aviation spirit with the addition of 'ethyl'. The cost per gallon of the final product will be higher than that of present aviation fuels, but since its power per pound is greater it ought in the long run to prove more economical. The practical result of its utilisation will be to enable aeroplanes to fly farther and faster without increasing the weight of fuel carried

Parliamentary Science Committee

A MEETING of the general committee of the Parliamentary Science Committee was held at the House of Commons on May 14, Sir Arnold Wilson in the chair. It was reported that recent accessions to the list of bodies allied to the Committee include the Institution of Civil Engineers, the Institute of Chemistry and the National Veterinary Medical Association. In the period reviewed in the Honorary Secretary's report, special mention was made of the Committee's successful efforts to secure consideration of the claims of scientific research in connexion with the Metropolitan Water Board Bill now before Parliament Other activities reported included certain aspects of the Government of India Bill, the exemption from income tax of funds expended on industrial research, and the claims of science and technology to representation in the higher administrative posts in Government service Sir Arnold Wilson addressed the Committee and in his concluding remarks said "It will take time to evolve a suitable mechanism and a live organisation, but, if sufficient support is forthcoming and the membership widened to cover science as a whole, there is no reason why we should not be of real use and value to the nation, for it is in Parliament, and nowhere else, that the balance between science and ethics has to be settled, day by day, in terms of statutes and regulations".

British Postgraduate Medical School

H M. THE KING formerly opened the British Postgraduate Medical School at the L C C Hospital, Ducane Road, Hammersmith, on May 13 It will be recalled that the School arose out of a recommendation of a committee under the Earl of Athlone that London should have a centre for medical postgraduate work comparable with the great continental medical schools, which should be attached to the University and receive substantial Government support By the co-operation of the Government, the University of London and the London County Council, one of the hospitals under the last-mentioned body was allocated and specially enlarged and equipped for the purpose (see NATURE, April 21, 1934, p 600) Their Majesties were received by Sir Austen Chamberlain, chairman of the governing body of the School, who described its inception, stating that the School has three great tasks to enable general practitioners to become familiar with the latest developments in diagnosis and treatment, to provide instruction for graduates undertaking specialist studies, and to promote research and advance medical knowledge The King, in his reply, said that "The provision within the University of London of a new centre for clinical teaching marks a notable advance in the continuous effort of the medical profession to increase its capacity for service to mankind". He concluded by expressing the hope that "this school, with its happy union of ward and laboratory, university and local authority, drawing students and teachers alike from all parts of our Empire, and . from regions even more widely spread . . . [may] play an imperial rôle in the winning and dissemination of medical knowledge, in the relief of suffering . . and in enabling the doctors of all lands to come together in a task where all must be allies and helpers."

Mechanisation of Industry

IN an article in the Royal Jubilee number of *Engineering* published on May 3, Sir Richard Redmayne says that the mechanisation of industry tends to increase both the wages and the time available for leisure of the operatives, and thus increases their material welfare without the application of what are

known as 'revolutionary methods'. He illustrates this progress by what is happening in the coal-mining industry. The hewing of coal by pick and filling it into a tub by shovel, in a more or less confined space, is work of the most arduous nature The great expansion during recent years of mechanical coal cutters has made this work comparatively easy In 1900 only 1·5 per cent of the British coal output and 25 per cent of the output of the United States was cut mechanically In 1932 this had risen to 38 per cent in Britain and 68 per cent in the United States In the Ruhr coalfield the mechanical pick has found great favour, in 1913 only 2 2 per cent was cut mechanically, now 90 per cent is, 84 per cent being cut by mechanical picks and 6 per cent by mechanical coal cutters The transport of the cut coal from the coal face to the shaft bottom was almost as laborious as 'getting' the coal Now, owing to the perfection of electrically actuated plant, not only is the haulage on the main roads carried out electrically, but in the secondary roads also it is replacing horses and ponies So far as creation of wealth and increase of leisure and comfort of the mass of mankind are concerned, the engineer has taken a leading part During the last 130 years, wages in coal-mining have risen 3 2 times and the daily time of labour has been decreased 37 per cent, the return on the capital remaining on the average stationary. The chief beneficiary under the system of mechanisation has been the manual worker There is no doubt that the rationalisation of industry tends to decrease the number of employees, but Sir Richard Redmayne thinks that the lowering of the price of the commodity, its more effective distribution leading to the increase of new industries, together with the increase in wages and leisure creating an increased demand, will result in more than the absorption of the overplus of labour

Unemployment among Young Persons

THE International Labour Office estimates that of about 25 million unemployed throughout the world, about one fourth, or 6–7 million, are young persons less than twenty-five years of age In Great Britain the percentage between fourteen and twenty-four years old was 30·2 per cent in 1931, a figure which indicates the significance of the National Jubilee Trust inaugurated by the Prince of Wales The corresponding figure for Switzerland in July 1934 was 15 per cent, but for Hungary in 1930 it reached 42 per cent; in Italy in 1932, 41·5 per cent of the unemployed were between fifteen and twenty-five years of age. These figures indicate the quantitative significance of the discussions on unemployment among young persons at the International Labour Conference opening at Geneva on June 4 They do not, however, reveal the demoralising effects of prolonged unemployment, which are much more serious among young than among older persons. Steps already taken by various countries to deal with this position are indicated in a report prepared by the International Labour Office as a basis for the discussions. The report suggests that most of the measures to be taken to ameliorate unemployment among young persons call for pooling of experience rather than for the drafting of a convention Particular stress is laid upon the raising of the school-leaving age to fifteen years, the creation of an increased number of technical schools, the organisation of vocational training centres in connexion with public employment agencies and the establishment of centres for recreation, physical training, etc

Molecular Structure of Dielectrics

SIR WILLIAM BRAGG chose the molecular structure of dielectrics as the subject of the twenty-sixth Kelvin Lecture delivered on May 2 to the Institution of Electrical Engineers He pointed out that the properties of dielectrics depend on their composition and on the arrangement of their atoms and molecules During the past twenty-five years, men of science have used X-rays to study the structure of various substances, and engineers by other means have discovered many of the factors which govern the properties of dielectrics. It is now necessary that the two classes of workers should come together and pool their resources in making further advances It is sometimes thought that X-rays are only of use for examining the structure of crystals, but it has to be remembered that crystallisation is a property of all substances The crystal is used to obtain electron maps of the image of a single molecule and these maps enable us to find out the electron densities in its various parts. It is possible in many molecules to measure the exact distance from atom to atom, and to determine the way in which they are linked together to form the molecules. This method of attack can be used even when the molecules are not so definite in shape as they are in a crystal Sir William pointed out the analogies between the properties of proteins and those of dielectrics and laid stress on the recent work done at Leeds by Mr. W. T Astbury. Once the basic theory of dielectrics is determined, rapid progress will be made in practical applications. It is fortunate that the researches in the pure science of atoms and molecules and the many technical investigations now being carried on are feeling their way towards each other.

The New Commonwealth Society

ACCORDING to the annual report of the *New Commonwealth* for 1933–34, a clearer demarcation will in future be drawn between the research and propaganda activities of this organisation. Educational and propaganda work will be undertaken by the New Commonwealth Society, which will continue to be subdivided into an international section and the various national sections. Brief reports of the activities of all these sections are included, which indicate the extent to which the scientific study of international affairs is being encouraged in this way. The scientific investigations hitherto carried out by the Research Bureau of the International Section will now be carried out by the New Commonwealth Institute. These activities are guided by an Advisory Research Committee, which includes among its

members Major-Gen Sir F. Maurice, Brig.-Gen. E. L Spears, Prof. A. Zimmern, Prof N J. Baker, Prof H. V. Temperley, President N B Butler, M. Nicolas Politis. This Committee will advise upon research work on the principles of international relations, questions of international justice, law and equity, and problems of international security The publications of the Institute will include monographs and a quarterly review in English, German and French, and preparations are being made for the publication of a yearbook The work is largely carried out by means of circular letters, but it is also proposed to hold conferences twice a year in different centres A series of fortnightly 'round table' discussions has also been initiated

Training for Industrial Management

IN a report entitled "Three Years' Experience and Results in the Training of Scientific Men for Industrial Management" (57 Gordon Square, London, W C 1), Mr. W. R. Dunlop describes the work which he has carried out in providing facilities for training in this subject on the lines of personal and individual tuition, and more recently by correspondence The courses, he explains, were not undertaken in the expectation of obtaining spectacular results; but experience has shown that scientific and technical men are definitely interested, and that those who have taken full advantage of the training have derived substantial benefit in one way or another A difficulty has been to get something out of the students as well as putting something in. It has been hard to make chemists in particular understand that management is not a subject but an activity, and that action, energy and initiative as well as passive absorption of knowledge must be demonstrated in a course of training. Chemists in some cases appear to suffer from an 'inferiority complex' in regard to expressing opinions on matters outside their immediate province, while on the other hand many engineers, especially mechanical engineers, tend to go to the other extreme.

Public Health in British Colonies in 1932

THE fourth Supplement to the *Tropical Diseases Bulletin*, December, 1934, contains summaries by Dr. Harold Scott of medical and sanitary reports relating to the year 1932 from British colonies, protectorates, and dependencies The summaries give for each country the year's record of vital statistics, maternity and child welfare work, school hygiene, general sanitation, housing and town planning, etc, followed by particulars of the tropical diseases occurring in them, and the measures taken locally to combat them. The records show, on the whole, that in spite of retrenchments of medical staffs and curtailment of expenditure on public health services, the general health of the English communities has been well maintained, and no appreciable increase of sickness has occurred in the native communities Retrenchment has had the effect of bringing to the fore the question of the local training of natives for medical duties. In the Gold Coast, a scheme for the training of nurse-dispensers has been instituted, and elsewhere medical schools exist where native practitioners have been successfully trained

Ross Institute Industrial Advisory Committee

A MEETING of this Committee, at which the chairman, Mr G H Masefield, presided, was held on January 29 last at the rooms of the Indian Tea Association The meeting was addressed by Sir Malcolm Watson, who described some of the anti-malarial measures that have been undertaken in Southern Rhodesia, Beira and some of the Gold Coast mines, by Mr A Wigglesworth, who raised the question of malarial conditions on sisal estates, and by others. Dr Ramsay, of the Ross Institute in India, mentioned the 'eye fly', which is not only a nuisance but also a danger, as it transmits catarrhal conjunctivitis, and against which no effective measures are known except protection by means of wire gauze spectacles Sir Malcolm Watson directed attention to a booklet on the prevention of malaria which is distributed free to those residing in, or proceeding to, the tropics The Ross Institute, which is amalgamated with the London School of Hygiene and Tropical Medicine, is the medium through which industries in the tropics keep in touch with the work of the combined bodies and seek advice, and some £15,000 are required annually from voluntary subscriptions for propaganda work and appeals

Microscopes and Accessory Apparatus

IN the 1934 edition of the catalogue issued by Messrs Carl Zeiss (London), Ltd (37 Mortimer Street, London, W.1), after an excellent introduction upon the theory of the microscope, the series of microscope stands manufactured is described The design of the microscope stand has substantially altered in recent years, and the usual form now adopted consists of a broad base which supports a one-piece limb for carrying the illuminating system, the stage and the tube. This one piece limb is in the form of a segment of a circle with a deep central recess. This recess serves as a handle, and provides ample range for a large stage. Another convenient modern device is the inclined tube, single or binocular, which can be fitted to most of the models, in some of which the fine-adjustment head is located in the tilting axis A large range of Huygenian and compensating eye-pieces, and achromatic, fluorite and apochromatic objectives, are manufactured. Petrological and other types of special stands, magnifiers, hæmacytometers, micrometers, micro-manipulator, photomicrographic cameras and other accessory apparatus are also listed.

Research on Bird Migration

THE German Government has issued an announcement referring to the work of the German bird migration research stations—in Heligoland and at Rossitten—where rings are attached every year to the feet of more than 160,000 migratory birds. The rings are inscribed with identification numbers and with the address of one or other of the stations—"Vogelwarte Helgoland" or "Vogelwarte Rossitten"

respectively. The stations are anxious to receive reports of the finding of these birds in any part of the world with the view of gaining further information as to bird migration and other phenomena of bird life They will gratefully acknowledge all such reports, and are prepared to furnish in reply information not only as regards the bird in question, but also as regards their work generally Reports will be sufficiently addressed if directed to Vogelwarte Helgoland, Germany, or Vogelwarte Rossitten, Germany

Federation of Scientific Societies in Australia

THE Australian National Research Council, having come to the conclusion, at a general meeting last January, that it is not properly fulfilling its function as a national body representative of scientific thought and endeavour, will, during this year, examine the possibilities of effecting a federation of the various State Royal Societies, the Linnean Society of New South Wales, and a number of professional organisations such as the Australian Chemical Institute, the Institute of Physics, the Institution of Engineers and the Australian Veterinary Association The federation will be confined to bodies concerned with the physical and biological sciences No constitution has yet been suggested, but the general proposal is that each constituent member shall retain its independence as at present and shall have the right to representation on the Federal Council. The nature of the representation and the definition of duties of the council will be the subject of discussion at a conference of delegates from the interested societies, to be called later by the present National Research Council

Announcements

THE council of the Royal Society of Edinburgh has awarded the Makdougall-Brisbane Prize for the period 1932–34 to Dr A. E. Cameron, lecturer in entomology, University of Edinburgh, for his publications in entomology, including his recent paper in the *Transactions*, "The Life-History and Structure of *Hæmatopota pluvialis* Linné (Tabanidæ)"

THE Prime Minister will open a Noise-Abatement Exhibition at the Science Museum, South Kensington, on May 31 at 11 a m

THE annual meeting of the Swiss Röntgen Society will be held at Montreux on June 15 and 16 Further information can be obtained from Dr. A. Grosjean, La Chaux de Fonds, Switzerland.

THE sixteenth annual congress of the German Association for Microbiology will be held in Berlin on May 26–28, when the subjects for discussion will be diphtheria and piroplasmiasis.

FOLLOWING the announcement that the Australian Government will erect a laboratory in Melbourne for the Forest Products Division of the Council for Scientific and Industrial Research, Mr. W Russell Grimwade has offered to provide £5,000 for the purchase of additional apparatus and equipment for the new building

THE following appointments have recently been made by the Secretary of State for the Colonies Mr A M. Gwynn, entomologist, Agricultural Department, Nigeria, to be assistant entomologist, Agricultural Department, Uganda; Mr. H. R Binns, to be veterinary officer, Nyasaland; Mr R G. Sangster, to be assistant conservator of forests, Uganda, Mr J Gordon, to be inspector of plants and produce, Gold Coast

THE nineteenth National Baby Week will be held on July 1–7 The subjects for propaganda during 1935 will be the welfare of the pre-school child and the good nutrition of mothers and children On July 1–3 a conference on "Maternity and Child Welfare", organised by the National Association for the Prevention of Infant Mortality, will be held in London Further information can be obtained from the Secretary, National Baby Week Council, 117 Piccadilly, London, W 1

THE Institution of Electrical Engineers is making arrangements for a summer meeting to be held in Belgium, probably on September 8–14. The programme will include excursions and visits to works, and among the towns included in the itinerary will be Brussels (which will probably be the headquarters town and where the Exhibition will still be in progress), Antwerp, Charleroi, Dinant, Langebrugge, Liège, Tirlemont, and also Ypres and other places in the battlefields of the War.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned :—An assistant at the Coal Survey Laboratory, Nottingham —The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S.W 1 (May 20). A veterinary investigation officer at the University of Liverpool—The Registrar (May 24) A principal of the Technical College and School of Art, Colchester—The Director of Education, County Offices, Chelmsford (May 25) A science lecturer in the Yorkshire Training College of Housecraft, Leeds—The Director of Education Education Department, Colverley Street, Leeds (May 28). An assistant in the Natural History Department of the Royal Scottish Museum, Edinburgh—The Director (May 31). A lecturer in geography and geology at St. Luke's College, Exeter—The Principal (May 31). An assistant lecturer in applied electricity and hydro-electric engineering in the University College of North Wales, Bangor—The Registrar (June 8). A lecturer in geography in Armstrong College, Newcastle-upon-Tyne—The Registrar. Assistant engineers for the Drainage and Irrigation Departments of the Governments of the Federated Malay States and Straits Settlements—The Crown Agents for the Colonies, 4 Millbank, London, S W.1.

Research Items

Abyssinian Games. In the course of two expeditions to Abyssinia (1928–29 and 1932), M. Marcel Griaule collected notes on more than four hundred games and recreations of the Abyssinians, of which he has published a selection (Bibliothèque de l'École des Hautes Études. Sciences réligieuses, 49, Paris, Lib. Leroux, 75 fr.). They range from games involving the use of simple musical instruments and simple apparatus such as tops, balls, string, etc., to singing and dancing, games, rhyming, riddles and animal tales. Many of the games have a divinatory character, and it is noted that there is throughout Abyssinia a strong belief in the efficacy of children as agents of divination. Certain general principles are to be observed in the collection of games in Abyssinia. Between one district and another there may be a marked difference in the games played, or the rules of the same game may differ widely. The areas within which any variation obtains may be very restricted. In part this is due to the numerous strata of the peoples who have penetrated the country, and also to the consistent policy of the Abyssinians in enslaving and transporting peoples socially less highly organised than themselves. Further, the geographical configuration of the country is responsible for some variation, especially in those games which make use of plants. The high plateaux with their relatively cold climate are split up by low-lying valleys with a climate which varies rapidly in narrow zones from the relatively cold of the heights to tropical in the low lying parts. The vegetation varies accordingly and with it the character of the games in which it has a function. The variation of climate may also affect the character of the games in other ways. It is, therefore, not sufficient to study the games as distributed by provinces. Their investigation must be highly localised. A further discrimination must be exercised in accordance with the season; and in others the age and sex of the players has to be noted. The solemnity with which some of the games are played, and occasionally their long duration, as in the taboos of Carême, leave it beyond doubt that their origin is religious or magical.

Gulper Eels. The Carlsberg Foundation's oceanographical expedition round the world in 1928–30, and previous *Dana* expeditions under the leadership of Prof. Johannes Schmidt, have resulted in the acquirement of a vast amount of new and valuable oceanographical and marine biological data. Papers embodying the results of these various expeditions have appeared in a large number of scientific journals. Since the conclusion of the 1928–30 expedition, however, a series of special "Dana Reports" has begun to appear. These reports will continue to be published at intervals over a number of years and may be obtained from the Oxford University Press. *Dana* Report No. 3 on "Les Poissons Apodes apartenant au Sous-ordre des Lyomères" (the so-called gulper eels), by Leon Bertin, deals with the morphology, classification, and geographical distribution of the genera *Saccopharynx* and *Eurypharynx*. The relatively very comprehensive *Dana* collection of these fishes consisted of 5 individuals of *Saccopharynx* out of a total of 14 known specimens and of 59 *Eurypharynx* out of the 122 so far known. In the latter genus the author recognises (at least provisionally) two species, and in the former, four species, two being here described for the first time. The whole paper is based on the examination of adult fishes. A further memoir on larval and post-larval stages is promised.

Systematics of Rhizopoda. Henri de Saedeleer (*Mem. Mus. Roy. d'Hist. Nat. Belgique*, No. 60, 1934) divides the Rhizopoda according to the nature of their pseudopodia into three orders, the first two of which were already defined, Lobosa, Filosa and Granuloreticulosa, the third including Rhizopoda with filamentous pseudopodia which may exhibit many or few anastomoses and streaming of granules. This third order includes the suborder Athalamia, such as *Gymnophrys*; Monothalamia, for example, *Allogromia*, and Polythalamia, that is, the Foraminifera which are not included in this memoir. The characters of the further subdivisions—families, subfamilies, etc.—are followed by accounts of twenty-nine genera and fifty-eight species. From his studies on a large amount of living material from Belgium, from fresh water and from the seashore, the author has provided useful line drawings of most of the species. Four new genera and seventeen new species are described.

Empire-Grown Sisal for Marine Cordage. The Imperial Institute has recently published (February 1935. 1*s*.) a report upon tests carried out in conjunction with the Admiralty of tarred and untarred cordage made from East African sisal. As Manila hemp does not absorb tar satisfactorily, such cordage in the past has generally been made from European hemp. In order to investigate the effect of tarring on the durability of sisal cordage, the Admiralty has recently carried out a further series of experiments. Ropes, three inches in circumference, were prepared from East African sisal, one batch being made in the ordinary way from untreated fibre and another from yarn which had been passed through a bath of Archangel tar. Both kinds of rope were exposed to the action of sea water for periods of two, four, six and nine months, their breaking strain being determined at the end of each period. It was found that after exposure to the action of sea-water for nine months, the untarred sisal rope had lost 76 per cent of its initial strength, whereas the strength of the tarred sisal rope had fallen only 29 per cent. The tests have thus shown that the life of sisal ropes when exposed to sea-water is enormously prolonged by tarring. The Admiralty is therefore considering the general adoption of tarred sisal cordage in place of tarred European hemp cordage, and inquiries are being made as to the extent to which such substitution could be carried out.

A Disease of Pomegranate. A short paper by H. Chaudhuri and Jagtar Singh (*Trans. Brit. Mycol. Soc.*, 19, Part 2, 139–144, January 1935) describes a disease of pomegranate, *Punica granatum* L., in Lahore, India, caused by the fungus *Amphichaeta punicæ*, n. sp. Infected twigs bore numerous pycnial fruit bodies, and the tree was stunted, but seldom killed. Infection experiments proved that the causal fungus was a new species belonging to the genus *Amphichaeta*, for which the name *A. punicæ* has been suggested. Morphology, cultural characters, and the effect of various external factors on growth of the fungus are described.

An Earthquake Magnitude Scale It is usual to estimate the intensity of an earthquake in terms of some arbitrary scale such as the Mercalli or Rossi Forel The results may however be untrustworthy owing to variations in the nature of the ground the depth of the focus or in some cases to the origin being submarine In a recent paper (*Bull Amer Seis Soc* 25 1 32 1935) Mr C F Richter shows that a comparison of the maximum amplitudes recorded at different epicentral distances by the Wood Anderson torsion seismometers at the seven stations in South California makes it possible to estimate earthquakes as a whole in terms of a magnitude scale The magnitude of a shock is defined as the logarithm of the calculated trace amplitude expressed in microns with which the seismometer would register that shock at an epicentral distance of 100 km Such magnitudes can be assigned to the nearest half unit or less Shocks of magnitude 1 5 are just strong enough to be felt those of magnitude 4 5 may cause slight damage near the epicentre while those of magnitude 7 5 are at the lower limit of great earthquakes For example among recent Californian earthquakes that of Long Beach in 1933 was of magnitude 6 2 and that of Nevada in 1932 of 7 5

River Dee Flow Records The brochure recently issued by River Flow Records (Parliament Mansions Victoria Street S W 1) on the River Dee (Aberdeenshire) contains extremely serviceable information concerning the water levels rainfall and run off in the basin of that river for the year 1934 There are four introductory statements of an explanatory character dealing with the daily rainfall distribution the Woodend flow gauging station the Cairnton water level station and finally with the diagram records for the year The diagram records four in number with a prefatory map have been designed to obviate the publication of lengthy and numerous tables and each of them covers a period of three months The originals of the diagrams are 2½ times the scale of the plates and prints therefrom are stated to be available if required On the rainfall and run off diagrams the aggregate run off starts from zero on January 1 and amounts to 39 inches by the end of the year The aggregate of rainfall starts with a credit of 0 39 inch which is the minimum residual run off for the water level of January 1 under desaturated conditions The story of the year is briefly the desaturation of the early months shown by excess of run off merging into the evaporation losses of the later spring, followed by the high evaporation losses of the summer and re saturation losses of the early autumn and ending with a see saw of saturation and de saturation during the late autumn and winter There is an interesting appendix on the cost of river flow records showing that an annual expenditure of about £100 will cover the whole scope of the work for a fully equipped flow gauging station on rivers of 100 ft 200 ft in width This expenditure falls roughly in equal proportions under four heads interest on capital expenditure, maintenance observations and tabulation, compilation of completed records, publication

Combination Tones and Modulated Waves H Hazel (*Phil Mag* Jan 1935) has carried out some experiments which clarify the explanation of the famous Helmholtz König controversy on the objective existence of combination tones He shows that the addition of sinusoidal components whether these are sound waves or wireless waves does not produce combination frequencies unless the disturbances are impressed on a non linear system The multiplication of sinusoidal components (modulation) does give combination frequencies which can be detected by a linear arrangement and if two sinusoidal disturbances are impressed on a non linear system, product terms are found in the motion of the latter which correspond to a modulation and hence to the production of combination frequencies

Deuterium Content of Ordinary Water Both the H/D (hydrogen to deuterium) ratio in ordinary water and the question of the existence or non existence of the electrolytic separation of the oxygen isotopes have been subject to some doubt H L Johnston (*J Amer Chem Soc* 57 484 1935) describes the preparation of deuterium free water (less than 1 D atom to 10^8 H atoms) by electrolysis and density determinations by a totally submerged float The results correspond with an abundance ratio of 5750 ± 250 for H/D in ordinary water which confirms the figure of 5000 ± 500 obtained by the mass spectrograph by Bleakney and Gould The electrolytic separation factor for O^{16} relative to O^{18} was found to be 1 008 which proves the futility of attempting to prepare pure O^{18} or O^{17} by electrolysis From the H/D ratio of 5750 the atomic weight of normal hydrogen is calculated as 1 00795 on the O^{16} scale or 1 00770 or 1 00775 on the chemical standard of O 16 according to the abundance ratio of O^{18} of Manian Bleakney and Urey or of Mecke and Childs respectively These figures are based on Aston s figure of 1 00778 for H^1 and Bainbridge s value of 2 01363 for D It may be remarked that Ingold and Ingold have recently reported an abundance ratio of H/D of 9000 (NATURE 134 661 1934)

Piperidine the Alkaloid of *Psilocaulon absimile* C Rimington research fellow under the Empire Marketing Board reports the isolation of the toxic alkaloidal constituent of *Psilocaulon absimile* N F Br and its identification as piperidine hydrochloride (*S African J Sci* 31 184 Nov 1934) The Aizoaceæ of which *P absimile* is a member have on occasion caused the death of stock but the chemical investigation of their constituents has received little attention In the present investigation a straightforward acid alkali extraction process isolated the alkaloid, which was identified as piperidine by the preparation of the picrate aurichloride and platinichloride The picrolonate was also prepared The pharmacological action of the salts on rabbits and frogs confirmed the chemical identification The investigation has both chemical and botanical interest since piperidine itself has not hitherto been found as a naturally occurring plant alkaloid But the importance of the work lies in its possible economic application and in the additional evidence it provides of the wisdom of the policy of subsidising research which the Empire Marketing Board adopted One pound of piperidine can be obtained from 10 kilos of the dried plant with the aid of such cheap chemicals as caustic soda, hydrochloric acid chloroform and light petroleum. Piperidine has certain commercial uses and the high cost of the synthetic substance offers scope for the commercial production of the natural alkaloid from *Psilocaulon* It may be no more than a coincidence that the list price quoted in the paper is £6 8s 0d a lb while to-day it may be obtained for £2 9s a lb

Cost of German Scientific Publications

THE high prices of German scientific publications, to which reference has been made in NATURE (132, 34 and 540, 1933), are again discussed in *Angewandte Chemie* of March 9. The chief factors in the increased cost are the decreased demand, increased cost of paper, binding, type and setting and illustrations, as well as overhead charges, decreased revenue from advertisements resulting from diminished circulation, the publication of smaller editions to avoid getting out of date, with consequent heavier on costs, and the high discounts afforded to German booksellers. It is asserted that every effort is being made at compression to compensate for the 15–20 per cent greater space normally required for a German book as compared with the same work in French or English, and that the 'Munster Agreement' of 1933 (between librarians, publishers and the university unions, representing the authors) has in this way already resulted in an estimated decrease of 2,000,000 gold marks in costs of publication.

The prices of books and journals have been reduced, but only exceptionally has the cost per page been reduced, chiefly due to the technical costs of production which are not under the publisher's control. It is estimated that the cost of setting and printing is about 95 per cent above that of 1913, plates and line blocks are 60 and 150 per cent dearer, paper 12 per cent and bookbinding 100 per cent above the 1913 charges, representing an average increase of 50 per cent, or more for many important books. Author's fees have also increased, but are being reduced, and are now little above the pro-War figure. This factor, however, reacts adversely on the demand, since authors form an appreciable proportion of the purchasers of scientific works. During 1934, imports of foreign journals into Germany decreased 16 per cent in volume as against 12 per cent by value, indicating increased costs of production elsewhere, while exports of German literature decreased by 13·1 per cent in volume and 16½ per cent in value, indicating a fall in German prices.

On-costs in particular have increased both actually and relatively, and are still tending to rise owing to industrial conditions and diminished output. Publicity charges are more than 50 per cent higher than in 1913, taxation is at least four times as great, rents are 20 per cent, heating and lighting 27 per cent higher, and 20 per cent of the turnover in advertisements has to be contributed to the trade council. Postage charges are about 20 per cent higher and for such journals as *Angewandte Chemie* and *Die Chemische Fabrik* amount to 15 per cent of the total cost of publication. Salaries and wages are estimated at 25–100 per cent above the 1913 level. The size of editions is one of the most difficult problems confronting the publisher. Profits can only be made on sales in excess of a certain minimum, and to promote sales by diminishing costs, endeavours have been made to issue new editions of textbooks every seven or eight years instead of three or four years, but there are limits to such efforts imposed by the rapidity of scientific developments. Foreign sales have diminished enormously for political reasons as well as through increased competition, and for reasons similar to those operating internally. Advertisement revenue has assisted considerably in the reduction of the price of certain journals of applied science, but only amounts to about one third of the revenue from this source in 1929–30. Retail and wholesale booksellers in Germany demand a 25–30 per cent discount as against 15–16⅔ per cent abroad, and the trade is overcrowded. The reduction in the average price of German books from 8.36 to 4.32 gold marks in four years is largely due to the special cheap editions issued by the million, and is not reflected in scientific books, the purchasers of which have been heavily hit financially.

Increased purchasing power, decreased taxation and costs of production with further efforts at condensation are the only hopeful means of increasing the circulation. The American proposal to publish only the more important scientific papers, retaining the majority in manuscript and providing photostats as required, is severely criticised as fatal to publication of scientific knowledge and its effective circulation.

Copepods from West Greenland Waters*

AN important collection of pelagic copepods is described by Dr. P. Jespersen from the waters west of Greenland in the Davis Strait and Baffin Bay, with one station to the south-west of Iceland. The submarine ridge across the narrow part of the Davis Strait with a maximum depth of 700 metres forms an effective barrier to the migrations into Baffin Bay of many Atlantic species the habitat of which is deeper than this; the depths to the south of the ridge exceeding 3,500 metres and the depths in Baffin Bay amounting to at least 2,000 metres. Warm Atlantic water predominates in the sea area south of the Davis Strait, but along the west coast of South Greenland the East Greenland polar current makes its way round Cape Farewell, and in the most western part of this area there are several stations, taken by the expedition, situated in the cold Labrador current.

A part of the Atlantic water passes over the submarine ridge in the Davis Strait and up into Baffin Bay, where it forms an intermediate layer below the surface with a positive temperature. The bottom water of Baffin Bay has on the contrary a negative temperature of about − 0.4°. The temperature conditions alone thus form a natural limit to the northward advance of certain species.

The species are divided into two main groups: those which are found in the whole area investigated and those which are exclusively, or to a predominant degree, found in the waters south of Davis Strait, 23 species being found in the first and 76 species in the second division. Davis Strait thus appears to form the northern limit of distribution for a large number of Atlantic species, and it is specially those found in fairly great depths that cease to penetrate northwards and those more frequently caught in the upper layers which occur in the whole area. Most of the species are oceanic and no species were found

* Meddelelser om Grønland udgivne af Kommissionen for Videnskabelige Undersøgelser i Grønland. Bd. 79, Nr. 10: The Godthaab Expedition 1928—Copepoda. By P. Jespersen. Pp. 166. (København: C. A. Reitzels Forlag, 1934.) 8.00 kr.

which in a pronounced degree are restricted to the Arctic sea areas Indeed Dr Jespersen states that "it is certainly a question whether among the oceanic copepods there are any distinct arctic forms at all"

The most frequent species were *Calanus finmarchicus*, *Calanus hyperboreus*, *Metridia longa* and young stages of the genus *Pareuchaeta* *Calanus finmarchicus* predominates in the hauls from the south of Davis Strait and the numbers are considerably reduced in Baffin Bay In Smith Sound, much farther north, it is again abundant in the surface layers *Calanus hyperboreus*, which likes cold water, is found only in small quantities south of Davis Strait, in the Strait itself in the upper layers being more abundant and in Baffin Bay present in small quantities *Metridia longa* occurs in small quantities south of the Davis Strait and in the upper layers of the Strait itself, but occurs in fairly large numbers in Baffin Bay. *Pareuchaeta* in its young stages is found in the water south of Davis Strait and only in small quantities in the Strait itself and in the more northern parts investigated.

Details of distribution and biology of all the species are given whenever possible with much interesting information, and many species are shown to have a more northerly distribution than was known before. A series of tables and curves is also provided One new species was found, *Euchaeta Wilsoni*, and this is represented by only one specimen

All-Metal Radio Receiving Valves

IT will be recalled that about two years ago the 'Catkin' series of receiving valves was first produced in Great Britain (see NATURE, 131, 735; 1933) In the construction of this valve, the amount of glasswork was reduced to a considerable extent, the upper portion of the envelope being formed of the cylindrical copper anode, which was sealed to the lower glass portion by a vacuum-tight joint Now, an entirely new series of literally all metal receiving valves is announced by the General Electric Co of America, and brief details of these were given by the New York representative of the *Wireless World* in the issue of that journal of April 19 These new valves employ a cylindrical outer shell of steel or iron welded to a metal base which rigidly supports the electrode system The lead in wires from the electrodes are strung through beads of glass, which are then placed in eyelets of a new alloy known as Fernico, which lines the holes in the base of the valve The assembly is then passed through a gas flame which fuses the glass beads so that they fill the eyelets Fernico is an alloy of iron, nickel and cobalt which has the same coefficient of expansion as the beads of glass employed, so that the seal is accomplished without setting up strains in the fusing process After the electrode system has been attached to the leads, the metal outer shell is placed over the structure and welded to the base The valve is now exhausted through this metal tube, which is then clamped, welded and cut off at the appropriate time

The use of an all metal construction enables the valves to be made smaller in dimensions than existing glass valves, with corresponding reduction in lengths of leads and inter-electrode capacitances The valves may therefore be of higher amplification factors without instability, and should retain their efficiency at shorter wave-lengths than existing types Further, since the metal shell completely surrounds the valve and is maintained at earth potential, there will be no necessity for shielding the valve after it is placed in its socket in the receiver. At the present time, six types of all-metal valve have been put into production at the R C A Manufacturing Co, which will make the valves for the General Electric Co It is expected that new receivers designed round the metal valve will be produced by the autumn of this year

Physical Methods in the Study of Earth Structure

THE increasing specialisation of science and its literature inspires an ever-growing demand for expositions of separate branches in terms suitable for workers in other fields. The effort to prepare such accounts is often beneficial to those who provide as well as to those who hear or read them, but some stimulus for their provision is needful, and notable among the available effective stimuli are the endowed annual lectureships of such bodies as the Institution of Civil Engineers. This is well exemplified in the forty-first James Forrest Lecture, delivered to that Institution on May 7 by Prof O T Jones, who took geophysics as his subject

The choice by a geologist to lecture on geophysics might in past years have led to a passionate or scornful attack on the geological ignorance of geophysicists, but even in this age of tolerance, Prof Jones is notable among geologists for his sense of the importance of physical methods in studying the problems of the earth He has, in fact, produced an admirably clear account of the subject, after modestly disclaiming any rôle save that of the exponent. So calm is the 'atmosphere' of his address that the geophysicist may even feel a craving for at least some more distinctively geological criticism or flavour But in the closing part of the address Prof Jones made a most interesting reference to a British problem that is of interest alike to geologists, geophysicists and engineers.

In many parts of the British Isles, Prof Jones stated, there are known to be many deep rock channels that are so filled with various materials that their existence has not been suspected until engineering explorations for railways, roads, tunnels or sites for reservoirs have revealed them Some of them are known to be post-glacial, others, being filled with glacial drift, must be pre-glacial It is still uncertain whether these latter are due to normal river erosion, in which case their gradient must have been continuously downward to the sea-level of their period, or whether they have been excavated by streams flowing below the ice, in which case they

may be deep narrow channels with a rising gradient both ends Several of these channels are known in East Anglia, one seems to commence a few miles south of Cambridge, and follows approximately the line of the L N E R to Bishop's Stortford at least as far as Newport It deepens rapidly southward, and if it is a normal river channel it must somewhere enter the sea, possibly following the Lea valley into the Thames estuary If so, it might cause grave difficulty to engineering projects (as other such channels have done elsewhere), like that for a Thames tunnel east of the Lea valley The buried channel of the Thames higher up is well known, but if the Newport channel does indeed enter the Thames estuary, its depth below sea-level would far exceed that of the known channel It would therefore be of great interest both to geologists and engineers if such channels could be detected with certainty by geophysical methods

The lecture briefly describes such applied geophysical methods, after discussing the scope of geophysics and the history and present position of the main 'pure' problems of geophysics It should be added that the term geophysics is used in the lecture in a restricted sense and such a remark as "geophysicists in this country do not concern themselves very much with the electric and magnetic field of the earth, which are observed in detail in various observatories", and the mention of the Carnegie Institution's Geophysical Laboratory without reference to the same Institution's great Department of Terrestrial Magnetism, must be interpreted as betokening unfamiliarity born of lack of personal interest in these further fields of geophysics

History of Bitumen

TO DAY, when petroleum with its vast range of derivatives is regarded as indispensable to the welfare of man, it is wholesome to be reminded of the salient factors which gradually extended its usefulness during the course of some five thousand years It is equally salutary to have delineated handicaps of lack of knowledge, apparatus and facilities, which nevertheless were minimised by the ingenuity of ancient peoples who employed bitumen for a variety of purposes still recognised to-day

A booklet entitled "The Story of Bitumen" (presumably by R J Forbes of Amsterdam, who last year contributed a similar article to the periodical *Bitumen* entitled "Aus der ältesten Geschichte des Bitumens") recently issued by Shell-Mex, Ltd., gives a brief account of the exploitation of bitumen from earliest records of its existence to about A D 1800 Abundant deposits were known even to the most ancient civilisations inhabiting the region between the Nile valley and that of the Indus, but production was necessarily confined to surface operations by lack of knowledge of the technique of deep drilling and absence of geological information on deeper oil or rock-asphalt deposits At the end of the period reviewed, in spite of vicissitudes which hindered rather than accelerated growth of the industry, particularly at the time of the later Roman Empire, the majority of deposits of which we now have knowledge were actually known Then, however, the importance of petroleum was negligible compared with present-day values, for the internal combustion engine which was later to give such tremendous impetus to the industry and create such a widespread demand for petroleum products was not yet discovered

Records of actual production in ancient times are naturally scanty It is obvious, however, that methods were extremely crude, as it is authentically reported that bitumen was recovered from the Dead Sea by men in rafts who simply 'hacked off' as large a piece of the floating mass as they could conveniently carry away Similarly, until the eleventh century, only the most primitive attempts towards distillation were made, and this fact virtually excluded the use of light combustible oils Gradually, however, more elaborate and practical methods were evolved, until at the beginning of the nineteenth century it may safely be said that the foundations of modern distillation technique were laid. Even so, no appreciable growth of the industry took place until after 1860, when deep drilling came within the realms of possibility It is surprising, therefore, that in spite of all these handicaps and difficulties to easy production, we find bitumen was used extensively in antiquity as a building and road material, as a waterproofing agent and in various guises as a weapon in times of warfare In comparatively recent times it was universally used also for lighting and heating purposes and as an ingredient of paints

The booklet, in addition to tracing the story of bitumen, gives a chronological list of outstanding dates in the history of bitumen and includes a bibliography on petroleum and bituminous materials which, together with the numerous excerpts from early works quoted in the text, should provide a useful background to a historical study of the petroleum industry

University and Educational Intelligence

BELFAST —Dr H Barcroft, lecturer in physiology at University College, London, has been appointed to the Dunville chair of physiology in succession to Prof T H Milroy, who is retiring on October 1

Dr D C Harrison, lecturer in biochemistry in the University of Sheffield, has been appointed to the J C White chair of biochemistry, in succession to the late Prof J H Milroy

Colonel S H Browne, formerly of the Indian Medical Service, has bequeathed to the University £10,000 to found medical research scholarships

CAMBRIDGE —The Royal College of Veterinary Surgeons has intimated to the Vice Chancellor that candidates who submit evidence that they are graduates in the Natural Sciences Tripos and that in the course of their examination they have passed in physiology, pathology, biochemistry and anatomy, may be exempted from the second examination conditionally on their passing the prescribed examination in animal management before the third examination

At St John's College, F. J S Hollick has been elected into a fellowship

OXFORD —The Halley Lecture will be delivered on June 5, at 5 p m in the Lecture Theatre at the University Museum by Dr J S Plaskett, director of the Dominion Astrophysical Observatory, Victoria, B C., Canada, who will take as his subject "Dimensions and structure of the Galaxy"

Mr. J. N L Baker has been appointed University reader in historical geography for seven years from October 1 Miss B M Blackwood has been

reappointed university demonstrator in ethnology for one year from October 1.

A reader in statistics is to be appointed for five years from the first day of Michaelmas Term, 1935, the warden and fellows of All Souls having undertaken to provide a stipend of £600 a year for that period

In continuation of his course of lectures on the scientific contributions of members of the Oxford colleges, Dr R T Gunther, reader in the history of science, in a recent lecture directed special attention to the work of Robert Plot, John Radcliffe and Edmund Cartwright, all of University College, and respectively a great natural historian, a most munificent benefactor and an eminent inventor At the same time the lecturer expressed his regret that the present Radcliffe Trustees should not have considered it their duty as managers of a charitable trust to preserve intact the historical scientific library of Prof Stephen Rigaud, which they had purchased for far less money than it has now realised in a public sale-room

UNEMPLOYMENT among young university graduates formed the subject of the deliberations of the Committee of International Students' Organisations at its meeting on April 10 11 As regards the possibilities of limiting the attendance of students at universities, the Committee urged that it would be both harmful and dangerous to endeavour to place restrictions on those who could rightly claim to attend the universities, and it disapproved of the imposition of a bar against women or against certain classes of the population on grounds of race or opinion As a remedy for unemployment among intellectual workers, it recommended the establishment of university and professional information centres in the various countries, and suggested that public authorities or mutual aid societies should undertake the direction of certain branches of intellectual work for which private individuals have not the means to provide Further, it suggested the adoption of measures by universities or student organisations for training young intellectual workers for their professions in country districts or colonies such as the 'social groups' in France, the 'educational missions' in Spain, or the 'frontier colleges' in Canada. Another recommendation was that bilateral or plurilateral agreements should be framed regarding the equivalence of university degrees, the exercise of professions abroad, and the employment of intellectual workers in foreign countries The Committee urged international organisations of students and intellectual workers to consider the possibility of establishing an international organisation for securing work on the basis of the general information which might be supplied by the International Labour Office.

Science News a Century Ago

University of London

On May 18, 1835, *The Times* said, "Yesterday the annual distribution of the medals and prizes to the successful candidates in the medical and surgical departments took place at the London University; Lord Nugent presided on the occasion . . Immediately after the distribution of the prizes the Chairman rose and addressed the company. His lordship had been about three years from London. At his departure the London University was in a state of infancy, at his return he had been highly gratified on finding that it had made so rapid a growth towards maturity Mr Thomas Campbell, who had first suggested the foundation of the present establishment, had said, that only two capital cities of Europe had been without universities, London and Constantinople The reproach was now removed from London, in which two most useful institutions flourished, not in a spirit of opposition to each other, but in a spirit of laudable emulation and generous rivalry"

Progress of Mechanics' Institutions

At the anniversary meeting of the London Mechanics' Institution (now Birkbeck College) held on May 20, 1835, the president, Dr Birkbeck, is reported to have said that "This establishment was still flourishing, and those elsewhere were becoming more numerous and more prosperous. The most remarkable circumstance connected with the prosperity of mechanics' institutions was the establishment of one at Cambridge, which had received the approbation and patronage of all the great and the wise of that distinguished seminary of learning Endeavours had been made to establish a mechanics' institution at a place near Bolton, but he (Dr Birkbeck) had received a letter from the person who made the attempt, stating that the mean rate of wages was only 7*s* a week, and although the subscription had been dropped from 10*s* a year to 6*s*, he could get no subscriptions, nor any donations At Manchester and Liverpool, however, the progress of these institutions had been great The number of members belonging to the metropolitan institution was 1,123, exclusive of honorary members, that of Manchester, including honorary members, was 1,232, and that of Liverpool including honorary members, was 1,206"

Theory of Respiration

At a meeting of the Royal Society on May 21, 1835, Dr William Stevens read the concluding portion of his paper on observations on the theory of respiration After reviewing the author's remarks on the interaction of the air and the blood and the experiments with which the paper was accompanied, the report in the Society's *Abstracts* said: "According to these views it is neither in the lungs, nor generally in the course of circulation, but only during its passage through the capillary system of vessels, that the blood undergoes the change from arterial to venous; a change consisting in the formation of carbonic acid, by the addition of particles of carbon derived from the solid textures of the body, and which had combined with the oxygen supplied by the arterial blood; and it is by this combination that heat is evolved, as well as a dark colour imparted to the blood. The author ascribes, however, the bright red colour of arterial blood, not to the action of oxygen which in itself is completely inert as a colouring agent, but to that of the saline ingredients naturally contained in healthy blood On arrival at the lungs, the first change induced in the blood is effected by the oxygen of the atmospheric air, and consists of the removal of the carbonic acid, which had been the source of the dark colour of the venous blood; and the second consists in the attraction by the blood of a portion of the oxygen, which it absorbs from the air and which takes the place of the carbonic acid."

Art in Modern Industry

THE attention which has been given in recent months to industrial design and the relations between art and industry has an important bearing on other profound problems of the machine age In spite of their efforts to foster healthier relations between creative design and craftsmanship, Ruskin and his school must take a large share of responsibility for the belief that a machine could not produce a thing of beauty While explaining that the wisdom of art consists in its unselfish devotion to the service of man, while insisting on the necessity for providing elements of beauty in the surroundings of the workman, and that art does its duty "in completing the comforts and refining the pleasures of daily occurrence and familiar service", Ruskin brought a somewhat rigid conservatism to bear on the use of new materials in art, particularly the use of metals

This attitude to the products of mechanical industry is rapidly passing, and even the most fleeting visit to such an exhibition as the British Industries Fair reveals the extent to which methods of mass production are now providing us with things of intrinsic beauty alike in plastics, textiles and many other fields Particularly is this to be observed in relation to the new constructional materials with which science is providing the building industry, the significance and utility of which are only now beginning to be realised by the public

These new materials are now finding expression in new forms adapted to their own inherent qualities and the specific and sometimes novel needs of the community to-day They are not being impressed rigidly into those forms in which craftsmanship of the past expressed the beauty and utility of older materials The significance of this point can scarcely be over-stated In fact, Ruskin's objection to the use of iron in architecture was to the use of iron in the way in which stone had been used in the past, rather than to its use in new ways adapted for the expression of its own valuable qualities It would be difficult to adduce from his writings objections which could be validly advanced against the form which the use of steel in structural work is taking to-day.

We are, in fact, witnessing to-day the escape of industrial design from the fetters of the past, and an impetus is being given to the creative instincts

the full effect of which is far from being felt The manufacturer is now concerned less with imitating the past than with discovering new methods of artistic expression for the new powers and materials Industrial design has acquired a new significance, none the less important because it permits the production of beautiful and artistic objects by the thousand or ten thousand where the old individual craftsman could turn out only units or at most dozens It affords an opportunity of expression to these creative instincts of man which is akin to the opportunity afforded in the scientific researches that have provided industry with the new materials upon which such design is executed

The reaction of science upon industry thus itself ensures that industrial art shall be dynamic Design is influenced as much by the materials and methods at its disposal as by taste and education, and failure to respond to the resources in the way of new materials placed at its disposal by the development or adaptation of technique, can be as disastrous as failure to respond to æsthetic considerations, or lack of sympathy with the spirit of the age in which the designer or craftsman works.

Industrial design is thus more than the application of art to a product in accordance with the inclination of an artist. It goes deeper than the sketching of graceful lines and masses The industrial designer must understand the desires and fancies of the public, whether as a result of careful surveys or constant familiarity with the qualities in an article which promote sales. He must not only be familiar with the relative advantages and disadvantages of the similar and competitive articles on the market but also understand something of the possibilities and limitations of the factory where the article is manufactured. For him the skilful selection which constitutes art depends as much on research as the manufacturing processes resulting in the article to which the designer's art is applied

Under modern conditions, therefore, the task of the industrial designer has become ever more complex, and indeed almost insoluble except when he works in close alliance with the scientific worker as well as the artist. Only from science can he acquire full understanding of the properties of the materials of industry and the processes by which they are worked; for upon this knowledge alone can be based a technique and resourcefulness in design capable of giving full expression to the possibilities of the materials or the highest satisfaction to man's artistic and æsthetic requirements. The note of service is as dominant in art as in science and is indeed one of their strongest links.

The improvement of industrial design and the development of closer relations between art and industry do not depend upon the manufacturer's efforts alone Many of the industries concerned are traditional and dominated by the outlook and spirit of craftsmanship, with all its inherent advantages and defects. In such industries, side by side with the scientific worker's task of determining, by tactful and harmonious co-operation, the basic principles underlying traditional practice, sometimes of centuries standing, there is the task of assisting the craftsman to adapt himself to changed materials and changed conditions The very strictness with which in the past the members of a craft have guarded their organisation, no matter how high their ideals of service or individual efficiency, has discouraged receptivity of new ideas and adaptation to new conditions

This position is the more serious when—as to-day—under the influence of science, new materials and new techniques are being created which are outside the traditional experience of the craftsman and for which that experience affords little or no guidance The essential task is thus one of education—of assisting the craftsman or designer to acquire the knowledge which will enable him to cope with the new conditions and use the new materials, while safeguarding the individual instincts and ideals of craftsmanship which inspire the finest work. In certain industries, such as building and decorating and the paint industry, such educational work is urgently required. Increased facilities in connexion with the teaching organisations with which such crafts are already equipped, for the systematic demonstration, examination and handling under practical conditions of the new materials now available, are highly desirable if the average craftsman is to be kept abreast of current scientific developments in industry affecting his occupation.

Developments along these lines should be of advantage to the manufacturers of the newer materials, as well as to those who use them and the public for whom the craftsman works. The lack of personal knowledge of the average painter or builder, for example, of many of the new pigments, oils, resins, diluents, plastics, etc., not merely hinders the artistic use and development of the new products, but also prevents the craftsman

adopting the critical and independent attitude that he adopts to the old and more familiar materials of his craft Only slowly can he acquire the practical knowledge which at once frees him from dependence on manufacturers' recommendations and then permits the skilful selection which is the essence of art

To some extent no doubt, developments in the training of those entering traditional industries or occupations may lead to a more scientific outlook and to greater receptivity to new ideas With the present rate of industrial change and development, however, the need for practical experience of the new materials upon which we have touched will persist The craftsman cannot work with new materials without experience of them, however ready he may be to adopt them in his work, and however much we may do to improve the facilities for the collection and dissemination of modern technical knowledge, or the scientific and technical side of the training of the recruits for such occupations, it is only with the co-operation of the producers of the new materials that the qualified craftsman can acquire the experience which enables him to transmute them into the forms most adapted for everyday service in designs satisfying man's artistic as well as his material demands

The question of utilising for the widest purposes of society the qualities and advantages of the new materials with which advancing technical and scientific knowledge has endowed mankind is thus not to be solved by the efforts of one class of workers alone It demands the skill of the craftsman and artist, the technique and method of the scientific worker, whether in academic or in industrial work, the patience and inspiration of the teacher and the appreciation of the public for beautiful and serviceable things Only as these are in harmony can the finest results be achieved, and in each there must be not the wanton discarding of that which is old but the skilful discernment between the old and new, based on definite knowledge which can select the most appropriate material or method for the purpose In all this there is no room for blind prejudice The frank acceptance of change, and the willingness to face all it means, are no less the secret of the development of new industrial art than they are of mankind's capacity to evolve a new order of society competent to handle the dangers and difficulties of the present age

Reviews

Himalayan Geography and Geology

A Sketch of the Geography and Geology of the Himalaya Mountains and Tibet By Col S G. Burrard and H H Haydon. Revised by Colonel Sir Sidney Burrard and Dr. A M Heron Pp x+359+xxxii+65 plates (Delhi · Manager of Publications, 1933.) 28 rupees, 43*s* 6*d*.

THE original edition of this work, which appeared in 1908, was intended to mark the centenary of the first expedition sent to the Himalaya by the Survey of India for geographical purposes, having for its immediate object the exploration of the source of the Ganges. After just a quarter of a century, a second edition has been brought out. During these twenty-five years a great deal of detailed exploration of the region has been accomplished and much new ground has been broken

The book is divided into four parts dealing with (1) the high peaks of Asia, (2) the principal mountain ranges of Asia, (3) the rivers of the Himalaya and Tibet and (4) the geology of the Himalaya.

When the high peaks are classified, it is found that of those the heights and positions of which have been determined by the Survey of India, there are no less than 135 more than 20,000 feet high There is an interesting discussion on the errors of the adopted value of the heights of peaks. In the case of high mountains it has not been possible to observe reciprocal angles, that is, observations cannot be made from the peak itself on account of the physical difficulty involved in transporting instruments to the top On this account we have to depend for accurate results on the assumption of a correct coefficient of refraction, since refraction, among other sources—for example, the deviation of gravity—is liable to produce the greatest error An interesting detailed analysis is given of the height of Mount Everest and other high summits as obtained from the several stations of observation, the object being to show the degree of uncertainty attached to heights of great mountains by the limitations imposed on the surveyor Since the first edition a great advance has been made in our knowledge of the effects of atmospheric refraction, due to the investigations of Dr de Graaff Hunter, who has worked out a value for the coefficient dependent

on height, temperature and pressure Tables for use with this method are found in "Auxiliary Tables of the Survey of India", Part iii

How a region, once undoubtedly under the sea, is now occupied by great mountain ranges, still remains without a satisfactory explanation The elevation of the Himalayan Mountains appears to be due to the folding of the earth's crust, under the influence of a tangential force acting from the north, raising the floor of the Tethys sea which covered this area in past geological times This folding was accompanied by the welling-up of granite and gneiss from the interior which now forms the main core of the great ranges Concurrent with elevation, erosion was at work producing the complicated and confused masses we see to-day The most potent cause of mountain building may have been the contraction of the earth's core, and the consequent wrinkling of the crust in attempting to accommodate itself to a smaller interior However, to every theory which has been propounded objections have been raised on the ground of inadequacy of any known cause The tectonic action is probably going on still, as evidenced by frequent earthquakes

It is of interest to note that the conspicuous light brown band of rock at the base of the final pyramid, so well known from the pictures of the Mount Everest expedition, is not a sill of granite but is really calcareous sandstone The final pyramid is composed of dark calc-schist

The great rivers of the Himalaya present also a difficult problem There is scarcely a mountain range in Asia that has not been cut across by a river Nearly all the rivers rise behind, that is to the north of, the ranges, which they cut through more or less at right angles on their way to the plains of India A remarkable feature is that when a river breaks from a trough, the range which is pierced is generally the higher of the two, also the gorge where the break through takes place is often situated near the highest point in the neighbourhood Probably more than one cause has been at work to produce these remarkable results One can imagine the rivers as serving the primeval drainage when the floor of the Tethys sea first emerged as dry land When subsequent wrinkling of the crust took place the rivers were able by erosion to maintain their courses, modified, no doubt, by the inequalities of elevation and the necessity for having to seek lines of least resistance.

Part iv is devoted to the geology of the Himalaya and is from the pen of the late Sir Henry Hayden of the Geological Survey of India. We have only space to mention one point of interest to which attention is directed That is the "main boundary fault" It extends the whole length of the Himalaya from Jammu State to Assam It is a reversed fault along which the older rocks have been thrust over the younger It has particular practical significance as it is in its proximity that at least three serious earthquakes have occurred within the last forty years, the most recent being the Bihar earthquake of January 1934 This seems to show that the thrusting and folding forces are still at work Where, for any reason, resistance is offered to this action, building up occurs of stress conditions, which eventually cause a breakdown of the material with a resulting earthquake

One of the original authors, Sir Sidney Burrard, has taken part in the revision, but the other, Sir Henry Hayden, was unfortunately killed on the Alps by a rock-fall in 1923 His place has been taken by Dr A M Heron, of the Geological Survey of India

All who are interested in the Himalaya, or contemplate travelling there, will find this work indispensable as a book of reference No other publication treats of the region from the same points of view The treatise is profusely illustrated by maps and diagrams H. L C.

Mathematics and Logic

(1) *A System of Logistic* By Dr Willard Van Orman Quine Pp xi+204 (Cambridge, Mass Harvard University Press, London · Oxford University Press, 1934) 20*s* net.

(2) *The Nature of Mathematics a Critical Survey* By Max Black (International Library of Psychology, Philosophy and Scientific Method) Pp xiv+219 (London Kegan Paul and Co, Ltd, New York. Harcourt, Brace and Co, 1933) 10*s* 6*d* net.

(3) *Idealistic Logic. a Study of its Aim, Method and Achievement* By C R. Morris Pp. ix+338 (London. Macmillan and Co, Ltd, 1933) 12*s* 6*d* net.

THE number of those who still believe in a perfect continuity between logic and mathematics does not appear to increase to any appreciable extent Gone are the heroic days when Russell's aphorism to the effect that "Logic is the youth of Mathematics, and Mathematics is the manhood of Logic" was reverently admitted to be a proved belief The dazzling complexity and austere beauty of the "Principia Mathematica", a perennial masterpiece of which British thought has every right to be proud, caused people to hesitate taking up Russell's challenge "to indicate at what point in the successive definitions and deductions of *Principia Mathematica* they consider that Logic ends and

Mathematics begins". A casual visit to any public or college library would show conclusively that persistent thumb-marks can scarcely be found beyond Part 1 of the first volume of the "Principia": faith leaves the "Prolegomena to Cardinal Arithmetic" and the last two volumes of that monumental work shrouded in their virginal brilliance. What is more, authors of textbooks of logic have asserted that negation and disjunction are the basic operations proposed in the second edition of the "Principia": they had failed to realise that there is an "Introduction to the Second Edition" in which Russell and Whitehead adopt as primitive in the propositional calculus the single notion of 'incompatibility', and direct the reader to replace their original theory of generalised deduction by an important chapter given in an appendix at the end of the volume and based entirely on the stroke notation.

Logicians, however, remembered that authority is not always a sound foundation for argument. With patience and ingenuity, they tried to verify the footsteps of the masters. Soon enough, blemishes which were invisible to the inexperienced were revealed in the structure of "Principia" and diligently discussed by the experts. For example, F. P. Ramsey tried to dispense with the non-formal Axiom of Reducibility by using functions defined in terms of truth-values with a minimum of specific reference to symbols. L. Wittgenstein's criticisms, on the other hand, may have led to some improvements in the exposition of the logistic thesis, but they really constituted a repudiation of its main tenet that logic can be *deduced* from mathematics. L. Chwistek has also tried to bring the unruly Axiom of Reducibility back to the fold, without winning, however, the unreserved approbation of the authors of "Principia". H. M. Sheffer, H. Weyl and J. Nicod, among others, have also suggested improvements; but these can scarcely be taken as adding an ounce of proof to the main contention of the logistic thesis.

(1) A new line of approach is taken by Van Quine in his "System of Logistic" through which he proposes to remedy some technical difficulty of the "Principia". He finds that the system of the "Principia" depends not only on the primitive notions of incompatibility and universal quantification, but also upon a series of operations of predication and abstraction; and furthermore, that the explicit postulates and formal rules of the "Principia" must be supplemented by one series or another of informal rules governing substitution upon function variables. To mend this situation Van Quine proposes a system in which propositions are constructed as sequences of a sort; quantification and the various devices of the propositional calculus are developed in terms of classes, and propositional functions are entirely eliminated from the new system, their duties being taken over by class variables. This clean sweep of one of the major technical complications of the "Principia" is made possible by the adoption of certain new basic notions adequately expressed in an improved symbolism.

The fundamental notion from which the new system starts is that of 'ordination', which includes the traditional subject—predicate doctrine—as one of its particular exemplifications. For example, the proposition predicating whiteness of this paper is simply the sequence (whiteness, this paper), the comma being used as the new symbol for ordination. When propositions are construed as sequences, identity between propositions becomes merely a case of identity between sequences; and these are identical only when their respective affixes are identical and their respective bases are identical.

The two other primitive ideas of the system are 'congeneration', expressed by placing the sign of the operand in square brackets '$[x]$', and 'abstraction' expressed notationally in the form '$\hat{x}\, y$'. The first operation always refers to a class x and indicates that its result is of next higher type than the operand x. The second operation affects a variable x, which is placed under the circumflex, followed by a propositional expression. A set of 'rules of inference', definitions and six postulates helps to manipulate these primitive notions and to derive new theorems. According to this symbolism, for example, the familiar notation of material implication is replaced by $[\hat{x}\ p],\ \hat{y}\ q$, and the definition of number 1 is symbolised as the class of all unit classes of sequences.

The higher generality of this new system is proved by its author through the deducibility of the system of the "Principia". The novelty of the alleged deduction consists less in the reduction of the formal postulates of the system, than in its assimilation of the Axiom of Reducibility as a 'trivial' theorem. This part of the deduction as well as those dealing with descriptions and with unity are probably those which will be submitted to a closer scrutiny prior to their integration into a wider philosophical doctrine involving an appreciation of the relation of the new system of logistic to intuition and to the development of mathematics. At this stage, however, Van Quine wisely avoids discussing the relationship of logic and metaphysics. But if, as Prof. Whitehead says, "Logic prescribes the shapes of metaphysical thought", such a discussion will not be long in taking shape. In the meantime we have little hesitation in sharing the belief expressed in Prof. Whitehead's preface, that Van Quine's book

constitutes a landmark in the history of the subject

(2) Among the many logicians who have devoted their labours to a patient analysis of the "Principia", Max Black has produced an excellent monograph in which he lays bare some fundamental deficiencies of the logistic method, and in which he proposes some suggestions for a reconstruction of the "Principia". He objects to the logistic definition of natural number, shows that Dedekind's definition of a real number is based on intuition, and denies that the logistic treatment of infinity and the continuum clarifies these notions. The difficulties begin with the calculus of propositional functions, interpreted in extension, where many more primitive notions are actually used than are enumerated in the "Principia" The derivation of mathematical functions from propositional functions and descriptions involving the use of 'incomplete symbols' is not at all satisfactory circularity and inconsistency lurk in the background, while the definition of identity, the true nature of incomplete symbols, the status of classes and the intuitions implied in the notions of infinity and continuity, involve non-formal elements which should not be integrated in a rigidly deductive system All these points are forcibly brought home, though Max Black's discussions are often sketchy, and fundamental criticisms are indicated rather than developed

The line of reconstruction suggested by Max Black is based on the necessity of working out an intensional interpretation of propositional functions, and on the initial distinction between the philosophic and the systematic aspects of the logistic system Its technical achievements can be saved by an elaborate reconstruction of its symbolism, by an analysis of the conditions of its significance or by sacrificing its original ambitions After all, similarities between logic and mathematics spring from the fact that logic, in its philosophical aspect, is the syntax of possible states of affairs, while mathematics is the syntax of all organised systems. The relation between mathematics and logic is therefore neither identity nor that of conclusions to premises This view, on the other hand, is strengthened by the pronouncements of the formalist and the intuitionist schools of thought, of which Max Black gives a short but excellent exposition

(3) If the Russellian tradition of logic thus fails to give a formal account of mathematics, so does also the idealistic logic, of which C R Morris supplies a critical survey of its development from Kant to Bradley The two types of logic are widely different: the first claims to be independent of psychology and metaphysics and to restrict its inquiry to the study of the possible inferential relations between propositions, while the second tries to bind thought with experience and to give thus an ordered and necessary account of reality as a whole Roughly speaking, the latter tradition seems to have a wider following at Oxford, while the former has Cambridge for its stronghold They both set out in their course with the conviction that Aristotelian logic is inadequate and that empirical psychology cannot produce an adequate theory of thinking Their reasons for this conviction are, however, different, and while the main grudge of symbolic logic against Aristotelianism is that its analysis of the various forms of propositions and deductions is too restricted and incomplete, the indictment of idealism against traditional logic is that it fails on the whole to explain modern science

Idealistic logic holds that thinking is a discursive operation, so that a judgment is never final, since it is always modified and corrected by a developing system of judgments. Thinking is, moreover, qualified by the mind, which is spontaneously creating a systematic unity. Consequently, C R Morris is at great pains to show that idealistic logic does determine *a priori* the character of experience through an analysis of the forms of thought Yet it is difficult to see how he can claim for it any other result than a legitimate defence of science and the possibility of knowledge against scepticism In particular, if he can show that all statements in the empirical sciences are perfectible by the developing system of judgments, he does not prove that this is also the case for mathematics In other words, the absoluteness of mathematical propositions cannot be explained by the general method of idealistic logic involving an interconnected series of progressive levels of reality, as they cannot be reduced to corrigible judgments The best argument C R. Morris finds, though fully aware of its limitations, in favour of an idealistic account of mathematics is as follows In other spheres thought proceeds by producing systems, certainly in mathematics the statements are the work of an active function of the mind, we may take it that it is the essence of thinking to be systematic here also, a mind which is elsewhere active in the acquisition of knowledge can scarcely, here and there in the course of its experience, be wholly passive, at least in the gaining of knowledge

This, however, is only a pious hope; for we are still left with the unexplained difficulty that in mathematics the actual system-building itself seems to be without empirical taint, while elsewhere it is not C. R. Morris thinks that idealistic logic came to gloss over this difficulty largely because of its emphasis on instances taken from

physics which, owing to its overwhelming use of mathematics, is a misleading case He has to confess also that the special nature of mathematical reasoning has to be left reluctantly as an outstanding, unsolved difficulty We believe, nevertheless, that it is in the light of higher principles and beliefs that mathematics finds its value and ultimate purpose THOMAS GREENWOOD

The Natural Sugars

The Carbohydrates By Dr E F Armstrong and K F Armstrong (Monographs on Biochemistry) Fifth edition Pp vii+252 (London, New York and Toronto Longmans, Green and Co, Ltd, 1934) 15s. net

WITH the publication of the volume under review, the revision of "The Simple Carbohydrates and the Glucosides" is completed In the present fifth edition of this well-known work, the original material has been divided into two volumes, one of which, "The Glycosides", was published in 1931 and reviewed in these columns in that same year More fundamental aspects of sugar chemistry are now dealt with in "The Carbohydrates" In the preparation of both parts of this edition, Dr. E F Armstrong has had the collaboration of his son—Mr K F Armstrong—whose recent lamentable death in the Tyrol has cut short a career of great promise We take here this opportunity of offering to his distinguished father and grandfather an all too inadequate expression of our deepest sympathy

"The Carbohydrates" deals only with the natural sugars and their derivatives; but even with this restriction the field is obviously a wide one, even when, as the authors state in their preface, "we have . restricted as much as possible the discussion of intricate structural problems" The reviewer is possibly unduly attracted by these same structural problems, and possibly it is this that leads him to regret somewhat the absence of a fuller historical account of the development of the important structural conceptions introduced by the first-suggested pyranose (amylene-oxidic) structures advanced in 1923 for xylose and galactose. In view, too, of the prominent part played by the open-chain aldehyde formula in the earlier developments of carbohydrate structure, some more extensive data might have been included concerning the authentic pentamethyl aldehydic hexoses and similar compounds now known These may, however, be judged minor points Within the 250 pages of "The Carbohydrates" and within the limits already mentioned, there is presented a very well-balanced survey of the present position of the sugar group

During the decade which has elapsed since the appearance of the fourth edition the advances then foreshadowed have become co-ordinated, and the appearance of the new edition is well-timed Obviously much had to be omitted and the authors have selected well, and in the wide field afforded by the sugars selection is not an easy matter To quote again the authors' preface, "the sugars have attracted workers of every nationality Emil Fischer would have been well pleased to see that there had been no loss of interest in his favourite theme and satisfied that his own work has stood the test of time" The extensive developments of Fischer's work which have resulted from this international activity may readily be appreciated by comparing the chapter headings of the present edition with those of previous editions of the same work—expansion of old fields and the development of entirely new ones are there very well shown

"The Carbohydrates" as a whole will be of great interest and service alike to the sugar specialist and to workers in other fields The biochemist will probably find the last two chapters especially interesting These cover the relation between configuration and biological behaviour, and the problem of the synthesis of carbohydrates in the plant

Quantum Mechanics

Elementary Quantum Mechanics By Dr R W Gurney Pp vi+160 (Cambridge At the University Press, 1934) 8s 6d. net.

THERE is now a number of volumes of an introductory character on the new quantum theory, and in reading them one is struck by the diversity in the methods adopted for introducing the beginner to this subject Some begin with matrix analysis, some with generalised dynamics and others mingle philosophy with physics This diversity is largely due to the fact that there is, as yet, no accepted formal method of approach, nor has it been decided what previous knowledge is to be assumed on the part of the student of the new developments The particular method of teaching the subject will vary according to whether stress is to be laid upon its mathematical or experimental aspect. It would appear that many physicists regard the subject as almost exclusively suited to those with a considerable degree of mathematical training and ability. They will be agreeably surprised to find from this volume that it can be easily studied from the experimental physicist's point of view.

The old quantum theory of the atom began with a study of the properties of the Rutherford model, the new theory begins with the study of the atom as a region of variation of potential The book under notice illustrates the new methods by means of some simple problems and their appropriate energy diagrams The reader is bound to be familiar with these illustrative examples, and he will find that the new problems appear in a garb which is no more unfamiliar than an old friend in a new suit The author's method may well be adopted as the method of choice for beginning this subject, especially for those whose interest lies chiefly in experimental physics

In expanding the subject and in introducing the wave equation, a number of special problems is considered. Some of these are common to most books of this character, such as the problem of the hydrogen atom and of electron spin Others are less familiar and make an appeal to chemists as well as to physicists, such as the subjects of valence bonds and molecular formation A chapter is devoted to electrons in crystals and insulators and conductors

It is not too much to say that of all the good elementary books on the subject, this volume brings out most successfully and simply the physical aspect of the recent theory.

Short Notices

From Galileo to Cosmic Rays a New Look at Physics By Prof H B Lemon Pp xviii+450 (Chicago University of Chicago Press, London Cambridge University Press, 1934) 17*s* 6*d* net

THE problem of telling, in simple fashion, something of the fundamental principles of physical science—the ordinary workaday notions which serve to help us in our dealings with a macroscopic world—as well as something of yesterday's sensational developments, is an important and urgent matter, but one of supreme difficulty

What are we to do in order to cater for, not only that exacting fellow, the intelligent layman, but also the undergraduate who is destined to go out in natural science, in the classics, maybe even with that *ægrotat* in botany which was the fate of the Rev. Lancelot Ludovic Soulsby ? He has enough and to spare of expanding and of island universes, he can talk glibly of the principle of indeterminacy Is it possible, in a short, systematic course, to provide him with the essential background, and to give him some intelligent grasp of, say, the law of the conservation of momentum, the measurement of horse-power, the kinetic theory of heat, an explanation of thunderstorms, the propagation of waves, and so to lead him to the story of the nuclear atom, and atomic transmutation ?

Prof. Lemon has made a gallant attempt to achieve the almost impossible, and, in so doing, has pressed into his service most of the devices known to modern pedagogy. a liveliness of exposition that does not degenerate into cheapness, a most unorthodox use of the pictorial art, a number of very fascinating stereoscopic photographs; and an enthusiasm for his subject that never fails him

The result is an arresting volume, in one respect, the book reminds one of the original edition of Maxwell's "Matter and Motion"—it is only the professional who can realise the immense amount of labour which must have gone to its production It makes pleasant and easy reading, which, a *bouleversement* of an almost proverbial saying, affords some measure of the author's industry. A. F.

Board of Education Educational Pamphlets, No 101 · *Senior School Mathematics* Pp 67 (London H M Stationery Office, 1934) 1*s*. net

THE recent reorganisation of the elementary schools of Great Britain has naturally led to the establishment of a large number of 'senior schools' of various types The Board of Education has therefore published this pamphlet in order to give some guidance to teachers in laying out adequate courses in mathematics adapted to the varying needs of such schools.

After an interesting introduction, there follow ten well written chapters on the scope of the work likely to be of the greatest use to the pupils. Freed from examination preparation and purely formal study, the exploration of a suitable course becomes a very thought-provoking task It will be evident that a senior school will need more especially a practical bias, and in mathematics, this means not only arithmetic of everyday life, but also considerable amount of actual practical work, such as mechanical drawing, simple surveying and the like All these problems are adequately discussed from many points of view, and some excellent suggestions are made. The final two chapters are particularly helpful, for they deal with the difficult and thorny problems of the special course for girls and the treatment of the backward pupil

Progressive teachers of mathematics will be in thorough agreement with the suggestion concerning the unity of the several branches, arithmetic, algebra and geometry, given in par. 26, but it is doubtful whether that measure of agreement will be afforded to the suggestion of par. 72 There seems no valid reason for suppressing the y in plotting a simple algebraic function; indeed, the complete equation $y = f(x)$ leads to a more intelligent grasp of the graphical representation and the relation between variables.

The whole pamphlet, nevertheless, is an inspiring contribution to a difficult problem, and teachers generally will welcome the many excellent suggestions made therein F. G. W. B.

Radio Receiver Measurements By Roy M Barnard Pp xii+116 (London: Iliffe and Sons, Ltd, n.d.) 4s 6d. net

THIS "concise handbook for the radio service engineer" is a happy augury for the day when radio service will be done by engineers and not by 'black-coat' plumbers The author is chief inspector of broadcast receivers to a large manufacturing concern, and the quality of the book, within the limits which the author imposes on himself, is sufficiently guaranteed by this fact The limits are much narrower than the title suggests; tests made on the 1931 schedule, on which the work is based, will fail to give a really adequate representation of receiver performance The book would, from this point of view, be disappointing and dangerous were it addressed to the testing staff of the manufacturer But since it is, in fact, addressed to the men who must deal with the set after it has left the factory, the book may be very cordially commended. An urgently needed rise in the standard of radio service work would result from its general circulation, but it is doubtful whether any very large proportion of those now offering themselves as radio service engineers are fitted to benefit by the author's guidance

It is gratifying to learn that the manufacturing side of the industry is taking steps to improve the situation in this respect When they have done this, the manufacturers will perhaps find time to turn their eyes back to their own test and inspection departments, which are, in many cases, quite unworthy of their producing departments Too frequently the inspection department allows the set to reach the customer with faults of a much simpler, but no less annoying, nature than those discussed by Mr Barnard

Tiefseebuch ein Querschnitt durch die neuere Tiefseeforschung In Beiträgen von C W Correns, A. Defant, F Goszner, W Stahlberg, O v Schubert, H. Wattenberg, G Wüst (Das Meer in volkstümlichen Darstellungen, Band 3) Herausgegeben vom Institut für Meereskunde zu Berlin unter Schriftleitung von Georg Wüst. Pp. vi+144+16 plates. (Berlin E S Mittler und Sohn, 1934) 4 80 gold marks

THIS is a compilation showing the present position of research particularly in respect to the deeper waters of the ocean It is excellently put together, well illustrated and commendably brief It is divided into as many sections as there are authors, and it advertises the very honourable part that Germany has taken in marine exploration Route sheets of eight German expeditions are reproduced. Of these expeditions, that of the *Meteor* of 1925-27 will be of most interest to readers, since its scientific results are not as yet generally known, and the present work is largely written by its scientific staff The *Meteor's* topographical work and that of the *John Murray* expedition, both based on sonic sounding, give a completely new conception of the bottom topography of the oceans Furthermore, there were new methods and aims, here summarised, in all parts of the work of this expedition, chemical, physical and biological Many selected sections and charts are given and those of the South Atlantic merit most careful study We require to settle many problems now by intensive work, especially topographical, physical and chemical, in the Pacific, where questions of circulation, temperature, salinity, etc, are simplified by its open character and great size This will be clear to all who are interested enough to study this excellent little book

The Structure of Spectral Terms By Prof W M Hicks Pp xi+209 (London Methuen and Co, Ltd, 1935) 10s 6d net

THE present volume, intended as a supplement to the author's "Analysis of Spectra" which appeared in 1922, sets out at length the results of his investigations during the last twenty five years The object of the work—in which Hicks stood alone—is to obtain empirical relations between spectroscopic data and various physical properties of the elements

As the title suggests, the writer was concerned only with the term values derived from analysis of the observational data, so the first chapter is appropriately devoted to the different formulæ that may be used to represent term series Useful numerical examples indicate the methods used in practice to adjust the values of the constants in the formula and to evaluate the Rydberg constant

The next seven chapters present a detailed account of the author's attempts to deduce atomic constants from his own interpretation of line spectra Satelloids, the 'oun', high order emission, linkages, summation lines, *s*-, *p*-, *d* and *f*-terms are successively treated, the text being supplemented by numerical tables to illustrate the points under discussion Finally, the theory of atomic structure is reviewed in relation to the whole of the foregoing results

Rydberg's term symbols are retained, although they seem to offer no advantages over the usual modern notation, and the text is marred by excessive use of abbreviations E G J

The Testing of Bituminous Mixtures a Laboratory Handbook concerning Road and Building Materials By Donald C Broome, with a Chapter on Roofing Felts, by R O Child. (The Roadmakers' Library, Vol 2) Pp vii+194 (London Edward Arnold and Co, 1934) 15s net

THE art of road-making is rapidly becoming transformed into a science, which possesses a "Road makers' Library" of its own The bituminous binding materials are now used after study of their chemical and physical characteristics instead of being applied haphazard, a number of the tests have been standardised The English literature on the subject is scanty, and there is need for a book which brings the existing knowledge together The two sections deal respectively with the testing of the constituent materials and of the finished mixture, and there are the usual appendixes containing tables The work is written primarily for those actually engaged in this class of work and should prove of value

The Negative Proton

By Dr G. Gamow

Alice laughed "There's no use trying," she said: "one *can't* believe impossible things" "I daresay you haven't had much practice," said the Queen. "When I was your age I always did it for half an hour a day. Why, sometimes I've believed as many as six impossible things before breakfast"

"Through the Looking Glass"
LEWIS CARROLL

DURING the last few years, physical knowledge has been considerably enriched by the discovery of several new kinds of particles Besides the old-fashioned protons and electrons, *neutrons, positive electrons* and hypothetical *neutrinos* came on to the stage of the physical world However, the discovery of new particles did not make our picture of the physical world more complicated, but on the contrary led to simplification and added to the symmetry of this picture, in fact, the existence of such particles was expected from general theoretical considerations long before their discovery We must notice particularly that the discovery of positive electrons removed the principal problem of the dissymmetry of electric charge, and at the present time the predomination of negative electrons in our observations is just a matter of the part of the universe in which we are living However, this question is still outstanding in connexion with heavier particles, and the only way to remove completely the existing asymmetry in the electric charge would be to introduce the notion of *negative protons* and to prove their existence

It might seem at first sight that the negative protons could be introduced in the same way as positive electrons in Dirac's theory, that is, by considering them as holes in the continuous distribution of protons corresponding to negative energy-levels However, this extension of Dirac's hole theory for protons can be justified only if the Dirac relativistic wave-equations are applicable to these particles, which does not seem to be true In fact, the analysis of the foundations of Dirac's theory given by Bohr has shown that this theory may be applied to a particle only under the condition that *the radius of the particle is small compared with the critical length*. $l = h/mc$ (where m is the mass of the particle in question)

For an electron, we have

$$l_e = \frac{6 \cdot 5 \times 10^{-27}}{0 \cdot 9 \times 10^{-27} \times 3 \times 10^{+10}} = 2 \cdot 4 \times 10^{-10} \text{ cm.}$$

which is much larger than the radius of the electron estimated from its mass according to the classical relation $r_e = e^2/mc^2$ ($= 3 \times 10^{-13}$ cm). Even if we do not believe in this formula, based on the hypothesis of pure electromagnetic mass for the electron, we can be quite sure that the electron is not so large as 2×10^{-10} cm, because otherwise the finite radius of the electron would be noticeable for the electronic orbits of heavier atoms which have radii of the same order of magnitude. Thus for electrons, the conditions for validity of Dirac's theory are fulfilled and it can be successfully applied with all its consequences

The situation is rather different for a proton, as here the critical length becomes

$$l_p = \frac{6 \cdot 5 \times 10^{-27}}{1 \cdot 7 \times 10^{-24} \times 3 \times 10^{+10}} = 1 \cdot 4 \times 10^{-13} \text{ cm}$$

Although the direct observations of anomalous scattering of fast protons in hydrogen which would give us the value for the radius of proton have not yet been made*, we have still much evidence that the real radius of the proton is not much smaller than l_p and most probably of the same order of magnitude. General considerations concerning the nuclear model constructed from protons and neutrons show that the stability of such a model can only be secured if we accept the strong repulsion between constituent particles at small distances, which is equivalent to the introduction of 'rigid radii' of the order of magnitude $1 \cdot 3 \times 10^{-13}$ cm The same value can be obtained from the experiments on scattering of neutrons in hydrogen One can say, of course, that applying to a proton the same classical mass-radius relation as for an electron, we shall have a much smaller value for the radius ($= 2 \times 10^{-16}$ cm), but the applicability of this relation is based on the hypothesis of pure electromagnetic mass of a proton, which does not seem to be correct for heavy particles; applying the same relation to a neutron, we should have for it the radius zero, which is definitely wrong *Thus it is not to be expected that a proton can be described by Dirac's equations*, and there are no reasons to expect that the consequences of those equations also should hold for a proton. First of all, as indicated by Bohr, the magnetic moment of the proton need not necessarily be given by Dirac's relation $\mu = eh/4\pi cm$, and in fact it was shown by the experiments of Stern and Frisch that this moment *is about two and a half times larger* There is also no justification for speaking of the negative proton level-distribution, of the holes in

* Experiments on the scattering of fast protons in hydrogen have been carried out by Wills (Johns Hopkins dissertation, 1934), but the number of observed collisions was not enough to support any conclusions about deviations from Rutherford's scattering formula.

such a distribution, or of the existence and annihilation of negative protons in the sense of Dirac's theory.

We can ask, of course, what equations must be applied to describe the relativistic quantum motion of a proton. So far, Dirac's equations have been shown to be the only wave-equations mathematically possible which are consistent with the theory of relativity. The most plausible way out from this paradoxical situation would be perhaps to say that we do not need any relativistic quantum equations for a heavy particle in such a case. In fact, we shall need such equations for a proton only in extremely strong fields (not existing even inside nuclei) and it is very probable that under such violent external forces the transformations of a proton into a neutron and vice versa, with the creation of positive and negative electrons ($p \to n + \overset{+}{\beta}$, $n \to p + \bar{\beta}$), will happen so often that there will be no longer any physical meaning in speaking about *one particle*. However, even for strong intranuclear fields, the velocities of protons and neutrons are still small compared with the velocity of light, and in these cases the ordinary Schrodinger equations can be applied. It may be that just the fact that the ratio (velocity of nuclear particle/velocity of light) is not exactly zero is responsible for the neutron-proton transformations in the nuclei, for the description of which we must have an as yet unknown theory for the *behaviour* (*motion and transformations*) of heavy particles.

The considerations given above show us that, in introducing negative protons for the sake of considerations of general symmetry, we must not be guided at all by the analogy with the theory of positive electrons. We must choose the properties of this new particle in the way most consistent with the observed symmetry of the physical world. It seems, therefore, most natural to consider the negative proton as symmetrical with the positive proton in respect to a neutron. From this point of view, the mass and the absolute value of charge for a negative proton must be exactly equal to those for a positive one. As already mentioned above, no such process as annihilation must be expected for two kinds of protons, but for the sake of symmetry we have to accept for the negative proton the possibility of transformation into a neutron and vice versa, with the emission of an electron. Thus we obtain the following general scheme of transformations for heavy particles:

$$\bar{P} \underset{\overset{+}{\beta}}{\overset{\bar{\beta}}{\rightleftarrows}} n \underset{\overset{+}{\beta}}{\overset{\bar{\beta}}{\rightleftarrows}} \overset{+}{P}.$$

We see that for nuclei containing also negative protons the processes of negative- or positive-electron emission can both happen in two different ways; this can be of great use for the explanation of the two different types of β-decay of the same nucleus which are observed, for example, for uranium-X_1 (see later).

The forces between negative protons and other particles can also be obtained to a large extent from symmetry considerations: the interaction between a negative proton and a neutron must be identical with the interaction between a positive proton and neutron as suggested by Heisenberg (a strong attraction, rapidly decreasing with distance, changing to a strong repulsion at very small distances) and the interaction between two negative protons must be mainly due to Coulomb forces. Symmetry considerations cannot, however, give us any idea of the forces between a negative and a positive proton; in order to estimate these, we must consider the general stability conditions of an atomic nucleus. One can show that in order to explain the existence of positively charged stable nuclei, it is necessary to introduce *a rather strong repulsion between two kinds of protons.* In fact, if there were no such repulsion, the most stable state of the nucleus of a given total number of particles of atomic weight A (the state with maximum binding energy) should correspond to $A/2$ neutrons, $A/4$ positive protons and $A/4$ negative protons, because in this case we have the maximum number of neutron-proton-bindings and minimum of repulsive Coulomb forces. Since for real nuclei the most stable state does not correspond to zero charge, we must introduce forces preventing the formation of equal number of positive and negative protons in the nucleus, which can only be done if we accept a very strong repulsion between the two kinds of protons at nuclear distances. Such forces will reduce considerably the number of protons of one kind in any given nucleus, and will permit none or perhaps just one negative proton in the light nuclei and more in heavier ones. Of course, from this point of view, we should expect the existence of negative nuclei with positive electrons circulating around them in some part of our universe.

We come now to an interesting question about the magnetic moments of heavy particles. The symmetry considerations force us to ascribe to a negative proton the magnetic moment of the same absolute value but of opposite sign to that of a positive proton. We must also expect that *the magnetic moment of a neutron is exactly zero*. This seems, however, to cause serious difficulties in understanding the small value of the magnetic moment of a deuton, which according to Stern and Esterman is only about 0·7 nuclear magnetons. In his attempt to explain the observed momenta of

atomic nuclei, Schuler argues in the following way. Accepting the spins of neutron and proton as each equal to $\frac{1}{2}$, and supposing that those two particles move in the deuton on the fundamental S-level with the orbital momentum $j = 0$, we must conclude that both spins are parallel in order to explain the observed spin of the deuton, which is equal to 1. Since the magnetic moment of a proton is about 2·5 nuclear magnetons (Stern and Frisch) and the magnetic moment of the deuton only about 0·7 (Stern and Esterman)*, we must conclude that the magnetic moment of the neutron is equal to $0{\cdot}7 - 2{\cdot}5 = -1{\cdot}8$ nuclear magnetons and is directed oppositely to the spin.

One can, however, show that these conclusions are not necessarily unique, and that it is possible to explain the observed values for the deuton while still accepting a magnetic moment of the neutron equal to zero and compensating the magnetic moment of a proton by its orbital magnetic moment. In fact, accepting the fundamental level of two particles in the deuton as a D-level with orbital angular momentum $j = 2$, we can explain the observed spin of this nucleus by supposing that the spins of proton and neutron are both parallel and opposite to the orbital momentum $(2 - \frac{1}{2} - \frac{1}{2} = 1)$. Of course, one can argue against the D-level hypothesis by saying that there is a theorem of wave-mechanics according to which the fundamental state of a system of two particles interacting with central forces is always an S-state. However, it is very doubtful whether this theorem can be applied to our case for, as we have seen, the radii of the two particles in question are of the same order of magnitude as the distance between them in the deuton nucleus. Putting the matter pictorially, one may say that the radius of the S-orbit for a neutron and a proton may be smaller than the sum of the radii of two particles, so that this orbit is excluded by geometrical considerations. In more technical terms, that would mean that *the laws of ordinary wave-mechanics are no longer applicable in detail when the heavy particles more or less penetrate into each other's structure*, which seems to be quite rational if we remember what was said before in this connexion.

It may seem at first that the introduction of a D-orbit would immediately give us two units of magnetic moment to compensate the large moment of the proton. This is not so, however, for since one of the particles is neutral, the total orbital momentum $j = 2$ will give rise only to one unit of magnetic moment. Here again the finite size of the proton comes in to help us. We have seen that for the rotation of a proton around its axis, the *gyromagnetic ratio* is about five times larger than for the rotation of a proton around a distant axis: in the first case we have:

$$\frac{\text{magnetic moment}}{\text{mechanical momentum}} = \frac{2{\cdot}5}{\frac{1}{2}} = 5,$$

and in the second

$$\frac{\text{magnetic moment}}{\text{mechanical momentum}} = \frac{1}{1} = 1.$$

The fact that this ratio for the proper rotations of a proton is equal to 5 and not to 2, as required by Dirac's theory, was accounted for by the finite size of a proton, and will be explained only when we know the distribution of charge and mass in this particle. *In any event, we must expect that if the proton is rotating around an axis at a distance comparable with its own radius (which is usually the case in the nuclei) the gyromagnetic ratio for orbital motion must not be expected to be unity but may be considerably larger*: this effect can increase the orbital magnetic moment of a proton in the deuton nucleus to a large extent and make the total magnetic moment of the deuton sufficiently small. It should be noticed, of course, that the above considerations do not pretend to give any explanation of the observed magnetic moments of nuclei, but just show that one must be very careful when drawing definite conclusions in this region before the theory of heavy particles is really constructed.

One of the most interesting applications of negative protons to the theory of nuclear structure is the possibility of the existence of nuclei with equal atomic numbers and equal atomic weight but still possessing different structure and different properties. Such *isomeric nuclei* can be obtained if we replace a pair of nuclear neutrons by one positive and one negative proton. Two such nuclei evidently possess the same mass and charge, but may have different spins and different binding-energies (mass-defects). One of such isomeric nuclei possessing larger energy will usually be unstable and subject to transformation into the other isomer by the simultaneous internal transformation of two particles

$$\begin{matrix}\overset{+}{p} \to n \\ \overset{-}{p} \to n\end{matrix} \quad \text{or} \quad \begin{matrix} n \to \overset{+}{p} \\ n \to \overset{-}{p}\end{matrix},$$

however, the probability of such double transformations (just as in the case of double α- or β-emission) is extremely small and we should expect such isomeric nuclei to be metastable. Thus the isomeric nucleus will differ widely from an ordinary excited state of a nucleus, for which the emission of surplus energy in the form of a γ-quantum usually takes place in a very small fraction of a second ($\sim 10^{-14}$ sec.).

* Both values with considerable probable error.

We can give an example in which the notion of isomeric nuclei may be of great use In the region of the heavy elements there exist the stable isotope of lead $_{82}\mathrm{Pb}^{210}$ found by Aston* which is isomeric with β-decaying RaD, and the isomeric nuclei UX_2 and UZ resulting by β-forking from UX_1 and both giving after the emission of a second β-particle the nucleus of U_{II} In the last case, two different β-branches leading from UX_1 to U_{II} $UX_1 \xrightarrow{\bar{\beta}} UX_2 \xrightarrow{\bar{\beta}} U_{II}$ and $UX_1 \xrightarrow{\bar{\beta}} UZ \xrightarrow{\bar{\beta}} U_{II}$ may be considered as due to the above mentioned two possibilities for $\bar{\beta}$-emission $n\bar{p} \xrightarrow{\bar{\beta}+} pp \xrightarrow{\bar{\beta}+} pn$ and $np \xrightarrow{\bar{\beta}} nn \xrightarrow{\bar{\beta}+} pn$ giving rise to isomeric nuclei at the half-way stage

* The existence of this isotope is unfortunately not quite definitely proved

It is interesting to notice here that the negative protons are the only particles, apart from neutrons, for which there are no potential barriers around the nuclei, and therefore one would expect that substitutional reactions of the type

$$_{n}X^{m} + {}_{0}n^{1} \rightarrow {}_{n+1}Y^{m} + {}_{-1}p^{1}$$

would be probable even for the heaviest elements It is not impossible that some of the Fermi reactions for heavy elements may be explained on this basis

In conclusion, we may say that there are so many indications of the existence of negative protons that the hope is justified that these as yet hypothetical particles, completing the symmetry of the physical world, will be found sooner or later.

Progress in Medical Research*

THE report of the Medical Research Council for 1933–34 reveals the wide boundaries within which investigations relating to health and disease are being initiated and supported throughout Great Britain, and reflects the rapid development of medical science as well as the need for scientific knowledge as a guide in practical affairs Parliament provided a grant-in-aid of £139,000 for the Council's expenditure during the present financial year, the provisional allocation of which is, for administration £9,000, for the expenses of the National Institute for Medical Research including the farm laboratories £54,000 and for research grants to scientific workers and for the investigations of the Industrial Health Research Board £76,000 The funds available have, as usual, been augmented from other sources for the promotion of particular schemes of research

Lord D'Abernon resigned his membership of the Council, the vacancy was filled by the appointment of the Marquess of Linlithgow, who was also elected chairman of the Council in succession to Lord D'Abernon. Prof. E Mellanby also resigned his membership on being appointed secretary of the Council, Prof H. S Raper was appointed to succeed him. Sir Charles Sherrington and Dr J A Arkwright retired and Prof A J. Clark and Prof J C G Ledingham were appointed members It was decided that the tribute to the late Sir Walter Morley Fletcher, for which funds had been collected during the year, should consist in the first place of a personal memorial, in the form of a portrait bust to be placed in a suitable setting in the National Institute for Medical Research, and secondly of the inception of some scheme for the advancement of knowledge for the relief of human suffering, which, it is proposed, should be the foundation of a Walter Fletcher Laboratory at Mill Hill, to be devoted particularly to nutritional studies

The Department of Biological Standards at the National Institute now holds twenty-three different standards Thirty-three different countries, including British Dominions, have been supplied with samples of some of them during the year The standards for gas gangrene antitoxin, staphylococcus antitoxin and two anti-pneumococcus sera, prepared at the Institute, have now been adopted by the Permanent Commission on Biological Standardisation of the League of Nations, and units defined in terms of them They will be preserved at the State Serum Institute, Copenhagen, for international distribution The work carried out on vitamin standards by and for the Accessory Food Factors Committee was reported to the second International Conference on Vitamin Standards held in London last June the National Institute continues to hold the four standards for vitamins A, B_1, C and D and is responsible for their international distribution

In the field of clinical research the Council has applied the funds released by the permanent endowment by the Rockefeller Foundation of the post held by Sir Thomas Lewis at University College Hospital, to the establishment of a new Clinical Research Unit at Guy's Hospital, Dr R T. Grant has been appointed director The opportunities for clinical research are steadily widening The report refers to the departments established during the past few years, including

* Committee of the Privy Council for Medical Research· Report of the Medical Research Council for the Year 1933–34 (Cmd 4796) Pp 172. (London H M. Stationery Office, 1935) 3s net

those at the National Hospital for Nervous Diseases, Queen Square, at King's College Hospital, at the Middlesex Hospital and finally at the new British Postgraduate Medical School, for which funds have been supplied by various benefactors or responsible authorities

The work on viruses at the National Institute has been actively continued. The important discovery by Laidlaw, Andrewes and Wilson Smith that the virus of human influenza can be transferred to ferrets, mentioned in last year's report, has opened up a new line of attack on the problems of this disease It has now been found that mice can be infected from ferrets by suitable methods, for example, intranasal inoculation under light ether anæsthesia The animals show signs of illness of a pneumonic type, which is usually fatal The disease can be transmitted from mouse to mouse and from mouse back again to ferret the direct infection of mouse from man has not yet been attempted, in the absence of an epidemic of influenza. The virus has been detected in the throat washings of only one case of illness, clinically diagnosed as 'influenza', out of a number examined The method of transmission to the mice is of crucial importance, and there is no evidence of a natural spread of the disease from infected animals to others living with them Neutralising sera can be obtained from the ferret, horse and pig after infection with the virus, and the blood serum of practically all human subjects recently examined contains such a neutralising antibody The infection for the mouse can be neutralised by ferret serum and the animal afterwards rendered hyper-immune by repeated administration of the virus The influenza virus is very similar to that found by American workers in 'hog influenza', which causes a severe illness in the ferret or mouse · the original disease in swine, however, is caused only by the joint action of the virus and a visible bacterium

Sir Henry Dale, working with Drs. Gaddum, Feldberg and Vartiainen, has continued his experiments on the nature of the process by which nervous impulses are transmitted from the nerve endings to the cells under their control It is highly probable that the effectiveness of practically all messages passing from the central nervous system to voluntary muscles and other organs of the body depends upon the liberation, at particular points of their course, of acetylcholine In the case of the sympathetic nervous system, however, the substance liberated at most nerve endings is related to adrenaline. An exception is the nerve-supply to the sweat glands, which, although belonging to the sympathetic system, yet, in the cat at any rate, acts by the liberation of acetylcholine. Sir Henry Dale has used the words 'cholinergic' and 'adrenergic' for nerve fibres the effects of which are transmitted by acetylcholine and a substance related to adrenaline respectively It now appears that the preganglionic fibres of the whole autonomic system and the motor fibres to striated skeletal muscle are cholinergic, together with the postganglionic fibres of the parasympathetic division of the autonomic system, the postganglionic fibres of the sympathetic system are predominantly, but not exclusively, adrenergic These observations throw light on the experiments of Langley and Anderson thirty years ago on the replacement of the fibres of one nerve by those of another in regeneration They showed that voluntary motor fibres and preganglionic fibres of any part of the autonomic system could functionally replace one another, or postganglionic fibres of the parasympathetic system, but not postganglionic fibres of the sympathetic system These observations can now be summarised by saying that cholinergic fibres are interchangeable with other cholinergic fibres, and adrenergic with other adrenergic fibres, but that fibres employing different methods of chemical transmission cannot replace one another.

Another type of evidence showing the importance of specific chemical substances in the working of the nervous system has been brought to light by nutritional experiments, for example, the work of Peters on the rôle of vitamin B_1 in the oxidation of carbohydrate in the brain and of Mellanby on the degenerative changes occurring in nerve cells and their conducting fibres when the supply of vitamin A or carotene in the diet is insufficient. The fibres and cells chiefly affected are the afferent, and their degeneration is followed, or accompanied by, changes in the epithelial surfaces connected with them, resulting in microbial infection It appears that nerve cells may play a much larger part in aiding the defence of certain tissues against infection than had previously been suspected.

Among the many other investigations carried out by, and for, the Council, that on 'accident proneness' has a special interest at the present time. Recent work has widened the field of inquiry from that of ordinary industrial risks, to include the study of road accidents With regard to the former, it is now well established that certain persons have a special liability to be the subjects of accidents; for example, 10 per cent of a group may be responsible for 75 per cent of the accidents occurring amongst them. The phenomenon is independent of any question of responsibility or blameworthiness. It has been found that those who sustain an undue number of one kind of accident also sustain an undue number of other kinds, and that accident proneness is a relatively

stable quality, so that if those who have an undue number of accidents in their first year of exposure are eliminated, the subsequent accident ratio of the group is diminished A similar relationship has been found to hold for motor accidents The elimination (on paper) of those who sustain an undue number of accidents in an initial period of exposure reduces the accident rate shown by the remainder of the group in the subsequent period The report suggests that data are already available, in the records of the insurance companies, for giving a trial to this method of accident prevention on a large scale. The novelty of the method, as compared with judicial disqualification, lies in the facts that it makes use of information provided by minor accidents and that it is dissociated from any question of blame, since a man cannot be blamed because his reactions are slower than those of others Yet it appears reasonable that he should be removed from a position in which he is a danger to himself and others, or by appropriate tests be prevented from reaching this position.

Obituary

SIR JAMES WALKER, F.R.S

THE death of Sir James Walker at Edinburgh on May 6, in his seventy-third year, severs one of the last links between classical and modern physical chemistry Closely connected in work and friendship with the three great founders of the science on the Continent—van't Hoff, Ostwald and Arrhenius—Walker may be justly regarded, indeed, as the protagonist of physical chemistry in Great Britain during the last forty years. His text-book, "Introduction to Physical Chemistry", has passed through ten editions since its first appearance in 1899, and has probably assisted more students towards an easy, yet serious, appreciation of the science than any other single volume. Several of the more significant chapters of the subject—for example, those on hydrolysis and amphoteric electrolytes—were largely his own original work Walker was also, however, a skilled organic chemist, and his success in attacking purely technical problems was exceptional In an age of increasing specialisation, he retained to the last an unusually wide range of interests, and kept himself up to date in a great many diverse fields. Remembering the bitter controversies in which he participated as a young man, while the revolutionary ideas regarding the nature of solutions were being forced upon his reluctant seniors, he was always particularly open-minded in his attitude towards the work of the second generation of physical chemists which has recently effected another revolution in this same field He recognised quite complacently that, if they could see farther than Arrhenius, it was, after all, only because they were standing on Arrhenius's shoulders.

Born in Dundee in 1863, and educated at Dundee High School, Walker entered the University of Edinburgh in 1882 and was inspired by Crum Brown to seek an academic career in chemistry After obtaining the degree of D.Sc for his thesis on "The Dehydration of the Metallic Hydroxides by Heat", in 1886 he proceeded to Baeyer's laboratory in Munich to engage in organic research, but at the end of six months, learning that Ostwald had been appointed professor of physical chemistry at Leipzig, he hastened to become the first British pupil of that new school, and graduated therefrom as Ph.D. in 1889 with a thesis on "The Affinity Constants of Organic Bases"

For the next three years, Walker served as research assistant to Crum Brown at Edinburgh, his most outstanding contribution being on the electrolytic synthesis of organic acids. In this period falls also the inauguration of the Alembic Club, an association of assistants in the chemistry department which afterwards undertook the publication of fundamental papers of historical interest—the Alembic Club Reprints—with gratifying success

An introduction to Ramsay at the memorable Leeds meeting of the British Association in 1890, where van't Hoff and Ostwald triumphantly vindicated their views against a mass attack of their opponents, led Walker in 1892 to enter Ramsay's laboratory in University College, London, first as a research worker and later as an assistant In 1894 he was selected to succeed Percy Frankland in the chair of chemistry at University College, Dundee, and for fourteen years he occupied that post in his native town, adding steadily to his reputation for research, teaching and administrative ability. He was elected a fellow of the Royal Society in 1900, and when his old teacher, Crum Brown, resigned in 1908, Walker was appointed to fill the vacancy at Edinburgh.

Here Walker found that his first and most urgent duty was the reorganisation of the laboratories, which had become entirely inadequate. The solution of this problem was delayed until after the War, but the new Department of Chemistry at King's Buildings, completed in 1924 and still unrivalled in Great Britain, constitutes a fitting memorial to his twenty years occupancy of the Edinburgh chair During the War he rendered valuable services to the country by erecting and equipping, in conjunction with some of his colleagues in the Department, a factory for the manufacture of T.N T which produced as much as fifty tons of the explosive weekly. The efficiency of the plant may be illustrated by the statement of the Department of Explosives Supply that its figures for nitrogen economy during the months of September and October, 1918, constituted a record for the country.

In 1921 Walker received a knighthood and was also elected to the presidency of the Chemical Society.

His expert advice was sought by many committees—such as the Fuel Research Board, the Advisory Council for Scientific and Industrial Research, the University Grants Committee, and the Carnegie Trust—to all of which he gave generous and conscientious service. He was awarded the Davy Medal of the Royal Society in 1926. The Royal Society of Edinburgh honoured him at the beginning of his career with the Makdougall-Brisbane Medal in 1895, and at its close with the Gunning Victoria Jubilee Prize in 1933. He was an LL.D. of the Universities of St. Andrews and Edinburgh.

Although he retired from the Edinburgh chair of chemistry in 1928, Sir James Walker maintained for several years an active interest in his old department, visiting it almost daily and participating in a most stimulating manner in its various research activities. His many friends hoped that this Indian summer of his life-time would prove of long duration, but it was not to be. As his body weakened, his visits became regretfully rarer, but the spirit of James Walker was going strong to the very end.

Walker was a man of singular simplicity and charm, working unselfishly always for his department and for his profession. He possessed a remarkable gift for languages (for years he abstracted Russian papers for the *Journal of the Chemical Society*) and an intense love of music. He is survived by his wife, the daughter of Lieut.-Colonel W. Sedgwick of Godalming, whom he met as a research student at University College, and by a son, Dr. Frederick Walker, now lecturer in geology in the University of St. Andrews. His scientific progony, however, including not only those who have studied directly under him but also those who have been inspired by his writings, are legion. Wherever physical chemistry is mentioned among English-speaking chemists, the first name that springs to mind is that of Sir James Walker.

JAMES KENDALL.

WE regret to announce the following deaths:

Dr. Charles E. St. John, research associate at the Mount Wilson Observatory, Pasadena, and associate of the Royal Astronomical Society, on April 26, aged seventy-eight years.

Prof. Hugo de Vries, For. Mem. R.S., emeritus professor of botany in the University of Amsterdam, on May 20, aged eighty-seven years.

News and Views

Sir Robert Muir, F.R.S.

BY common consent, Sir Robert Muir, professor of pathology in the University of Glasgow, is the leader of British pathology, as was shown by the enthusiasm with which his colleagues gathered together last year to testify to their respect and affection for him and to celebrate his seventieth birthday. The recent award to him of the Lister Medal is a proper recognition of the value of his work to surgeons as well as pathologists. This Medal is awarded triennially, irrespective of nationality, for distinguished contributions to surgical science; it consists of a bronze medal and a sum of £500. Sir Robert is an old-fashioned all-round pathologist, morbid anatomist and bacteriologist, and his own researches have covered a wide field—anæmia, immunity, tumours, iron metabolism, etc. He has illuminated any subject to which he has been drawn to pay attention, and his comprehensive knowledge has been spread beyond his immediate pupils by two popular textbooks on pathology and bacteriology, the latter originally written in partnership with his friend James Ritchie, and by the number of his pupils who hold chairs and other positions of distinction in pathology in Britain and the Dominions, where they no doubt reproduce some of his teaching though they can scarcely duplicate his personality.

Prof. P. Zeeman, For.Mem.R.S.

PROF. PIETER ZEEMAN is seventy years of age on May 25 and in consequence retires from the professorship of physics and directorship of the Physical Institute of the University of Amsterdam. In order to allow his many admirers an opportunity of showing their appreciation of his important contributions to science, it is proposed that a jubilee volume be published, to which thirty distinguished physicists have already promised contributions, and that a Zeeman fund, a Zeeman medal or some similar method of encouraging research be founded. A general committee with representatives from all parts of the world has been formed with an executive committee under Prof. J. D. van der Waals, Jr., with T. L. de Bruin, of 33 Gerard Terborgstraat, Amsterdam S. as secretary and treasurer to carry out the proposals, and an appeal is now made for funds in support of the scheme. Pieter Zeeman was born in Zeeland at the mouth of the Schele and was educated at the University of Leyden. In 1890, when twenty-five years of age, he was appointed assistant on the physics staff, and held the post of *privatdozent* when six years afterwards he detected the effect of a magnetic field on the light sent out by a source placed in the field, each line of the normal spectrum being split up into a number of components each polarised and in general displaced. Prof. Lorentz based his explanation on the motion of electrons in the field, but this has been replaced by the quantum theory of the permitted energy of the emitter, which explains the anomalous, as well as the normal, effect. Zeeman was appointed professor of physics in the University of Amsterdam in 1900, was Nobel laureate in physics in 1902, was elected a foreign member of the Royal Society in 1921 and awarded the Rumford Medal of the Society in 1922. The most important of Zeeman's later work was concerned with the convection of light by moving liquids and solids. He found that its magnitude depends on the dispersion

of the medium as well as its refractive index, in agreement with the theory of Lorentz rather than with the older one of Fizeau

Dr. A. C. Haddon

CONGRATULATIONS are due to Dr. A. C. Haddon, of Christ's College, Cambridge, and formerly reader in ethnology in the University, on the attainment, on May 24, of the age of eighty years. Apart from his personal qualities, of which this is not the place to speak, Dr. Haddon's lifelong and unselfish devotion to scientific research have won him the admiration and respect of a wide circle; while his originality of thought and his scientific achievement hold a commanding position in anthropological studies, which has stood unchallenged for more than a generation. When in the course of his first visit to the Torres Straits he turned from zoology to the study of the native peoples, the technique of ethnological investigation in the field was in its infancy. The great expedition to the Torres Straits, which he organised later, in the closing years of the nineteenth century, under the auspices of the University of Cambridge, has been an inspiration and a model for all the more important of the expeditions of ethnological investigation which have followed.

THE Torres Straits expedition served also as a training school, for of those who accompanied Dr. Haddon, the late Dr. W. H. R. Rivers and Prof. C. G. Seligman in their turn became great teachers, and in the field and the lecture-room developed and passed on his methods and ideals to generations of students. Dr. Haddon's insistence on the importance of field-work has become a fundamental principle in modern ethnological training; and his stress on its urgency has ensured many a record of custom and institution which otherwise might have been lost owing to rapid change among the backward peoples. His efforts in promoting the training in anthropology of officials and missionaries have been no less beneficial to science than to the Empire, and in the organisation of anthropological studies in Great Britain his influence has long been profound and far-reaching. We wish him still some years in which to enjoy the fruits of his labours in contemplating the continued advance of anthropological science.

Centenary of the Royal Observatory of Belgium

THE Royal Observatory at Uccle has just celebrated its first centenary by a number of official functions. At the opening ceremony, which was graced by the presence of His Majesty the King of Belgium, addresses were read on the history of the Observatory by the director, M. Paul Stroobant, and on Adolphe Quetelet the founder of the Observatory by M. Demoulin, president of the Observatory Council. Receptions were given at the Hotel de Ville by Burgomaster Max and at the Fondation Universitaire. But the event of chief scientific interest was the visit to the Observatory itself, when the Minister of Education inaugurated a number of new instruments obtained with the aid of a generous Government grant. Amongst these mention must be made of an Askania meridian circle, a Zeiss double astrograph, a 1-metre Zeiss reflector and a number of auxiliary pieces of apparatus. The meridian circle is provided with a number of electrical devices and gives a photographic record of the reading circles for each observation; it can be reversed in 30 seconds. The Zeiss double astrograph is of focal length 2 m., working at $f/5$; the object glasses are quadruplets designed by Sonnefeld. The Zeiss reflector works at $f/3$ at the Newtonian focus for direct photography, but it is hoped later to add a Ross correcting lens. A 2-prism spectrograph is provided for use with the telescope as a Cassegrain reflector at $f/10$. The whole of the recently acquired equipment, on which the Observatory and its director are to be congratulated, is described in full detail in the *Bull. ast. de l'Obs. roy. de Belgique*, 2, 1935. The British delegates attending the centenary were Dr. L. J. Comrie, director of the Nautical Almanac, Mr. J. H. Reynolds, president of the Royal Astronomical Society, and Prof. F. J. M. Stratton, general secretary of the International Astronomical Union.

Search for Oil in Great Britain

THE danger of dependency on foreign supplies of liquid fuel and the necessity of finding alternative domestic resources are now openly avowed by all thinking people. There are some who fervently believe that there is sufficient petroleum below the ground in England to supply the entire demand for petrol and oil for an indefinite period, and are prepared to back their opinions financially, in spite of adverse geological opinion (NATURE, March 31, 1934, p. 487). The regulations prepared by the Mines Department of the Board of Trade under the Petroleum Production Act constitute an official invitation to those people to prove their theory. At the same time they safeguard the interests of the State in the event of a systematic search for oil proving successful, and ensure that development of any resources found will be conducted in an orderly manner. The essential facts are that if no negative resolution is passed by either House within the twenty-eight Parliamentary days, both prospecting and mining licences will be issued under these regulations. Applicants for such licences must furnish evidence of their technical and financial qualifications and then on payment of the requisite fee, £20 for a prospecting licence or £50 for a mining licence, will be entitled to a monopoly of the area covered. The prospecting licence is tenable for three years and may be renewed for two further yearly periods; the mining licence for fifty years with the possible extension for a further twenty-five years. Prospecting licences will be granted in respect of areas not exceeding 200 square miles or less than 8 square miles, and mining licences in respect of areas neither larger than 100 square miles nor smaller than 4 square miles. The rate of royalty payable to the State has not yet been fixed but it will not be less than 3*s.* nor greater than 6*s.* per ton of crude oil. For any 'casinghead' spirit recovered, the royalty imposed will be not less than one-eighth of a penny or more than 2*d.* per gallon.

Afforestation and Scenery in Great Britain

DURING the past few months, a number of letters and articles have appeared in the Press and in journals regarding the damaging effects of afforestation on the landscape of Britain. In some cases, the Forestry Commissioners have, rightly or wrongly, come in for adverse criticism on the ground of having desecrated some of England's beauty spots, notably in the Lake District, by planting serried ranks of conifers. We may assume that even the Forestry Commissioners have souls, and that they are not wholly devoid of the aesthetic sense, but they have a duty to perform to the nation, that of providing an adequate reserve of standing timber, and however great may be their desire to avoid any action which might seriously affect the beauty of the countryside, they cannot be expected to be entirely impartial judges in matters affecting their programme of work Here there is more than one interest involved, and in cases where interests conflict, the wise thing is for the parties concerned to meet and come to a friendly agreement We therefore welcome the announcement that the Forestry Commissioners and the Council for the Preservation of Rural England have set up a joint informal committee, which will meet from time to time and endeavour to come to an agreement in cases where their respective interests are likely to clash It is hoped that this will be the means of maintaining the beauty of the country without seriously affecting the important work being carried out by the Forestry Commission

Holly Lodge Farm

AT a meeting on May 16 of the Select Committee of the House of Commons on Unopposed Bills, the Metropolitan Water Board Bill was considered. Under this Bill, it is sought to construct various new works, including a reservoir covering 417 acres in the Staines area and another about 374 acres in extent in the Walton and Weybridge area This latter will involve submerging Mr F W Secrett's Holly Lodge Farm (see NATURE, February 2, p 177, and February 9, p. 228) On behalf of the Metropolitan Water Board it was stated that the farm has been brought to a very high state of cultivation, chiefly by the use of artificial manures, and also due to the fact that the soil is of a certain consistency. It is not contended that there is no other soil in the country of the same physical consistency, or which could not be brought finally to an equal state of high cultivation Indeed, if there were not, then this farm of 180 acres could not be considered to be of the slightest use to the nation The arrangement is that the lessee of the farm shall remain in possession for at least two years, in order that, if he thinks fit to do so, he will have time to change to another farm on which he may carry on his very useful work. The Committee found the preamble of the Bill proved, and it was ordered to be reported for third reading.

The Green Flash

SINCE the appearance in NATURE of May 4 of the letter by Prof. Worley, with a brief comment by Lord Rayleigh, on this subject, further correspondence has been received confirming the suggestion that "the green flash is by no means a rare phenomenon" Mr. H Cary Gilson, Trinity College, Cambridge, states that he has observed the flash several times during the past five years from a point in Sussex 150 ft above sea-level In October 1933, while in the Gulf of Aden with the John Murray Expedition, "the flash could be clearly seen, with or without glasses, almost any evening", and was even observed from a port-hole about 18 in above the water. Mr Northcote Thomas, Grove Cottage, West Malvern, Worcs, has sent a summary of observations made from the upper part of West Malvern, 800 ft above sea-level He states that a flash or similar phenomenon was seen on forty-one occasions between July 25, 1934, and April 20, 1935. The flash was green until about mid-September; blue or green from September 17 until October 8; blue from October 11 onwards On occasions the colour persisted for half a minute Previous volumes of NATURE will show that the green flash has already received considerable attention, and index entries to letters on the subject will be found in vols. 93–95, 110, 111, 120–123 The comparative frequency of the occurrence and the change of colour to blue were referred to, and also its appearance at sunrise as well as sunset The weight of evidence, and particularly the sunrise effect, points to a physical explanation of the phenomenon, which is accepted by Prof R W Wood in a letter in NATURE of March 31, 1928 (p 501), where he suggests that the relative temperature of the atmosphere and the surface with which it is in contact is the determining factor; a cold surface with warm atmosphere would increase the normal gradient of refractive index, and also the curvature of the rays, so delaying 'sunset' and affording "greater opportunity for atmospheric dispersion to come into play"

Memorial to the late Dr. W. C. Unwin

BY the older engineers of the present day, the late Prof W. C Unwin will be remembered as an outstanding figure in the fields of engineering education and the practical application of scientific principles to the needs of civil and mechanical engineers. In his long career, which covered the latter half of the last century and the first quarter of the present, he witnessed the greater part of the evolution of engineering as we know it to-day, and in all the branches of the profession with which he was more directly concerned he occupied a pre-eminent position. He died on March 17, 1933, aged ninety-four years; an appreciation of his life and work appeared in NATURE of May 13, 1933 (p. 681). A representative committee, under the chairmanship of Sir Alfred Chatterton, of Unwin's friends and old students, supported by representatives of the Royal Society, the principal British and American engineering societies and of the educational organisations with which he was connected, has now been formed for the purpose of establishing a suitable memorial. The committee is endeavouring to raise funds for the founding of an Unwin scholarship at the City and

Guilds (Engineering) College, of which Unwin was the first professor of civil and mechanical engineering and the first dean, and to publish a biographical memoir based upon the one which was published in the Unwin Memorial issue of the *Central*, the journal of the City and Guilds College Old Students' Association, and so make available a record which so far has only been published for private circulation Fuller particulars of the Committee's proposal can be obtained from the joint honorary secretaries, Messrs. G. A Hicks and J Severs, c/o The Institution of Civil Engineers, Great George Street, S W.1, and contributions to the fund should be sent to the honorary treasurer, Mr. E G. Walker, 82 Victoria Street, London, S W 1

Communications and the Manufacturer

THE fourth of the "Green Papers" issued by the Post Office contains a lecture by E S Byng to the P O Telephone and Telegraph Society read on January 15, 1934 He points out that the outstanding success of telephone development in the United States is attributed in some measure to the close working arrangement between the operating and manufacturing departments of the business. In the Bell system, the various operating companies and manufacturing associations are controlled by the American Telegraph and Telephone Co In Great Britain, the State, as owner of the whole system, does not attempt to manufacture to any appreciable extent The production of the necessary materials and plant is rightly entrusted to industrial companies By mutual co-operation and understanding, the Post Office and the manufacturers should be able to operate in much the same way as a single organisation. Of recent years, after work has been begun on a contract, engineers rarely ask for changes to be incorporated Inspection in a factory may be likened to a running commentary on manufacture, as the inspection includes observing, reporting and criticising. It varies from so little as 2 per cent to 100 per cent of the total goods manufactured. Some processes call for continual vigilance, while others have mechanical safeguards against inaccurate performance. The telephone dial alone consists of nearly seventy 'piece' parts each of which must be checked for accuracy of forming and its dimensions gauged between the maximum and minimum limits. In succeeding stages, the tensions of the springs are measured, the dimensions to the thousandths of an inch and the speed of operation to thousandths of a second

A New Domestic Coke

A REPORT issued by the Department of Scientific and Industrial Research (H M. Stationery Office, 9*d.* net) records a test by the Director of Fuel Research on a plant erected by the British Coal Distillation Co., Ltd., at Newbold, Leics., and designed to prepare a smokeless fuel from an entirely non-coking coal, high in ash. The unwashed coal is first dried and passed through a revolving inclined retort, where it is carbonised at 600° C. by hot products of combustion of producer gas. The residue from the retort is discharged into a trough of water, and the 'clean' coke, which floats, is skimmed off the surface, while the dirt sinks and after removal is used for fuel on the plant. The resultant 'clean' coke is made with pitch into briquettes, which are stored to give a domestic fuel. The throughput of the plant as claimed—100 tons per day—was substantially confirmed, giving a fuel which was considered satisfactory for the open grate, a notable achievement for such a raw material This is a technical test made in accordance with the normal practice of the Department, and does not purport to give an opinion about the commercial success of the process

Journal of the Royal Horticultural Society

WITH the publication of vol. 49, Part 3, in September 1934, the *Journal of the Royal Horticultural Society* became a useful and informative monthly publication instead of a quarterly or half-yearly volume The change should be welcome to all concerned, and certainly it will enable the Society to inform members of its activities more efficiently. Lord Aberconway, president of the Society, outlined the main features of the change in the September issue. The *Journal* has maintained a high standard of learning, science and practice for nearly fifty years, and has grown from a tiny circulation to a very large one. The new arrangement is designed "to add rather than to replace. . . . Records will be more up-to-date, news can be given while it is still fresh, information of coming events can be made available; notes of more immediate interest can be introduced; the most recent information as to the Society's activities at Wisley can be included". The "Book of Arrangements" will no longer be issued, but the information will be included in the January and February numbers of the *Journal*. The parts which have appeared since the change was effected show that the standard is even higher, if that is possible, than of old, whilst the total volume of subject-matter seems to have increased.

National Research Council, Canada

THE seventeenth annual report, for 1933–34, of the National Research Council of Canada, in addition to reviewing the researches on analysis and testing conducted in the National Research Laboratories, gives a summary of the activities of associate committees and of assisted researches in university and other laboratories and under scholarships. A financial statement is included, together with particulars of the personnel of the various research, advisory and special committees. Among the researches completed in the National Research Laboratories during the year may be mentioned investigations on the suitability of Canadian clays for oil-refining, the bonding of rubber to metal, the chemical investigation of Canadian weeds poisonous to livestock, the suitability of Canadian wools for the manufacture of cloth, the causes of premature seeding in turnips, the stability of aircraft floats and the correction of instability in aircraft used for photographic survey work. Researches conducted under associate committees have dealt with methods for combating losses due to

animal and plant diseases; the evaluation of insulating materials, the incidence and control of dangerous parasites in the livestock and wild life of Canada; the distribution and eradication of destructive weeds. Increasing use is being made of the research information service, and attention is directed to the desirability of expanding the National Research Library. The report surveys the outlook for the work of the Council, and concludes that every indication points to the more intensive application of science to industry, including agriculture, than in the past. The opportunities in the survey of resources, in standardisation, and particularly in the building industry and the utilisation of agricultural wastes, are stressed.

Institute of Physics

THE annual general meeting of the Institute of Physics was held on May 14 After election of officers and completion of the panel of the Board, it was announced that the following would take office on October 1 *President*, Prof. A Fowler, *Vice-President*, Dr. G W. C Kaye, *Honorary Treasurer*, Major C E S. Phillips; *Honorary Secretary*, Prof J A. Crowther, *New Members of the Board*, Mr. A. P. M Fleming and Dr B L Worsnop The annual report for the year 1934 states that the total membership of the Institute at the end of that year was 753. New activities have included the holding of informal discussions on industrial physics and the completion of the scheme for the training of laboratory assistants and the issuing of certificates of competence in laboratory arts The report shows that employers are making greater use of the services of the panel of consulting physicists and of the appointments register.

International Conference on Documentation

THE thirteenth International Conference of the International Institute of Documentation will be held in Copenhagen on September 9–14, under the presidency of Dr Alingh Prins. The following subjects will be considered. methods of documentation, theory of classification, indexing and abstracting services, co-operation between libraries and abstracting services, statistics, cataloguing, rights of authors in respect to photo-copies, decimal classification and classification of standards and patents, and also classification in municipal administration. Further information can be obtained from Mr E. Lancaster-Jones, Honorary Secretary of the British Society for International Bibliography, Science Library, South Kensington, London, S W.7

Congress of Physical Education

THE Belgian Medical Society of Physical Education and Sport has organised an international congress to be held at Brussels on June 30–July 3, when the following subjects among others will be discussed: motor tests in physical education, introduced by Prof. Laugier (Paris), Covaciu Ulmeanu (Bucharest) and René Ledert (Liège), cycling, introduced by Prof. Hedon (Montpellier), W. Missiuro (Warsaw), Brandt (Geneva) and Prof. C. Heymans (Ghent). The subscription is a hundred Belgian francs. Further information can be obtained from the secretary, M. Rebuffat, 50 rue de l'Abbaye, Brussels.

Conference on Spectroscopy

A THIRD special programme on "Spectroscopy and its Applications" is to be held at the Massachusetts Institute of Technology this summer, culminating in a research conference during the week July 15–20. This conference, which is to be held in the George Eastman Research Laboratories, will comprise lectures and discussions on photographic photometry, absorption spectrophotometry, spectroscopic analysis of materials, biological and chemical effects of spectral radiation, spectroscopy of the extreme ultra-violet, and astronomical applications of spectroscopy The meetings of the first day will be largely devoted to consideration of general spectroscopic problems of the metallurgist, chemist and biologist; on July 16 and 17 the chief emphasis will be on specific applications of spectroscopy to biology and medicine. During the latter part of the week, applications of spectroscopy to astronomy will be emphasised, a portion of the programme being held in collaboration with the Harvard Observatory Summer School The research conference coincides with the conclusion of the Institute summer school courses in practical spectroscopy, and the meetings are open to all interested persons An invitation is being extended by the Institute to all properly qualified investigators, to make use of the facilities of the spectroscopy laboratory in connexion with their researches during such portions of the summer months as they may desire. A bulletin giving further information regarding the entire summer programme on spectroscopy can be obtained from Prof. G. R Harrison, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts

Institution of Electrical Engineers Awards

THE following awards of premiums for papers read during the session 1934–35, or accepted for publication, have been made by the Institution of Electrical Engineers: Institution premium to N. Ashbridge, H. Bishop and B. N MacLarty; Ayrton premium to R Grierson and D Betts; Fahie premium to W. West and D. McMillan; John Hopkinson premium to W. D. Horsley, Kelvin premium to C. E. Webb and L. H Ford; Paris Exhibition (1881) premium to A. Monkhouse; Overseas premium to F. T. M. Kissel; extra premiums to Dr. T. E. Allibone, W. G. Hawley and F. R. Perry; C. Wallace Saunders, H. W. Wilson and Dr. R. G. Jakeman, E. S. Byng, C. M. Longfield; R Poole; Dr. J. C Prescott and Dr. J. E. Richardson. *Wireless Section Premiums:* Duddell premium to C F. Booth and E. J. C. Dixon; extra premiums to R H. Barfield and C. R. Burch and Dr. C. Sykes *Meter and Instrument Section Premiums:* Silvanus Thompson premium to Dr. N. H Searby; extra premium to Prof. J. T. MacGregor-Morris and J. A. Henley. *Transmission Section Premiums:* Sebastian de Ferranti premium to Dr. D. M. Robinson; extra premium to W. J. John and F. M Sayers.

Announcements

A DISCUSSION on "Supraconductivity and other Low Temperature Phenomena" will be held by the Royal Society on Thursday, May 30, at 11–1 and 2 30–4 The discussion will be opened by Prof J C McLennan. It is hoped that the following will be present and that many of them will speak Prof N Bohr (Copenhagen), Dr R De Laer Kronig (Groningen), Prof L Brillouin (Paris), Dr W Meissner (Berlin), Prof W H Keesom (Leyden), Prof W J De Haas (Leyden), Prof F Simon, Dr K Mendelssohn, Dr H London, Mr J D Bernal, Dr J. D. Cockcroft, Dr L C Jackson, Dr R Peierls There will be an open discussion during the afternoon.

DR WILLIAM E GYE, of the National Institute for Medical Research, Hampstead, has been appointed to succeed Dr. J. A. Murray as director of the Imperial Cancer Research Fund on the latter's retirement at the end of this year Dr Gye, whose publications on cancer are well known, was formerly a member of the staff of the Imperial Cancer Research Fund.

THE Fuel Research Station, East Greenwich, of the Department of Scientific and Industrial Research, will be open for the annual visitation on June 4 at 2–6 p m.

THE new solar telescope provided for Prof H H Plaskett at the University Observatory, Oxford, is to be formally opened on June 11 by the Vice-Chancellor After this ceremony, an address on "The Physics of the Sun" will be given by Sir Arthur Eddington.

THE seventh annual Haldane Memorial Lecture at Birkbeck College, London, E C 4, will be delivered by Mr C E M Joad, head of the Department of Philosophy at the College, on Wednesday, May 29, at 6 p m Mr. Joad will take as his subject "Science and Human Freedom" Admission is free, without ticket

THE trustees of the Rockefeller Foundation have promised £60,000 towards the cost of the building and equipment of the proposed Institute for the Teaching and Study of Neurology at the National Hospital for Nervous Diseases, Queen Square, Bloomsbury, London, W C 1, and a further sum of £60,000 towards the endowment for teaching and research which will have their centre in the new building.

THE admirers, friends and pupils of the late Dr. Émile Roux, director of the Institut Pasteur in Paris, have decided to establish a national fund to be known as the Roux Foundation to pay the expenses of young students of biology The general secretaries are M Sieur, Inspector-General of the French Army, and Prof Marchoux, member of the Academy of Medicine. Subscriptions should be sent to the treasurer, M. Dufaure, 205 rue de Vaugirard, Paris.

THE *Journal of South African Botany*, a new quarterly periodical, published under the authority of the Trustees of the National Botanic Gardens of South Africa and edited by R. H Compton, is designed to provide a medium for the publication of research work on the South African flora The first part (issued in January 1935) contains a systematic and historic account of the genus *Freesia* by the late N E Brown Nineteen species are described W. F Barker, T M Salter and R H Compton contribute a paper dealing with new African plants in which eight species of *Erica* and two of *Hessea* are described and illustrated

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —An assistant lecturer and demonstrator in botany and one in comparative anatomy and zoology in the University College of South Wales and Monmouthshire, Cardiff—The Registrar (May 30). An assistant lecturer in metallurgy in the County Technical College, Wednesbury—The Director of Education, County Education Offices, Stafford (May 30) A University reader in statistics at University College, London—The Academic Registrar, University of London, S.W 7 (May 31) A lecturer in electrical engineering in the Walsall Technical College —The Director of Education, Education Office, Council House, Walsall (June 1) An assistant experimental officer (physics or electrical engineering), a technical assistant (physics and electrical engineering), and an experimental assistant at the War Department Establishment, Biggin Hill, Kent—The Superintendent (June 4) A secretary of the Royal Commission on Ancient and Historical Monuments (Scotland)—The Secretary, 27 York Place, Edinburgh, 1 (June 5). An assistant lecturer in organic chemistry at King's College, London—The Secretary (June 6). A lecturer in mechanical engineering in the Cannock Chase Mining College—The Director of Education, County Education Offices, Stafford (June 6) An assistant lecturer in geography in University College, Nottingham—The Registrar (June 6) An acting director of research to the British Launderers' Research Association—The Secretary, B L.R.A, 17, Lancaster Gate, W.2 (June 8). A professor of mining in the University College of South Wales and Monmouthshire, Cardiff—The Registrar (June 15). An assistant advisory officer in fruit growing to the Kent Education Committee—The Agricultural Adviser, Springfield, Maidstone (June 15) Two assistants (III) at the Royal Aircraft Establishment, South Farnborough (physics or engineering)—The Chief Superintendent A head of the Mechanical and Civil Engineering Department, Battersea Polytechnic, S W.11—The Principal A deputy mechanical engineer in the Egyptian State Railways Administration—The Chief Inspecting Engineer, Egyptian Government, 41 Tothill Street, S.W.1 An assistant in the Mineral Resources Department of the Imperial Institute, South Kensington, S W 7—The Secretary.

Letters to the Editor

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P 879

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

Density of Light Water: Ratio of Deuterium to Hydrogen in Rain-Water

WE have prepared light water by electrolysing natural water and burning the gases evolved The water so produced was about 100 parts in 10^7 lower in density than the natural water, on re-electrolysing this, its density was further reduced by about 14 parts in 10^7, and a third stage in the process reduced the density still further by 12 parts in 10^7 We have experimental evidence that the third stage light water is almost free from deuterium oxide, which is confirmed by a calculation of the separation obtainable under the actual conditions of the experiment These observations give, then, a difference in density at 27° C. between the third stage water and rain-water (oxidised to remove organic impurity and twice distilled) of 127 in 10^7, and imply that there is one volume (or molecule) of deuterium oxide to 8500 volumes (molecules) of hydrogen oxide in rain-water E H. and C K Ingold, H Whitaker and R Whytlaw-Gray[1] found 1 in 9000 for this ratio, and Urey[2], 1 in 5000 We find the ratio cannot readily be determined with precision because of the difficulty of purifying natural water without changing its density

In the relative density measurements, the temperature was observed at which a small fused silica float (completely immersed in the water) was in equilibrium, neither rising nor falling Platinum thermometry was used, and the average error of a determination was about 2 in 10^7, but for the light water the density during a number of distillations remained constant to 1 in 10^7. In this respect it proved strikingly different from natural water, which diminished in density each time it was distilled. When a sample of tap water was fractionally distilled, the difference in density between the first and last fractions was 200 in 10^7, showing that deuterium and hydrogen oxides can be separated by distillation and pointing to the interesting conclusion that, if precise relative determinations of the density of water which had been repeatedly distilled had been made at any time since accurate thermometry has been available, they would have disclosed the fact that natural water is not a simple substance.

A Sensitive Polarographic Test for the Absence of Rhenium in Manganous Salts

IN 1925, the present author jointly with V. Dolejšek[1] reported on the occurrence of element No. 75 (Mendělěev's dwimanganese) in manganese salts However, the discoverers of rhenium, I. and W. Noddack[2], and others[3] expressed doubts as to whether any measurable traces of this new element could occur in manganese specimens I investigated the polarographic behaviour of potassium perrhenate and found that it is deposited at the dropping mercury cathode at the potential $-1\cdot2$ v from the normal calomel zero (Fig 1 Curve 2) This method is sensitive enough to show the presence of perrhenate when its concentration is 10^{-6} m in 1 m. $MnCl_2$,[4] or in alkaline solutions, even if they contain tungstates or molybdates in considerable amounts

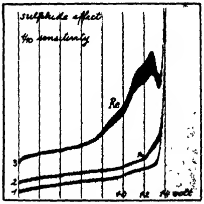

FIG 1 Polarographic curves for 1 m manganese chloride (Kahlbaum) (1) pure, (2) with 10^{-5} molar potassium perrhenate, (3) repeated after treatment with hydrogen sulphide

As the polarographic 'step' at $-1\cdot2$ v. is not conclusive for the presence of rhenium, so long as other elements are present which are electro-deposited at about that potential (for example, cobalt, iron, nickel, zinc), these were removed from the manganese salts by hydrogen sulphide in the presence of sodium acetate and acetic acid Some perrhenate was purposely added, which in this way could not be precipitated but merely converted into Re_2S_7 or thioperrhenate[5] Curiously enough, after this treatment an abnormal increase and shift of the perrhenate 'step' ensued (Curve 3), which was especially marked when the acidic reserve of the buffer had been enlarged by increasing the concentration of the acetate and acetic acid. Thus the perrhenate is easily detectable in a 10^{-6} m. solution; as 0·1 c.c. of the solution suffices for polarographic analysis, detection of 2×10^{-8} gm. (0·02 γ) is possible. In the absence of perrhenate, no such effect is observable, even when traces of copper, lead, cadmium, zinc, nickel, cobalt, iron, molybdate and tungstate are present. Although it is not yet ascertained that the described abnormal polarographic effect is specific for perrhenate, its lack can be taken as proof of the absence of rhenium in specimens.

Several specimens of commercial manganese salts were thus investigated polarographically as to their

content of traces of rhenium. In all cases the rhenium effect was lacking, proving that commercial manganous salts contain certainly less than 1 part of rhenium per 1,000,000 of manganese, so that the steps at −1·0 v. and −1·2 v shown on polarograms of *manganous solutions* (Curve 1), as well as the lines of the X-ray spectrum[1], must have been due to coinciding effects of other elements than 75

The large current, provoked by the presence of perrhenate in the buffer solution, is probably due to the deposition of hydrogen, catalysed by a sulphide compound of rhenium[6]

Biological Synthesis of Ascorbic Acid

IN a previous letter[1] we pointed out that the liver tissues of the rat, rabbit and pigeon are able to synthesise ascorbic acid from mannose *in vitro*, while those of the guinea pig and monkey are unable to do so Further experiments indicate that this power is not common to all animals independent of an external supply of ascorbic acid. The liver tissues of the ox, cat and fowl, for example, cannot convert mannose into ascorbic acid *in vitro*. This might mean either that some other organs in their body are able to effect this transformation or that some entirely different means (for example, bacterial) is employed in these animals for the synthesis of the vitamin

The *in vitro* experiments with rat tissues have now been confirmed by experiments *in vivo* It has been found that the intravenous injection of mannose (20 mgm.) into rats is followed by a rise in the ascorbic acid content of the tissues investigated, the animals being killed 5 hours after injection Similar injections of glucose (20 mgm.) also increase the ascorbic acid content of the adrenal gland, though less strikingly, as shown by the average figures given in the following table Subcutaneous injection of mannose (20 mgm) daily for three successive days also leads to a similar rise in the ascorbic acid content of the tissues.

Nature of experiment	Ascorbic acid (mgm) formed per gm of tissue			
	Adrenal	Small intestine	Kidney	Liver
Controls	2 53	0 26	0 17	0 18
Mannose (intravenous)	4 83	0 30	0 21	0 22
Glucose (intravenous)	3 75	0 25	0 17	0 18

Another point of interest to which we wish to refer is that in preliminary experiments we have found

Nature of tissue	Ascorbic acid (mgm) formed per gm tissue
Guinea pig embryo	0 14
Ovary of the pregnant guinea pig	0 05
Ovary of the adult non-pregnant monkey	0·30

that embryonic guinea pig tissue at an early stage of development, ovarian tissue of the pregnant guinea pig and ovarian tissue of the adult non-pregnant monkey are also capable of converting mannose into ascorbic acid *in vitro* on incubation for 5 hours at *p*H 7·4 in a mixture of phosphate buffer and Ringer-Locke solution at 37° This is shown in the accompanying table

The guinea pig embryo has been found to lose this power of converting mannose into ascorbic acid gradually with its development In these experiments carried out under the stated conditions, the replacement of mannose by glucose does not lead to an appreciable synthesis of ascorbic acid

The above observations (especially those with the intravenous injection of glucose) indicate that while glucose is the ultimate precursor of ascorbic acid, it has probably to pass through the intermediary stage of mannose or some mannose-like configuration

The experiments with the ovarian tissue of the monkey appear to have implications concerning the human species, while those with the guinea pig embryo seem to be interesting from the point of view of the theory of recapitulation

Estimation of Ascorbic Acid by Titration

IN the course of an investigation of the ascorbic acid content of raw and cooked Ontario foodstuffs, employing a modification of the titration procedure outlined by Birch, Harris and Ray[1], we observed that, in the case of cauliflower, carrots, parsnips, beets and potatoes, the titration value was higher in the cooked than in the raw food This was reported in October 1934 at a meeting of the Toronto Biochemical Society[2] Ahmad[3] has recently reported an increase in the case of cabbage, which we found to give only a decrease after heating for short periods

We have made determinations at regular intervals when two of the above vegetables were heated under constant conditions The increase in titration value against phenolindophenol is very rapid at first, reaching a maximum within five minutes in most cases if oxidation is retarded by the addition of cyanide, or by heating in an atmosphere of nitrogen or carbon dioxide. If oxidation is not inhibited there is not so great an increase in titration value Following the increase there is a gradual decline as heating is continued In the case of Ontario cauliflower, the increase is 60 per cent of the value of the raw vegetable.

It is unlikely that this increase is due to cellular disintegration as a result of heating, and consequently more thorough extraction of ascorbic acid. We were at first impressed with the likelihood of the increase being caused by the liberation of a sulphhydryl compound. However, this explanation was shown to be erroneous since colorimetric tests for cystine and cysteine are almost negative in these cooked vegetables. The character of the curves secured by plotting titration values against time of heating is such that we believe the increase is due to the setting free of bound ascorbic acid, perhaps from an ester.

In the case of certain plant tissues, then, a simple extraction and titration procedure does not give the

complete value for ascorbic acid, but only measures the free acid This amount is augmented by hydrolysis caused by heating There may be present, also, an amount of reversibly oxidised ascorbic acid which is not measured by titration, unless it is first reduced by hydrogen sulphide, an observation recorded by Tillmans[4] and others. Ascorbic acid in all these forms may be biologically active, but only one can be estimated by simple titration Unlike these plant tissues, bovine adrenal tissue contains little bound ascorbic acid and none of the reversibly oxidised compound Acid fruits, such as lemons, oranges and tomatoes, resemble adrenal tissue, in containing only free ascorbic acid

Extreme Infra-Red Investigation of Hindered Rotation in Water

STRONG evidence for a quasi crystalline structure in liquids has been furnished by X-ray analysis, the splitting of monochromatic light into a triplet by scattering, specific heat considerations, Raman effect[1] and by an interpretation of viscosity[2] Recently Debye[3] has succeeded in explaining several additional phenomena by assuming that not only do the molecules in a liquid vibrate under the influence of an intermolecular field about a centre of gravity which is slowly changing in space, but also that their free rotation is hindered From two independent analyses, Debye concludes that in liquid water a rotation of the dipole moment through 90° would produce a potential energy of about $10kT$

The extreme infra-red spectrum of water vapour is composed of a multitude of lines extending beyond 500μ which correspond to the combination of pure rotational frequencies about the principal axes, having for moments of inertia[4] 0 995, 1·908 and $2{\cdot}980 \times 10^{-40}$. The absorption of liquid water has been measured[5] at 108μ and 313μ and led to the verification of Debye's dispersion formula for polar molecules In Fig 1 are shown the percentage of transmission and reflection of water between 52μ and 313μ (the filled circles refer to measurements made by Rubens[6]) From these data the absorption coefficient and index of refraction were calculated. The increasing values for the absorption coefficient and index of refraction from 90μ to 313μ are in agreement with the theory of dipole moments, however, an anomalously high absorption occurs below 90μ[6]. Considering the index of refraction to be continuously rising, in agreement with the simple dipole theory, this absorption produces an anomalous dispersion between 70μ and 90μ, and is not due to internal vibrations of the water molecule (which are well known and are in the near infra-red), or to pure rotation bands (which have been measured in the vapour state throughout this region). This absorption has the appearance of a fundamental frequency and, following a suggestion of Prof. Debye's, might be due to a hindered rotation of the molecules.

Assuming the oscillations to be small and nearly harmonic, their frequency is given by $\nu = \frac{1}{2\pi}\sqrt{\frac{K}{I}}$, where K is the torsional constant and I the moment of inertia Taking ν as 140 cm^{-1} (which, as might be expected, is not clearly defined) and considering rotation about the axis having a moment of inertia of $2\ 980 \times 10^{-40}$ (which would be infra-red active), the torsional constant opposing free rotation amounts to $5kT$ A frequency of 140 cm.$^{-1}$ corresponds to an energy of $0\ 7kT$, so there should be several quantum states for this hindered rotation. If we adopt the above value for the restoring torque, a hindered rotation about the axis having a moment of inertia of $0{\cdot}998 \times 10^{-40}$ (which would also be infra-red active) would have its fundamental frequency at 240 cm^{-1} or 42μ This frequency lies close to the first overtone of the oscillation about the axis of greatest moment of inertia, so that especially strong absorption is expected near 40μ, but our apparatus was not suitable for measuring below 52μ.

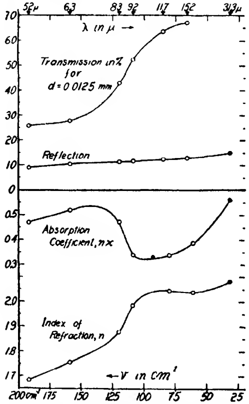

FIG 1

From our measurements, we conclude that the molecules in water are bound in a quasi-crystalline lattice and execute only partial rotation in agreement with Debye's hypothesis Free rotation is hindered by a torsional constant of approximately $5kT$, and the fundamental frequency for an oscillation about the axis of greatest moment of inertia occurs at about 140 cm.$^{-1}$ (70μ).

Predissociation in the Third Positive Group of CO

IN a former communication[1] we recorded the discovery of a predissociation in the upper level ($B^1\Sigma$) of the Angström bands. For the energy of the dissociation state responsible for this predissociation, we found a value of 11 08 volts above the normal state of the molecule

In their investigation of the third positive group of CO, Dieke and Mauchly[2] noticed that these bands, the common initial level of which is the O vibrational state of $b^3\Sigma$, can be traced to $K = 54$, $K = 55$, $K = 56$ for the R-, P-, and Q-lines respectively Examining the $0 \rightarrow 1$ band of this system on my own plates, it appeared to me that, at these rotational quantum numbers, a disappearance (or at least a very strong decrease in intensity) of the band lines occurs This points to a predissociation in the $b^3\Sigma$ level at $K = 55$ caused by a dissociation level with an energy of $11 08 \pm 0 01$ volt above the normal state This is obviously the same dissociation state as that which causes predissociation in the $B^1\Sigma$ level of the Angström bands referred to above

Stark Splitting of the ^6S Level of the Manganous Ion in Crystalline Fields

IN recent papers, Kramers, Bethe and Van Vleck[1] have discussed theoretically the possibility of a weak Stark splitting of the ^6S levels of Mn^{++} and Fe^{+++} ions in crystalline fields As Van Vleck has shown, such a splitting would lead to two important consequences in the magnetic behaviour of these ions in crystals: (1) it would produce a feeble magnetic anisotropy in the crystal, (2) the temperature dependence of the three principal susceptibilities of the crystal would not exactly conform to the simple Curie law The first effect, namely, the magnetic anisotropy, can be measured accurately, and can indeed be used, as Van Vleck has pointed out, as a means of calculating indirectly the magnitude of the Stark separation

Using the special experimental arrangement designed by us for measuring feeble anisotropies[2], we have recently measured the anisotropies of a number of manganous salts of the Tutton series, $MnSO_4 . A_2SO_4 . 6H_2O$, where A = NH_4, Rb, Cs, Tl, $MnSeO_4 . A_2SeO_4 . 6H_2O$, where A = NH_4, Rb, Tl The differences $\Delta\chi$ between the maximum and the minimum gram molecular susceptibilities of these crystals at about 25° C. range from $11 \cdot 4 \times 10^{-6}$ (C.G.S E M U.) in manganous ammonium sulphate to $7 0 \times 10^{-6}$ in manganous cæsium sulphate For all the crystals the mean of the three principal susceptibilities is about $14,000 \times 10^{-6}$

Part of this anisotropy must be attributed to that of the *diamagnetism* of the crystal. This may be taken, to a first approximation, to be the same as the anisotropy of the corresponding diamagnetic Tutton salt obtained by replacing Mn by Mg. (The anisotropies of the latter salts are found to range from $2 \cdot 5$ to $0 \cdot 9 \times 10^{-6}$) A further correction is also necessary for the anisotropy arising from the mutual influence of the magnetic moments of neighbouring Mn^{++} ions, which are not arranged in a cubic lattice

After making these corrections, we find that the residual anisotropies of the manganous salts correspond to a Stark separation of the ^6S levels of only a small fraction of a cm $^{-1}$

Raman Spectrum of 1.3.Cyclohexadiene

WE published in May last year[1] an account of the Raman spectrum of 1 3 cyclohexadiene (obtained by the Harries-Willstättor method) Another method for the preparation of that compound is that of Crossley[2] However, Harries[3] first and Willstätter and Hatt[4] afterwards stated that the 1 3 cyclohexadiene prepared in accordance with Crossley's method was very impure as regards cyclohexene, bromocyclohexene and benzene On the other hand, Willstätter[5] stated that a pure 1 3 cyclohexadiene can be obtained with his method In Fig 1 we give the position of the Raman lines of the two samples of 1 3 cyclohexadione prepared by us using these two methods

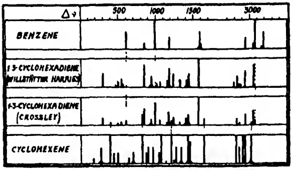

FIG 1

1.3 *cyclohexadiene* (prepared by the Harries-Willstätter's method): 292(2½), 468(0), 501(1); 553(1½); 568(½), 843(4), 940(2*b*), 1010(½); 1053(1), 1145(1½), 1171(3½*b*); 1235(2½); 1321(1½); 1408(1½*b*); 1432(2½*b*), 1574(10), 2789(1); 2829(2); 2860(½); 2879(½); 2946(3), 3051(4)

1 3.*cyclohexadiene* (prepared by Crossley's method): 292(1½), 389(½); 498(0); 548(½); 605(½); 822(2); 846(3), 940(1½*b*), 992(4); 1056(1), 1148(½), 1174(2½*b*); 1220(1); 1235(1½), 1321(½); 1408(1½*b*), 1431(2*b*), 1574(10); 1648(1½); 2827(1½); 2872(1), 2940(2), 3029(½); 3049(3), 3067(1).

It can be seen from Fig 1 (as can likewise be inferred from examination of the published values) that some of the extra lines given by the sample prepared by Crossley's method, belong to the Raman spectrum of benzene, and others to the Raman spectrum of cyclohexene. Hence Willstätter's observation is confirmed, namely, that the 1 3 cyclohexadiene when prepared by Crossley's method has many impurities, amongst which are benzene and cyclohexene.

Since the double bond line of the 1.3 cyclohexadiene is more displaced towards smaller frequencies than the known line at 1584 cm.$^{-1}$ in benzene, and since it is near the latter in spite of the enormous differences in the saturation characteristics of the two compounds, the interpretation of the line 1584 cm.$^{-1}$ of benzene as being due to a double ethylenic bond in the ordinary meaning of organic chemistry would appear to be very doubtful

Crystal Structure of some Alkali Tungsten Chlorides

ABOUT twenty years ago, O. Olsson-Collenberg[1] synthesised a series of alkali tungsten chlorides with trivalent tungsten of the general formula $M_3W_2Cl_9$. Later, Collenberg and Sandved[2] found that water solutions of these compounds contain the complex ion W_2Cl_9. An X-ray analysis of these chlorides has now shown that this ion is present also in their crystals.

The ammonium, potassium, rubidium, cæsium and thallium compounds are all isomorphous and crystallise in the space-group C_{6h}^{4}. The unit cell of $K_3W_2Cl_9$ has the dimensions $a = 7{\cdot}16$ A., $c = 16{\cdot}16$ A. and contains two molecules. Using Wyckoff's notation, the atomic positions are:

2 K at 2(*a*), 6 Cl at 6(*h*), ($u_3 = 0{\cdot}45$, $v_3 = 0{\cdot}44$)
4 K at 4(*f*), ($u_1 = 0{\cdot}31$). 12 Cl at 12(*i*), ($x = 0{\cdot}12$, $y = 0{\cdot}35$, $z = 0{\cdot}16$). 4 W at 4(*f*), ($u_2 = 0{\cdot}076$)

In this structure the W_2Cl_9 groups have the configuration shown in Fig. 1. Their centra form a lattice of the close-packed hexagonal type.

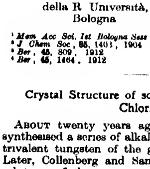

FIG. 1. Configuration of W_2Cl_9 group in $M_3W_2Cl_9$. ○, Cl; ●, W.

It is of interest to compare this structure with that of $Cs_3As_2Cl_9$ recently determined by Hoard and Goldstein[3]. The latter contains no ions As_2Cl_9, and the complex arsenic chlorides seem thus to be of a different kind from the tungsten chlorides of analogous composition.

A complete report of the structure determination will be given in the immediate future, and the investigation will be extended to embrace also the tungsten chlorides with metal-ammonia and partly organic cations.

The Spinels and the Cubic Sodium-Tungsten Bronzes as New Examples of Structures with Vacant Lattice Points

X-RAY studies, carried out in this Institute, have shown that when the spinel, $MgO.Al_2O_3$, dissolves Al_2O_3, the oxygen excess is caused by the occurrence of vacant points in the metal lattices. In accordance with this, γ-Al_2O_3, the unstable limit of these solid solutions, represents a spinel lattice where 1/9 of the metal positions are vacant.

In the same way it has been shown that when Fe_3O_4 is oxidised to γ-Fe_2O_3, this process is accompanied by the occurrence of vacant points in the Fe lattice so that only 8/9 of them are occupied in γ-Fe_2O_3. At the same time the lattice dimensions decrease. The presence of vacant points has been definitely shown by measurements of both the intensities of the interferences and the densities of the preparations.

The general formula of the sodium-tungsten bronzes has been shown to be Na_xWO_3. In the gold yellow bronze, x is 1 and the cube edge $= 3{\cdot}850$ A. This bronze contains W^{+5} ions and crystallises in a complete perowskite lattice. The deepening of the colour from yellow through red to blue is accompanied by a continual decrease in sodium content and dimensions. With decreasing values of x, vacant points occur in the original Na lattice and in the blue bronze ($x = 0{\cdot}3$–$0{\cdot}4$, $a = 3{\cdot}813$ A.), about two thirds of the original Na positions are empty. At the same time, W^{+6} ions occur and the increasing amount of these ions is probably the cause of the deepening of the colour.

The above 'subtraction phases' represent, quite as much as the 'addition' or 'interstitial' phases, solid solutions with a variable number of atoms per unit cell. It is a mere matter of convenience if such a phase is termed a 'subtraction' or an 'addition' phase. In all cases where a variable number of atoms has been found, the structure is built up by large atoms or ions (in most cases anions, and especially oxygen ions). The atoms, which vary in number, are always comparatively small and placed in the interstices of the skeleton formed by the large atoms. A variation of their number is possible if the structure is of a non-polar type (hydrides, carbides, nitrides of many transition elements), if ions are substituted by other ions with another charge ($MgO.Al_2O_3 \rightarrow \gamma$-$Al_2O_3$, tremolite $\rightarrow$ hornblende, β-cristobalite $\rightarrow$ α-carnegieite, $AgI \rightarrow Ag_2HgI_4$), or if the lattice contains ions which are able to change their charge (especially in lattices containing transition elements, for example, $Fe_3O_4 \rightarrow \gamma$-$Fe_2O_3$, the cubic Na-W-bronzes).

More detailed reports of these investigations will be published elsewhere.

Bio-Electric Transients during Fertilisation

IN 1909 R. S. Lillie[1] suggested that the activation of the unfertilised egg by a spermatozoon or by a parthenogenetic agent might involve the temporary depolarisation of the cell surface, the process being similar to that observed in stimulated nerve or muscle. This so-called 'physical' theory of fertilisation and parthenogenesis has been elaborated by Gray[2],

who differs from Lillie in considering that there is no recovery after the depolarisation as there is in nerve, muscle and certain plant cells Confirmatory evidence of this has been produced by Gray[2], who has shown that fertilised sea-urchin eggs have a higher conductivity than unfertilised eggs (These results have recently been criticised on theoretical grounds by Cole[4])

One of us (V R.)[5] has shown that the activation of the unfertilised frog's egg by trauma is associated with the propagation of an action potential over the egg surface. The action potential differs from that found in nerve or muscle in that there is no recovery phase.

We have continued these experiments, substituting a spermatozoon for the micro needle Two electrodes held in two Péterfi[6] micro-manipulators were placed at opposite poles of the animal pole of the frog's egg, localised fertilisation near one (grid) electrode was effected by means of a micro pipette filled with sperm held in another Peterfi micro-manipulator The electrodes were connected to a Matthews'[7] oscillograph used in conjunction with resistance capacity-coupled amplification

There are strong indications that the attachment of the spermatozoon to the egg results in an action potential being propagated over the egg surface, the action potential again being characterised by having no recovery phase The change is considerably slower than that observed in stimulated nerve or muscle, and for this reason capacity coupled amplification is unsatisfactory, as the rate of discharge of the coupling condensers is great compared with the rate of change of the action potential Considerable distortion is therefore inevitable

We propose to continue these experiments during the next frog-breeding season using battery coupled amplification in order to obtain quantitative data

Response of the Leech to Acetylcholine

THE work of Dale, Feldberg and others shows in a striking way that, in the Vertebrata, excitation is transmitted from nerve to effector through the mediation of either acetylcholine or of adrenalin, according to the mode of innervation[1] A sensitive test employed for the presence of acetylcholine is its power to cause contraction of the longitudinal muscle of the body-wall of the leech *Hirudo medicinalis* I wish to direct attention to the fact that this sensitivity of leech muscle completes a very remarkable picture disclosed by J F. Gaskell[2]

In the leech and other annelids, the nervous control of the vascular and the 'voluntary' muscular systems shows a detailed parallelism to those same systems in the Vertebrata. In *Hirudo*, the contractile blood-vessels receive a double innervation of accelerator and depressor nerves which modify their rhythm Adrenalin accelerates the rhythm, and the central nervous system contains chromaffine cells analogous to those of the vertebrate sympathetic. In the same way, the vago-mimetic drug muscarin depresses the rhythm, and this action is antagonised by atropine.

The longitudinal and circular muscles of the body-wall do not respond to adrenalin, and can be paralysed by curare This evident parallel to vertebrate skeletal muscle is now completed by the responsiveness of the muscle to acetylcholine

A physiological similarity of such intricacy between members of such distant phyla as the Vertebrata and the Annelida is most impressive It seems possible that 'cholinergic' and 'adrenergic' transmission of excitation demonstrated in vertebrates may be widespread among the cœlomate phyla, a view supported by the general similarity of action of adrenalin and other drugs among different animals

A Tame Platypus

MORE than a year ago I recorded the successful rearing of a platypus by Mr R Eadie at Healesville, Victoria[1], the animal has now been in captivity 740 days It was probably five months old when captured, and was then 15 inches long and weighed 48 ounces avoirdupois It is now 21 inches long and weighs 72 ounces Its daily diet is 18 ounces of worms and two eggs, specially prepared During the period of captivity it has consumed 700 pounds of worms and 1,300 eggs, most of them duck eggs. It has also eaten thousands of tadpoles and large quantities of grubs. Whether this is a balanced diet or whether in the wild state it finds something else to eat remains to be investigated But the success of the experiment so far seems unique

It is still more satisfactory to note that, owing to the protection given and the interest taken, the platypus in the streams appear to be increasing in number. Mr Lewis, chief inspector of fisheries and game, is to be congratulated on the effective protection afforded

Sounds Made by Fishes in the East Indies

I WAS interested to read the notes on this subject in NATURE of November 17, 1934, and March 16, 1935

Although I have not heard the sound made by *Therapon*, whilst collecting in Singapore waters some years ago I was introduced to a similar phenomenon caused by fishes of the family *Sciænidæ* (probably of the genus *Otolithus*) The Malay name of these fishes is *gêlama.* The first time I heard these sounds I was in the company of Mr W Birtwistle, of the Malayan Fisheries. The best results were obtained by applying the ear to the rail of the launch The sounds might be described as a 'chirping' or intermittent hum

Mr C Boden Kloss, until recently Director of Museums in Malaya, writes (*in litt.*) of a similar experience off Batticaloa in Ceylon He refers to the sound as "piping . something like the note of the Singapore bull-frog made fluty and musical"

The name given by the Malays to some fishes of the genera *Therapon* and *Centrogenys* is *kĕrong-kĕrong*, *mĕnkerong* or *tĕnkerong*[1]

Dr. C. O Blagden, of the School of Oriental Studies, tells me that the meaning of *kĕrong* is a deep metallic or booming sound, and agrees with my suggestion that it is of onomatopoeic origin. This would account for the Malay name of Dr Hardenberg's fish, and show that the phenomenon is known to the natives (I have not been able to see a copy of Dr Hardenberg's paper so do not know whether he has discussed this)

On the east coast of the Peninsula the Malay fishermen employ a *juru sĕlam* (literally 'diving expert', *fide* Dr Blagden) He dives under the surface, listens for the fishes, and is said to be capable of guiding the boats. His activities (an account of which appears in a report by Mr Birtwistle issued, if memory serves, about 1928) have been looked upon with a tolerant incredulity by Europeans in Malaya In view of the above, however, it appears that they may have at least a basis of fact

Activation of Cambial Growth by Pure Hormones

In a recent letter to NATURE[1] it was reported that strong cambial growth can be activated in young decapitated sun-flower seedlings by inserting their upper ends into tubes containing a weak solution in gelatine of the ether-soluble component of urine With a similar method it has now been found that strong cambial growth can be activated by solutions of pure auxin *a* and of pure β-indolyl-acetic acid (called by Kögl[2] 'hetero-auxin') at concentrations of 1 or 2 in 10^6. The auxin-*a* was kindly sent by Prof Kögl from Utrecht, and the hetero auxin was kindly synthesised by Dr Weisberger at the Dyson Perrins Laboratory, Oxford The cambium formed was in the normal position, and it extended for at least three centimetres below the part to which the hormone was applied Controls had formed no cambium, or scarcely any

Thus the same hormones, auxin *a* and hetero-auxin, which promote the elongation of stems and coleoptiles, also activate growth in thickness by divisions of cambial cells, besides activating root-formation[3,4] and producing various other effects. According to Kögl[2], auxin-*a* is the hormone formed by the tips of grass seedlings, whereas hetero-auxin is formed by yeast. For experiments on growth, the use of pure hetero-auxin, which can be synthesised in ample quantities, should prove very valuable.

Tetraploid Sweet Peas

Lathyrus odoratus has been classical material for genetic study ever since the rediscovery of Mendel's work But up to now, no chromosomal aberrations of any kind have ever been found. The sweet pea, in common with all other species of *Lathyrus* hitherto investigated, has seven regular bivalents at meiosis It is therefore of interest to report here the first discovery of tetraploidy in this plant

In a family growing at this Institution, Miss C Pellew noticed a plant with constricted pods, such as are typical of the half-sterile heterozygous trans location plants in *Pisum* The plant was very vigorous and set a large number of pods which, however, contained but few seeds—never more than four, instead of the usual 8–12 Owing to the lateness of the season, no preparations of pollen mother-cell divisions could be made, but mitoses were found in petals and sepals which showed the plant to be tetraploid The root-tips of ten seedlings obtained by selfing this plant were examined cytologically, and in every case a complement of 28 chromosomes was found

The family in which the tetraploid plant appeared was an F_2 segregating for four recessive factors copper, acacia, glabrous and dull—the last three being in one linkage group The tetraploid plant was dominant for all four genes, it is thus not improbable that some factors will be available for the study of tetrasomic segregation in sweet peas.

Inhalation of Carbon Dioxide at High Altitudes

THE suggestion put forward in NATURE of March 23 (p 457) by Prof Yandell Henderson and others to the effect that carbon dioxide might be of use in high altitude climbing reminds me of some trials carried out about ten years ago. Messrs Siebe Gorman and Co., Ltd, had similar ideas, and they lent me a rebreathing mask to try out in the Alps I went up to the Margherita hut on Monte Rosa, to all intents 15,000 ft, to test it I was in fairly good training at the time, but had not been above about 12,000 ft that summer For trial purposes this was all to the good, as I became rather blown during the last thousand feet, having walked up fast to the 14,000 ft level It may therefore be assumed that I was partially but not fully acclimatised.

The moment I started to rest at the hut I felt perfectly fit, and after lunch I lay down for 20 minutes or so, before starting the test I then noted pulse and respiration rates, put on the mask and noted them again. I have not a record of the figures handy, but can definitely state from memory that there was an almost immediate drop of 20–25 per cent in each rate

I am afraid I did not try the mask while walking uphill; but a device which weighs fewer ounces than a gas bottle weighs pounds might be worth thinking seriously about On the other hand, it is quite possible that it might defeat its own object, by supplying carbon dioxide at the expense of oxygen However, the experiment is so simple that it should be tried

while going uphill, care being taken to adjust the capacity of the mask so that the most advantageous volume of air is rebreathed The mask I used was adjustable in this respect The mask should be so designed that the capacity can be recorded Mine was not, and I probably opened it about half way and chanced the result

Incidentally, I might record the experiences of two well known British climbers I think during the same summer One had the idea that carbon dioxide was the solution of the high altitude problem, got some bombs charged with it and persuaded his friend to come and test them on Monte Rosa The proposal was to test them before becoming acclimatised, and so they travelled out to the Alps and straight away crossed Monte Rosa to the Margherita hut On arrival there they were so done that they had to receive medical attention and were glad to get down with the bombs untested One was laid up for a week afterwards This agrees with Prof Henderson's note about the two men who had walked up Pike's Peak without getting into condition first of all

Control of Dunes

THE arid south east corner of the Mediterranean basin has been desolated by sand dunes increasing during the last few centuries and ever smothering more and more of a fertile border of Sinai and Palestine The means for control can be seen in existing vegetation

Examination of irregular palm groves shows that a belt three palms wide, about 80 ft, entirely arrests dune advance, by acting as a friction clutch on the upper wind beneath which the ground flow of sand haze cannot be formed Eventually a dune may pile up until it slides down and covers the front palm stems but the tops still keep a wind clutch Pockets of palm grove become enclosed when dunes flow on both sides, but they still maintain a clear ground beneath covered with small plants A gap of 100 ft in a belt lets a dune through, and even 50 ft is precarious

Besides arresting the front of dunes by palms, the gathering ground behind can be checked by lines of *Opuntia*, which will grow on the sand Such a line will hold up 10 ft depth of sand, growing up as the sand rises Though dangerous in unoccupied Australia, there is in Palestine such a pressure of occupation that there is full control Fig is useful to stop ground flow, but does not grow unless some organic soil is within reach of the roots

A Sine Curve Crack in Natural Ice

IN January of this year, an interesting phenomenon was observed on Lake Bohinj in the Julian Alps This lake, in the extreme north west of Yugoslavia is a typical alpine lake, its basin having been hollowed out by a diluvial glacier Its altitude is 523 m it is about 4 km long and 1 km wide In winter the lake is thickly frozen over and last winter was no exception Acute tangential tensions always set up in the ice crust and find adjustment in various cracks which extend over the entire width of the lake in straight or broken lines, as the case may be As a rule the cracking of the ice is accompanied by a powerful detonation which can be heard distinctly for a distance of several kilometres

On January 4 Mr F Avčin noticed a peculiar crack in the ice It extended across the entire lake and was about one kilometre in length Near the southern shore its course was curved and then followed a straight line to the opposite shore The crack itself however was in the form of an almost perfect sine curve (Fig 1) The wave length of

FIG 1 Sine curve crack in the ice of Lake Bohinj

this curve was about three metres its amplitude about 0 5 m The ice was about 15 cm thick The crack was about 10 cm wide and on January 4 a thin crust of new ice had already formed upon it There were several other cracks in the ice but all of them normal that is straight They too were newly frozen over and therefore appeared to be of the same age as the sine curve crack

It is suggested that the detonation caused by the occurrence of one of the normal cracks liberated the tensions in the sine curve crack The percussion started by the cracking of the ice travelled through the ice in the form of longitudinal vibrations Periodically alternating condensations and attenuations passed across the crack as it was being formed in a straight line Might not the combination of these two phenomena furnish the explanation of the sine curve track of the crack? I am indebted to Mr F Avčin for the photograph and description of this strange phenomenon

Davy's Experiments on the Frictional Development of Heat

IN NATURE for March 9, 1935 (p 359), Prof Andrade directed attention to the persistent text book errors concerning Davy's experiments on the frictional development of heat, pointing out, among other things, that the much quoted experiment on the melting of two pieces of ice by rubbing them together was not carried out in a vacuum It may be of some interest to inquire how Davy produced and maintained the vacuum for the first experiment, in which a gunlock was fired, and for the third experiment, in which wax was melted by the heat developed by the friction of a wheel rotated by clock work against the plate carrying the wax Davy gives no details of his vacuum apparatus, but refers to the "exhausted receiver" of an "air pump" In the first experiment the trigger of the gunlock was snapped, he says, by this means "A slight iron wire was affixed to the trigger, brought through a hole made in the centre of the stand [supporting the receiver], and cemented into the hole with wax, so as to exclude entirely atmospheric air from the receiver"[1] Presumably the same device was used in the third experiment to start the clockwork

In neither case would a vacuum be maintained As for the apparatus by which the vacuum was produced, it appears to have been an 'air pump' with a curious history, indeed, a curiosity itself Davy had shown some kindness to the surgeon of a French ship wrecked at the Land's End, and in return the latter gave him certain instruments, including a glyster or enema syringe, which Davy converted in some way or other into an air pump This account is given by Paris[2], who states that he obtained it from Thomas Giddy of Penzance John Davy, however, in writing his brother's biography, discredited Paris's story of the syringe, alleging that "Mr Giddy probably had it from some facetious person who wished to amuse him . because no one belonging to our family ever heard of this instrument, or of the French surgeon, or of the shipwrecked French vessel off the Land's End, so circumstantially noticed in Dr Paris's lively narrative"[3] While Paris's account is reasonably credible in view of the scant facilities likely to be available to a youth of nineteen in such a remote part of the country as Penzance, John Davy's denial is not improbable due to his extensive irritation with Paris's Stracheyan sense of a biographer's duties

Identity of Calycopterin and Thapsin

A YELLOW colouring matter with powerful anthelminthic properties has recently been isolated[1] from the leaves of *Calycopteris floribunda*, Lamk., and the constitution of a dihydroxytetramethoxyflavone ascribed to it. Since it yielded *p*-hydroxybenzoic acid by degradation with alkali, it became obvious that all the six positions of the fused benzene ring were occupied and the substance was a remarkable instance of a pentahydroxybenzene derivative occurring in Nature Demethylation gave a new hexahydroxyflavone, 'calycopteretin'.

While this work was going on, one of us[2] obtained a by-product, thapsin, in the preparation of digitoxin from a dried and powdered specimen of the leaves of a Spanish *Digitalis*, the botanical source of which was uncertain, but was very probably derived from *Digitalis thapsi*, L The independently described properties of calycopterin and thapsin are very similar and direct comparison of the two substances and their dimethyl ethers has shown their complete identity The occurrence of a flavone with so unusual an orientation of hydroxyl and methoxyl groups in two plants belonging to widely different natural orders (one to the Combretaceæ and the other to the Scrophulariaceæ) is worth notice

With regard to the slight precedence in point of time, we suggest that the name calycopterin may be retained for the flavone constituents of both *Calycopteris floribunda* and *Digitalis thapsi*

Philosophical Interpretation of Science

WHILE it is true that Prof Dingle[1] and I can finish this discussion in private, it seems to me there is a public importance in differentiating the two schools of thought One school claims that science is an historical phenomenon produced by human beings in their handling of the world of which they are parts, a social practice with technological, experimental and theoretical aspects all interlocking and interdependent Scientists it sees as individuals consciously or unconsciously fulfilling the social purpose of science even when they are personally interested only in developing its logical framework I agree with that view of science

There is the other school that sees science simply as the organisation of our experiences in logical form Prof Dingle even goes further than this for he asserts that "the logical network *is* the external world", and he believes this to be a consequence of scientific discovery It was this to which I took exception, and I doubt whether either Einstein or Bohr, whom he has quoted in support, would underwrite this Be that as it may, the first view sees science in its social context, sees it socially conditioned, and keeps the scientist alive to the social consequences of his work The second view banishes the world into a set of logical ideas. The first view says that science and philosophies are produced by man, are manifestations of his social behaviour and therefore exist with him in the external world. The second view leads Prof Dingle to say "It certainly never occurred to me to claim that the external world contained philosophies". The two schools evidently speak different languages

Nova Herculis, 1934

AFTER dropping in brightness at the end of April to about mag 13, this star has brightened markedly again A spectrogram secured by an 8-hours exposure spread over two nights, May 17–19 (with the star's magnitude at 10 6^m–10 2^m) shows a complete change of spectrum The lines of Fe II and [Fe II] have vanished, and the lines of [O I] are much weaker The hydrogen lines are stronger again and N II, [N II] and He II are all represented The strongest lines are now the well known nebular lines of [O III] at 5007, 4959 and 4363 At an earlier stage (late in March) bright bands appearing simultaneously at 4360, 5006 were identified as [O III] lines. As the changing spectrum developed, it became clear that these bands were due to [Fe II] and N II respectively. The presence of a bright line at 4959 and the absence of [Fe II] show that the [O III] lines are now present This transformation to the spectrum of a planetary nebula and nucleus is typical of novæ

Points from Foregoing Letters

BY successive electrolysis of water and the recombination of the hydrogen and oxygen, Messrs W N Christiansen, R W Crabtree and Prof T H Laby have obtained 'light' water free from the heavy variety, and find the density to be 12 7 parts per million less than that of ordinary water The authors remark that the partial separation of 'heavy' and 'light' water which takes place during distillation produces a noticeable difference in the density of the first and last portions of fractionally distilled water

New polarographic tests, depending upon the polarisation produced at a dropping mercury electrode in contact with solutions containing compounds of manganese and of rhenium, have convinced Prof J Heyrovský that the effects which he and Mr V Dolejšek had previously attributed to the presence of rhenium in commercial manganese salts are really due to other impurities

Injection of mannose into rats leads to an increase in the content of anti scorbutic vitamin (ascorbic acid) in some of their tissues, according to Messrs B C Guha and A R Ghosh The ovarian tissues of the pregnant guinea pig and the guinea pig embryo as well as the ovary of an adult non pregnant monkey were also found capable of converting mannose into ascorbic acid *in vitro*

The amount of ascorbic acid found by titration in certain vegetables is greater after boiling or treating with hydrogen sulphide Messrs E W McHenry and M L Graham infer that ascorbic acid may exist in these vegetables in three forms free, combined as an ester, and oxidised Only the first form is estimated when these vegetables are extracted with trichloracetic acid, and the extract titrated against phenolindophenol indicator

Mr C H Cartwright finds that water has an anomalously high absorption for infra-red radiation of wave-lengths just below 90μ and he deduces, in accordance with Debye's hypothesis, that the molecules in water are bound in a quasi crystalline lattice and execute only partial rotation

From measurements of the anisotropic magnetic susceptibilities of manganous salts, after allowing for the diamagnetism of the crystals, Messrs K S Krishnan and S Banerjee conclude that only a small Stark effect (splitting of spectrum lines or radiation quanta in an electric field) may be expected in the ^6S level of the manganous ion, in the crystalline field

Results of analysis of light scattered by 1.3 cyclohexadiene, a substance related to the terpenes, constituents of many ethereal oils, obtained by Messrs. G. B Bonino and R M Ansidei, confirm that, when the compound is prepared by Crossley's method, it contains various impurities, among which are benzene and cyclohexene

X-ray analyses of crystalline alkali tungsten chlorides of the general formula $M_3W_2Cl_9$ show that the complex ion W_2Cl_9, found in their solutions, is also present in the crystals Mr C Brosset gives the crystallographic constants of $K_3W_2Cl_9$ and points out that the corresponding arsenic compound $Cs_3As_2Cl_9$ contains no As_2Cl_9 ions

Messrs T Péterfi and V Rothschild report that when a spermatozoon attaches itself to the frog's egg in the process of fertilisation there are indications of an electrical change (action potential) propagated over the egg surface V Rothschild had previously observed that when the unfertilised egg is 'activated' by pricking, a similar action potential is propagated

Mr C F A Pantin directs attention to the fact that acetylcholine, adrenalin and other drugs act upon the nerve and the muscle cells of the leech in the same way as they do upon corresponding cells of the higher animals

Further evidence that the hormones auxin-*a* and hetero auxin activate growth in thickness of decapitated sunflower seedlings, by increased division of cells of the cambium, is adduced by Mr R Snow The same hormones are known to promote the elongation of stems and of germ-sheathes of grasses, and to activate root formation, etc Auxin *a* has been obtained from the tips of grass seedlings and hetero-auxin from yeast and they have also been prepared synthetically

The occurrence of a sweet-pea mutation with double the normal number of chromosomes is reported by Mr A C Fabergé, who describes some of the characters of the new variety

Mr P J. H Unna describes his own and two other climbers' experiences while attempting to test the suggestion that inhalation of carbon dioxide might be useful in high altitude climbing

Sir Flinders Petrie indicates the conditions under which the palm tree and the prickly pear cactus (*Opuntia*) are useful in preventing the advance of dunes in Sinai and Palestine

Calycopterin and thapsin, the former (a vermifuge) obtained from the leaves of the climbing Indian plant *Calycopteris floribunda*, and the latter obtained from Spanish fox-glove, are chemically identical Mr W Karrer of Basle and Mr K Venkataraman of Bombay, who originally described the properties of these two substances separately, now announce their identity in a joint letter

Research Items

Early Man in Uganda. Mr E J Wayland, as a preliminary to a Geological Survey Memoir to be published in the course of the current year, has summarised in chronological order the main features of his studies in Uganda since 1919 with reference to its prehistory (*J Roy Anthrop Inst*, 64, Pt 2) The prehistory of a country is no longer merely a question of culture sequences and human types, but has now been enlarged to include the physical conditions, their changes and the effects of these on human activities In Uganda there were not only great changes of climate during Pleistocene days, but also of topography and hydrography, consequent upon powerful earth-movements, of which the Rift Valley and Victoria Nyanza are two visible expressions Two pluvials are claimed in the Pleistocene and in each of them is an intrapluvial period, while the post pluvial period is punctuated by two spells of moister climate They are separated by a relatively dry break and preceded by a more pronounced swing towards aridity Earth movements are recorded at three points, to the most recent of which the present configuration of the Rift Valley and the lake and the flow-direction of the river system are due Equated with these events of the Pleistocene are Stone Age cultures With Pluvial I are associated Early and Later Kafuan In the following interpluvial, lakes dry up The early part of Pluvial II is associated with Pre-Chellean and Protosangoan, followed by Chelleo-Acheulean and Early Sangoan It is correlated tentatively with Riss An intrapluvial follows associated with Acheulean, a valley culture, and Full Sangoan, a hill culture Pluvial II, correlated with Wurm, is associated with Mousterian and Lower Aurignacian, followed by Still Bay and Upper Aurignacian, respectively The Aurignacian has the appearance of a foreign origin, presumably from the north or north east From the Aurignacian arise microlithic industries, such as Magosian and Wilton, a dying Still Bay influence being discernible in the former These are post pluvial and are correlated tentatively with the Achen retreat and Bühl stadium In Uganda, pottery appears first with Wilton

Polynesian Mythology A number of legends concerning Maui and Tahaki, the former the central figure of Polynesian mythology, from the island of Fagatau of the Tiamotu Archipelago, are published with a translation by J F Stimson (Bull 127, Bernice P. Bishop Museum, Honolulu) The legends of Mauri and Tahaki are found throughout Polynesia, the well-known legend of Maui being one of the most widespread of the pre-distribution myths The principal Tahaki theme, the voyage to the underworld to avenge Hema, is fairly consistent throughout Polynesia, but the incidents composing the plot differ markedly in different localities The material now published is derived from the narration of Farua-a-Makitua, a former chief of Fagatau and inheritor of the esoteric lore of Kamake, the greatest of all Tuamotuan sages. His wife Reva refused to receive the ancient teaching of Kamake as being "heathenish nonsense" and her version of the legends is not included as probably being affected by Christian influence Chants are interspersed throughout the narrative These are mostly of an erotic character, and have been included only when they form an integral element in the progression of the myth. The music of these chants, as sung by Reva, has been analysed by E G Burrows Verbal rhythm dominates the musical rhythm (the contrary of European song) and a further irregularity is due to the pauses The accent corresponds to $\frac{2}{4}$ time in European notation The simple irregular rhythm of the chants, their narrow tonal range and prevailing monotone, and the quavering endings are widespread, and presumably ancient, in Polynesia

Hair-Tracks of Australian Aboriginals. A detailed account of the lie of hair upon the bodies of Australian aboriginals, made by Dr J H Gray, suggests that the hair-tracks are highly characteristic of the race, and that they constitute a striking departure from the human hair pattern hitherto accepted as normal (*J Anat*, 69, 206, 1935) The differences are connected with the presence of centripetal hair-whorls on jaw and back, and reversals of the normal hair trend on the posterior of the thigh and on the back Dr Gray is inclined to correlate the peculiar reversals with characteristic habits peculiar to the aborigines The dorsal reversal he associates with gravitational and other forces involved in the maternal carriage of children upon the left hip, and the anti clockwise spiral with the support given by the mother's left arm while the child is being carried The disturbances of pattern upon the posterior aspect of the thigh he thinks may be brought about by the squatting habits of the aboriginals In the fœtus, the descriptions so far made have indicated no departure from the normal in the hair-tracks But before the idea can be accepted that habits alone can produce in each generation uniform and characteristic hair-patterns, more would have to be known regarding the hair tracks in other primitive races

Spines of a Spinous Rat. Specimens of the spinous rat of Amami (*Rattus jerdoni osimensis*, Abe) have been examined by Yosio Abe, particularly as regards the curious spines which project beyond the normal fur (*J Sci. Hiroshima Univ*, 3, 107, Dec 1934) Contrary to what has been suggested as regards the spines of other species, these do not appear to be shed in winter, nor are they noticeably fewer in younger animals Their arrangement in the skin shows that they correspond in a hair group to a *Mittelhaare*, and this indeed may be a spine in some groups, and in others an ordinary overhair A tendency in one direction or the other means the difference between a richly-spined and a poorly-spined individual In transverse section the spines are flattened and strongly curved in at the sides, and although at their place of origin they contain a well-developed medulla, the subsequent constriction has the effect of restricting the medulla to the thickened edges

Some Laurentian Copepods. Prof. Arthur Willey has recently discussed the variations of certain copepods which are of much interest (*Trans Roy. Canad. Inst*, **20, Part 1, 1934**). **In a letter to NATURE of August 8, 1925,** he briefly described a new copepod ***Canthocamptus hiatus*** from a swamp beside the Nikaban

River. This species has now been found again in water accumulating in the funnel-shaped leaves of the pitcher plant, *Sarracenia purpurea*, in Quebec The fifth foot is peculiar in having only five marginal bristles instead of the usual six and is distinguished as the *forma uxeolicola*, the more northerly form being the *forma paludicola* It is made the type of the new sub-genus *Pentacamptus* Each form is found associated with a different species of *Cyclops* Several more species of *Canthocamptus* are re-described and variations noted There is a general similarity in the nature of the variation, and at the same time some parallelism as well as mere identity between European and trans-Atlantic species and races In *Cyclops vernalis* and *C venustus* the variations are of different kinds, although the species are fairly closely allied and live together in a small space under identical conditions They were found in a small spring in almost pure culture when the rest of the countryside was covered with a thick mantle of snow and ice in the foothills of the Laurentians A single ovigerous female of the rare *Cyclops modestus* was found in water poured from the submerged introrse leaves of the yellow water lily

Penæidæ of Louisiana Mr Martin D Burkenrood has continued his studies on penæids (*Bull Amer Mus Nat Hist*, **68**, 1934), a companion paper having appeared a few months ago (Bingham Oceanographic Collection, 4, 7, 1934) The present investigation is mainly confined to the eastern portion of Louisiana, and the material is estuarine and littoral It is very satisfactory that the importance of the larval history is realised The classification is thus based on the structure of both adult and larva Four sub-families of the Penæidæ are recognised and these are discussed particularly in the light of larval history The Aristæinæ and Solenocerinæ show close affinities and are contrasted with a second group composed of Penæinæ and Eusicyoninæ All the descriptions are detailed, and great care has been taken in the examination of all essential characters It is interesting that the author is of the opinion that in all Penæidæ the pleurobranchs are the last gills to appear in larval development He finds that "postmysis larvæ of Penæinæ completely lack pleurobranchs and are indistinguishable in this from larval Eusicyoninæ, in the further course of development, the Penæinæ add pleurobranchs to somites behind VIII and IX, as well as to these somites, while the Eusicyoninæ do not develop them behind IX"

Bryozoan Fauna of the Faroes Until the present, records of Bryozoa from the Faroe Islands have been extremely few This gap in our faunistic knowledge of this region has now been filled by the publication of a hand list of the Bryozoa of these islands ("Zoology of the Faroes" Section 58 Bryozoa) compiled by P. L Kramp The list comprises 82 species all from the Faroe plateau proper—that is, within the 200 metre line and the Faroe Bank The list is followed by a brief discussion of the bryozoan fauna of the Faroes from a zoo-geographical point of view

Diagnostic Characters of Woods. In various countries now, attention is being paid to the possibility of distinguishing between the woods of different tree species with a much greater appreciation of the difficulties created by the range of diversity in structure within a species The difficulty is greater with softwoods where the structural element composing the wood is so uniform, and Mlle M Brem (*Bull Internat de l'Acad Polonaise Sci Nat*, 1934) has recently tested, on larch and spruce, the method suggested by Dr J A Stamm (*Bot Gaz*, **92**, 1931) Dr Stamm counted the number of intersections of double tracheid walls, compared with tracheid ray walls met with along a series of horizontal planes in tangential longitudinal sections of the wood The ratio thus obtained expresses the average length of a tracheid in contact with a ray compared with the total tracheid length, and ratios ranged in American trees from 0 072 to 0 288 Mlle Brem finds that, if the earliest rings on lateral branches are neglected this ratio proves a good diagnostic character to distinguish between spruce (0 1–0 2) and larch (0 2–0 3) Obviously, from the range given, this character could not safely be used alone

Petroleum Geology of Western Canada. On February 12 Mr A J Goodman read a paper before the Institution of Petroleum Technologists entitled "Notes on the Petroleum Geology of Western Canada", which includes an account of the author's conception of geological conditions obtaining in the Rocky Mountains and foothill regions respectively and of oil and gas reservoir rocks in these regions The views expressed are founded on detailed practical work and on the collected data of numerous oil wells, as is evidenced by the number of sections, sketch maps and photomicrographs included in the report Briefly, it is contended that in post-Cretaceous times the whole of the Rocky Mountains was compressed by the advent of geosynclinal strata between the Canadian Shield and the Jurasside Mountains; hence their wedge-shaped profile with flat overthrusts on the borders and steeper thrust faults within Surface structures in the foothills are predominantly imbrications in Mesozoic rocks caused by the shortening of underlying Palæozoic limestone by overthrusts Oil and gas source rocks are claimed to be primarily Palæozoic, though some may be Mesozoic The presence of oil and gas in Mesozoic strata may be ascribed to upward migration, preservation in pores and cavities and final sealing off by secondary calcite and silica, it may be attributed in part to compression of Palæozoic limestone by the Mesozoic load and later, in Laramide times, by tectonic compression, these factors caused collapse of cavernous zones of Palæozoic limestone and consequent upward expulsion of oil and gas into the Mesozoic strata Throughout this process the lighter constituents were retained in such small voids as escaped collapse in the reservoir rock. This separation of lighter constituents may also have been furthered by selective adsorption of secondary silica and silicates

The Movement of Desert Sand. In a study of the movements of sand particles in a sand storm or sand cloud, Major R A Bagnold has criticised the view that the particles are kept aloft by upward components of the turbulence of the wind Discussing the physics of a desert storm in a paper in the *Geographical Journal* for April, he shows that the supporting air currents, due to eddies in the wind, are not strong enough to support the average sand grain Moreover, in open desert country where sandstorms frequently occur, the wind currents are unusually steady Major Bagnold finds the chief cause of the flying sand grain is a bouncing action. A particle of sand gains a

horizontal velocity equal to that of the wind as it is lifted off the ground. It strikes the nearest hard surface and is deflected upwards to a height determined by velocity and size. Smaller grains at rest on the ground will also be disturbed and made to splash upward into the moving air currents. The bombardment of large grains or pebbles, too heavy to be lifted by air currents, will help to move these larger grains along the surface before the wind. Furthermore, when the sand cloud reaches an area where the grains are equal in size to those in the cloud, there will be little bouncing and the grains will tend to lie on the surface. Thus, in short, sand will collect and tend to form a dune in those areas where the size of the surface grains is the same as that of the moving sand.

Lightning Photographs. The Smithsonian Institution, Washington, has accounts of two remarkable photographs of lightning taken in 1908, and now published at the suggestion of Dr. B. F. J. Schonland, of the University of Cape Town. The first was taken with a camera revolving once in two seconds. It was a very bright flash and the thunder it caused was very sharp and sudden, like the sound of a cannon. If it is assumed that the distance of the flash is 1,000 ft. which, according to Mr. Larsen, of Chicago, who observed and photographed it, is a conservative estimate, then the diameter of the flash is more than 18 ft. He describes it as a flash, between two clouds, having the appearance of a flexible tube of very large diameter, appearing instantaneously during a very heavy rainfall. The second flash photographed looks as if there were four separate rushes following one another in the path opened by the first discharge. It shows a meandering and very complicated flash. Mr. Larsen suggests that the path was a partial vacuum of low resistance, which the beaded (or striated) appearance of the flash tends to confirm. The whole flash seems to be made up of striated alternate light and dark spaces not unlike the striæ produced in a vacuum tube.

Theory of Adsorbed Films on Metals. It is well known that a sparse adsorbed layer of alkali metal atoms on a metal surface will greatly reduce the work function of the latter, and this is attributed to an electrical double layer formed by atoms which have each lost a valence electron to the underlying metal. A similar reduction of the work function is, however, obtained with a thin layer of barium, strontium or calcium on a tungsten surface; the first ionisation potentials of these elements are all higher than the work function of tungsten, and the ordinary view of the ionisation of the adsorbed atom does not apply. R. W. Gurney (*Phys. Rev.*, March 15) has examined this problem by quantum mechanics. A simplified picture shows the adsorbed atom core as a potential well separated from the potential box of the interior of the metal by a barrier. A solution of the Schrödinger equation for this system gives a set of allowed energy levels which belong jointly to the metal and the core. In practice, the $|\psi|^2$ function, corresponding to the electron density, shows a blurred energy level corresponding approximately to the ionisation potential of the adsorbed atom and filled with electrons to an extent depending on the relative positions of this level and the critical Fermi level for the metal. This model shows how an alkaline-earth atom may behave very like an alkali metal in forming a double layer. It also explains the observed variations of the strength of the double layer with the number of atoms adsorbed, and the probability of ionisation of the atoms when these are evaporated from the surface.

The Quinhydrone Electrode. The so-called quinhydrone electrode has come into extensive use since its investigation by Biilmann in 1921 and is known to be affected by salt errors, due to the change in the activity ratio of quinone and hydroquinone, the dissociation products of quinhydrone, in presence of salts. F. Hovorka and W. C. Dearing (*J. Amer. Chem. Soc.*, **57**, 446; 1935) have now carried out a systematic investigation on this matter, and their paper includes some useful practical details of the electrode. They made the comparison against a hydrogen electrode and determined the salt error for fourteen solutes at concentrations up to $2N$. A nearly linear relation between salt error and concentration of solute was found and constants to be used in the correction of pH values were derived. The salt errors were found to be additive for many mixtures, which simplifies matters, but some anomalies were found with mixtures of sulphates and hydrochloric acid. The normal electrode potential of the system quinone-hydroquinone was found to be 0·69938 at 25°, and the standard quinhydrone electrode was found to have a potential, with respect to the hydrogen electrode, of 0·69915 at 25°.

Constitution of Coal. Although it has long been known that coal results from the slow transformation of vegetation, the exact course of this change is still a matter for investigation and dispute. Much discussion has ranged round the question whether coal substance is the survivor of either or both the cellulosic or lignin constituents of the original vegetable matter. One method used for studying this question has been to subject coal—after extraction of resinous or oily matter by solvents—to a process of controlled mild oxidation, for example, with alkaline potassium permanganate. From the nature of the products, inferences could be made as to the constitution of the 'coal' substance from which they were derived. Since 1920 it has been known, following the work of Fischer and Schrader, confirmed by Francis and Wheeler, that benzene carboxylic acids were present in the oxidation products, pointing to the existence of ready formed benzene rings in the original coal. Prof. W. A. Bone and his collaborators have carried out such oxidations quantitatively so as to account for all the carbon in the raw material, and in a recent paper (*Proc. Roy. Soc.*, A, **148**, 492; 1935) they give the results for a complete range of materials, cellulose, lignin, peat, lignite, bituminous coal and anthracite. The products got from cellulose were almost entirely carbon dioxide and oxalic acid, with no benzenoid acids. In all the others benzene carboxylic acids were important constituents, representing up to 50 per cent of the original carbon in the case of anthracite. Small proportions of acetic and oxalic acids were also measured. From these results it is concluded that lignins have been the chief progenitors of coal substance, the cellulose having mainly disappeared during its formation. All the benzene carboxylic acids—except benzoic acid—have been isolated in the products, but the penta- and hexa-carboxylic acids predominate. The results also support the view that lignin has an aromatic structure, and favours some such constitution as indicated by the formulæ of Fuchs or Schrauth.

South African Archæology and Ethnology

THE recent issue of the *South African Journal of Science*, vol 31, contains several papers on archæology and ethnology read before the South African Association for the Advancement of Science at its meeting held at Port Elizabeth in July 1934 which are of more than local interest in their general bearing Unfortunately, it is not possible here to do them full justice, and little more than a brief reference must suffice to direct attention to the more outstanding

In his presidential address to Section E, Prof L F Mainhard, of the University of the Witwatersrand, dealt with the linguistic approach to South African prehistory and ethnology, and after discussing the general principles upon which study of the morphology and vocabulary of a language may assist the ethnologist and prehistorian, applied these principles to the problem of the distribution and relations of Bushman, Hottentot and Bantu in the prehistory and early history of South Africa A comparison of the Bushman and Hottentot tongues, as well as of the two click languages spoken in Central Tanganyika, points to a remote separation, long migration from north to south, followed by re encounter of the two peoples, and at the same time supports the view of the school in physical anthropology, which maintains that the anatomical difference between Bushman and Hottentot is a fiction. On the other hand, the Hottentot distribution at the time of Bantu invasion and the continued oncoming of the Bantu from the sixteenth century, when the Portuguese recorded that they were already occupying the south-east coast, is to be inferred from place-names, while the cultural relations of the two sets of people are indicated in their loan-words Loan words relating to cattle and magic, for example, support this argument

Among the archæological communications, that of Mr John Hewitt describes a number of arrow heads and barbs now in the Albany Museum, Grahamstown Of these, some were recently discovered by Mrs J B. Meaker in the neighbourhood of Thaba 'Nchu, with other microliths, generally at the edges of dongas where pot-clay remains These are pedunculate in form and of chalcedony or quartz Two tanged arrow-heads discovered by Mr H J Aitchison, also at Thaba 'Nchu, are of interest in view of the author's opinion that they lend support either to the view held by the Abbé Breuil that the tanged arrowhead is a contribution to South African culture of the northern neolithic of the proto-dynastic civilisation, or that it is a locally evolved derivation from uninfluenced Still Bay or Wilton

Canon W. G. Sharples argues against the human origin of the so-called "Victoria West Implements" in dolerite, and demonstrates the production of implement-like forms in this material by purely natural causes.

An important paper by Dr P. W Laidler deals with the archæological and geological sequence in the Transkei and Ciskei. He points out that while it is probable that the stone age cultures of South Africa were less ancient than their European parallels, the absence of Pleistocene ice ages in South Africa deprives archæologists of the assistance they afford in Europe. There is, however, evidence in the Ciskei and Transkei of archæological relationship with pluvial periods which correspond with the phases of the ice age. As a result of the demonstration of the relation of deposits and types of industries on a number of sites, it is concluded that Stellenbosch occurred in a wet period, in which terrace gravels were laid down, possibly Gunz-Mindel, Riss-Wurm, while Fauresmith, now shown to be widely distributed and not restricted to the Free State, belongs to the gravels of a decreasing rainfall, a Levallois technique being present This culture is shown to evolve from a late Stellenbosch and to pass into the Middle Stone Age, a graded series having been found on a site at Bonza Bay The excavation of a Transkeian cave produced further evidence of the course of evolution of the Middle Stone Age, showing that high-backed, parallel flaked, lance-heads with revolved flaking preceded leaf-shaped secondarily worked blades During the Middle Stone Age there was a further wet period, producing a layer of stalagmite in a cave where all rock is now dry, and possibly equating with Buhl The leaf points coincide with a dry period, while the Middle Stone Age closed with a period of seasonal rains In the late Stone Age modern dry climate supervened

In physical anthropology the skeletal structure of the Bushman naturally figures prominently A symposium of members of the Department of Anatomy, University of the Witwatersrand, took place in which the physical characters of the Bushman were subjected to examination in detail This is here reported in very full abstract, and inevitably will in future be regarded as a standard reference.

Before dealing with this communication, however, mention must be made of a report on human skeletal remains from East London, presented by Mr L H Wells, of the Department of Anatomy, University of the Witwatersrand The material was obtained by Dr P W Laidler during his excavations on East London sites, and provides the physical anthropological counterpart of the archæological results The remains fall into three groups The 'Main Series' from various sites consists of eleven individuals, mostly of recent prehistoric age, the second group, the Quigney Slunt series, belongs to the period of European occupation and the third, the Cemetery series, comprises three skulls from a Bantu cemetery dated *circa* 1800–1870 As a general result, it is said that the heterogeneous character of the material points to the fundamental importance of adequate definition of ethnic types in South Africa The presence of Bantu features in the more recent skeletons is the physical counterpart of Maingard's historical data of the infiltration of the Bush population of this area by a Bantu element, and the predominantly Bush-Boskopoid character of the Cemetery series is striking evidence of the persistence of this ancient type, despite subsequent changes in the population

The symposium on the "Skeleton of the Bush Race" consists of eight communications, each dealing with some specific investigation based on known Bush material, partly from the McGregor Memorial Museum, partly from the anthropological collection of the Department of Anatomy at the University of the Witwatersrand The points covered include the skull, mandible, dentition, shoulder girdle and upper limb, vertebral column, sacrum and lower limb So far as the detailed results here recorded may be reduced to any general principle, it is that they point to the Bush type being highly evolved, but at the same time much specialised Thus in

relation to the calvaria, it is pointed out that an examination of curvatures of the crania show that the Bushman occupies a higher evolutionary place than Cro-Magnon man, and according to one method of study even a higher rung than the European This latter result, however, is due to the employment of a method which as a measure of foetalisation points to an extreme specialisation rather than a high status in evolutionary development In the examination of the pelvis, by Miss Margaret Orford, the results point to the similar indication of specialisation She concludes that the Bush pelvis is primitive or ape-like in many respects; and on the whole the Bush female pelvis exhibits primitive characteristics in more exaggerated form than does the male The bones are small in absolute measurement, but massive in proportion to their size The sex differences are well-marked The Bush pelvis was capable of developing secondary specialisations, such as the exaggerated features of sexual differentiation, the shallow acetabulum, etc It is, therefore, an intimate admixture of primitive and specialised features

Systems of Economic Reform

DURING recent years, men in all walks of life have begun to question the present structure of society with its apparently inevitable liability to periodic maladjustments, and in an endeavour to suggest a remedy of present ills, all kinds of proposals have been put forward The very multiplicity of these plans for economic betterment, however, is bewildering and confusing, even to those who have the time to examine them in some detail For this reason alone the recent publication by the Engineers' Study Group on Economics of a chart analysing in convenient form the salient features of fourteen different proposals for economic reform should serve a useful purpose In addition to this chart, the Group, which was formed by a number of engineers and men of science somewhat more than a year ago, has recently prepared a valuable interim report* which examines twenty four separate sets of proposals, analysing them under three headings, namely, (a) monetary, (b) industrial planning and (c) a combination of industrial planning and monetary The real division of opinion which this classification is intended to emphasise is that existing between those who think that prosperity can be reached by alterations, radical or otherwise, in the monetary system, and those who believe that some control of industrial production is required The division is also of importance in respect of immediate practical possibilities Few if any of the monetary proposals would require elaborate preliminaries, and most of them could be brought into full operation in a comparatively short time It is otherwise with the schemes which involve planning, as these would almost invariably take time to put into practice

Most of those who make proposals for economic reforms start with an analysis of the present situation, and there is a considerable difference of opinion as to the main causes of the position, though there is a measure of agreement among certain groups of schemes Several of the proposals for monetary reform definitely assert that insufficient purchasing power is at present distributed to purchase the goods which are being produced. The supporters of the Consumer Money League and of the Social Credit Scheme of Major Douglas assert that this deficiency is automatic and inevitable, accordingly the Consumer Money League advocates local note issues, while the Douglas proposals suggest remedying the deficiency either by issuing credit to retailers conditionally on sales at regulated prices, or by way of a 'national dividend' to every individual

In the opinion of Mr J M Keynes, the deficiency of purchasing power is not necessarily permanent, and his immediate remedy for the present situation is large scale public works, financed by Government loans The London Chamber of Commerce suggests the monetisation of commodities by issuing currency against eligible trade bills Silvio Gesell's 'Demurrage Money' scheme, which involves the elimination of interest, and the Kearney 'True Finance' scheme also assert that there is insufficient purchasing power, but their main remedy is designed to correct this shortage by increasing the velocity of circulation rather than the amount of money

Two more schemes, those of Lord Melchett and Prof F Soddy, diagnose a shortage of effective purchasing power, but do so somewhat less definitely than is the case with the other schemes previously mentioned Lord Melchett proposes to meet the apparent shortage by monetisation of commodities and by paying off the National Debt by means of bank drafts Prof Soddy holds that the shortage is due to the fact that it is to the interest of the bankers who control the issue of money to keep it scarce, and he therefore advocates the nationalisation of the issue of currency and credit and the control of such issues by a scientifically determined price index

The three remaining monetary schemes examined in the report, namely, those of McGregor, Deane and Sir Basil Blackett, stress lack of balance as being mainly responsible for the present situation The McGregor plan defines balance as that between spending and saving, and holds that the existing situation is due to over saving and that it can be rectified by raising or lowering the general salary and wage level by carefully calculated percentages The Deane plan, which is American in origin, stresses mal distribution of purchasing power resulting from technological unemployment as the root of the trouble and accordingly proposes a special kind of unemployment insurance Sir Basil Blackett suggests, in his "Planned Money", that the lack of balance is more general and requires to be remedied by a currency based on a price index and managed with the view of maintaining stable prices He also commends planning and co-ordination

The next group of schemes arraigns unco-ordinated individualism as largely responsible for the present troubles The schemes can conveniently be analysed into two sections, namely ·

(a) Mr Harold Macmillan's "Reconstruction" proposal, Fascism, the 'New Deal' in the United States, and the schemes of the 'New Britain' Group and of the 'Political and Economic Planning' Group.

(b) H S Jevons's 'Credit Income System', Communism, Technocracy, the programmes of the Labour

* The British Science Guild Engineers' Study Group on Economics First Interim Report on Schemes and Proposals for Economic and Social Reforms Pp 44 (London British Science Guild, 6 John Street, Adelphi, W C 2, Engineers' Study Group on Economics, Hazlitt House, Chancery Lane, W C 1 1935) 1s

Party and of the Socialist League and the scheme propounded by Edward Bellamy in "Looking Backwards" (published 1865)

Each of the schemes in section (*a*) proposes a planned and co-ordinated economic system, but none of them, except that of the 'New Britain' group, involves a departure from the basis of private enterprise Planning and co ordination are also part of the Conservative and Liberal proposals, but for them the main source of our troubles is to be found in the international sphere Both recognise, however, that the international situation is not capable of direct control, and therefore planning in some degree becomes a necessary national policy Mr Harold Macmillan proposes a compromise between the individualist and collectivist lines of thought A Central Economic Council would aim at maintaining equilibrium between supply and demand by expanding demand, remembering that the worker is also a consumer Labour would be represented on this Council, and while interference by workers in the daily management of industry is rejected, the industrial system would be humanised and opportunities for speculative profits much reduced

The six schemes in section (*b*), while they stress the failure of unco ordinated individualism, are sharply distinguished from those in section (*a*) by their emphatic assertion that the underlying causes of our present economic troubles are the 'profit motive' and private ownership of the means of production They regard a shortage and maldistribution of purchasing power as inevitable so long as these continue, and they therefore propose that the community should take over the ownership, if not the operation, of all production

University and Educational Intelligence

CAMBRIDGE —The Adams Prize for 1933–34 has been awarded to Dr Sydney Goldstein, former fellow of St John's College Dr L Rosenhead, St John's College, is highly commended for his essay The prize is awarded every two years for an essay on some branch of pure mathematics, astronomy, or other branch of natural philosophy The Sheepshanks Exhibition for astronomy, valued at about £40 for three years, has been awarded to S W Shivershwarkar, scholar of Sidney Sussex College The successful candidate is required by statute governing the award to become a member of Trinity College

An appointment to a Busk studentship in aeronautics will be made in July The studentship, worth £150, is tenable for one year, during which period the holder will be expected to devote his whole time to research Forms of application may be obtained before June 8 from Prof B Melvill Jones, Engineering Laboratory, Cambridge.

LONDON —The following appointments have recently been made Dr C H Lobban, since 1926 University reader in civil engineering at King's College, to be professor of civil engineering, King's College, from October 1, 1935 ; Dr A St G J McC Huggett, since 1931 reader in pharmacology and member of the physiology staff in the University of Leeds, to be professor of physiology, St Mary's Hospital Medical School, from October 1 ; Mr J P Ross, since 1931 University reader in surgery at St Bartholomew's Hospital Medical College, to be professor of surgery, St Bartholomew's Hospital Medical College, from October 1 , Dr H A Moss, since 1928 director of the Tyneside Council of Social Service, to be reader in sociology, Bedford College, from October 1

The title of professor of political economy in the University has been conferred on Mr N F Hall, in respect of the post held by him at University College

OXFORD The scientific contributions of early members of the Queen's College formed the subject of Dr R T Gunther's lecture last week, with especial reference to the work of Edmond Halley and Thomas Pennant who to a very large extent have the credit for having secured the publication of Newton's "Principia" and Gilbert White's "Natural History of Selborne" Sir John Floyer, the inventor of the pulse watch and advocate of cold bathing, was also a member of the College

COMMONWEALTH Fund Fellowships tenable by British graduates in American Universities for two years beginning September 1935, have recently been awarded to the following, among others Dr F X Aylward (Liverpool) to Johns Hopkins University, in biochemistry , Miss M E Francis (Girton College, Cambridge) to the University of California, in geography, A R Gemmell (Glasgow) to Rutgers University, in plant pathology , Dr Ronald Grant (Queen Mary College, London, and Universities of Edinburgh and Leeds) to the University of Chicago, in zoology , J G. M Hamilton (Edinburgh) to Harvard University, in medicine , W R Hawthorne (Trinity College, Cambridge) to the Massachusetts Institute of Technology, in engineering , Miss G G Leybourne (University College, Cardiff) to the University of Chicago, in statistics , F V Price (New College, Oxford) to Princeton University, in physics , M H L Pryce (Trinity College, Cambridge) to the Institute for Advanced Study, in mathematics , G D Rochester (Armstrong College, Newcastle) to the University of California, in physics , E D Tagg (Claire College, Cambridge) to Princeton University, in mathematics , Harold Walke (University College, Exeter) to the University of California, in physics , Kenneth White (Queen's College, Oxford) to the University of Chicago, in economics , John Wilkinson (Armstrong College, Newcastle) to Harvard University, in botany , R B Williams (Corpus Christi College, and New College, Oxford) to Princeton University, in chemistry , Leslie Young (Imperial College of Science and Technology and University College, London) to Washington University, in biochemistry R B Bryce (Toronto and St John's College, Cambridge) has been awarded a British Dominions fellowship to Harvard University, in economics The following have been appointed to fellowships tenable by candidates holding appointments in Government service overseas W E Cohen (Western Australia, and Council for Scientific and Industrial Research, Australia) to the University of Wisconsin, in wood chemistry , H C Forster (Melbourne, and the Department of Agriculture, Victoria) to Iowa State College, in agriculture , J G Gibbs (New Zealand, and the Department of Agriculture, New Zealand) to the University of Minnesota, in agriculture , H. J. N Hodgson (Melbourne, and the Engineering and Water Supply Department, South Australia) to Harvard University, in engineering , C C Wessels (Pretoria, and the Department of Agriculture, South Africa), in veterinary science

Science News a Century Ago

Ascension Island

Ascension Island, which has the smallest population of any British Dominion, was taken over in October 1815. Twenty years later, at a meeting of the Royal Geographical Society on May 25, Joseph Sabine read an account of the island written by Mrs. Colonel Power. Ascension was of interest, Mrs. Power said, for the examples which it furnished of changes wrought, even in climate, by very recent cultivation. A few years previously, it was a bare and barren cinder rising out of the waters, yielding nothing to voyagers except turtle and a very little fresh water painfully collected when required, from one or two dropping springs. When Bonaparte, however, was confined at St. Helena, it was occupied by way of precaution by a party of marines, and had so rapidly improved under their charge, and been found so healthy, and otherwise so convenient for the refreshment of ships either passing to India or attached to the African station, that it was permanently occupied, and a most interesting study it appeared to afford to the physical geographer. It was Capt. Bate, of the Royal Marines, who provided a proper water supply. He sunk a well in a ravine on the north side of the island. The spring yielded 50 tons a day and the water was conveyed to the anchorage, the pipes in one place being taken through a tunnel 1,000 ft. in length. The charge for water for strangers was 5s. a ton if delivered in Government boats or 3s. if carried off in the vessels' own boats. There was never less than 1,500 tons in the great tank on the beach. Mrs. Power gave particulars of the plants which had been introduced, and said that rain had become more frequent while there was little doubt that, in time, the whole island would be cultivated, and Ascension, from a barren rock, would be made to resemble the Azores, Madeira and other Atlantic islands.

Murchison on the Geology of Shropshire

Murchison, in some of his memoirs to the Geological Society, pointed out the existence of certain bedded trap rocks, interstratified with transition deposits, and of other intrusive trap rocks which have been afterwards injected amid these stratified masses, and on May 27, 1835, he read a paper to the Society entitled "On Certain Lines of Elevation and Dislocation of the New Red Sandstone of North Salop and Staffordshire, with an Account of Trap Dykes in that Formation at Acton Reynolds near Shrewsbury". The Breiddin Hills, he said, afford examples of both classes of trap rock, and the conclusions to which he had come were: (1) Certain trap rocks were evolved during the formation of the transition rocks; (2) others burst forth after the consolidation of these older strata, throwing them into vertical and broken forms and producing metalliferous veins in them; (3) this period of activity was anterior to the formation of the Coal Measures, as is proved by the strata of the latter resting unconformably upon the highly inclined edges of the transition rocks; (4) igneous agency evolving precisely similar products was renewed at a much later period upon one of these lines of ancient eruption; and (5) the great disruptions around the flanks of the central coalfields of England took place after the accumulation of the New Red Sandstone.

Fulton's Grand Orrery

In its column of "Weekly Gossip on Literature and Art", the *Athenæum* of May 30, 1835, said: "Another Exhibition, worthy of notice, is Fulton's grand Orrery, now to be seen in Bond Street, one of the most ingenious specimens of mechanical contrivances that has yet been exhibited. The planets and their moons revolve in their true relative periods, the inclination and eccentricity of the planetary orbits are shown with great accuracy, and from half an hour's inspection of this beautiful machine, a person unacquainted with mathematics may form a very good notion of the principal phenomena of the solar system. The proprietor has made every part of the mechanism with his own hand, and he cheerfully explains all the movements, thus rendering the Exhibition as useful to the mechanist as it is delightful to the astronomical student."

Societies and Academies

PARIS

Academy of Sciences, April 8 (*C.R.*, 200, 1257–1372). PAUL LANGEVIN and JACQUES SOLOMON: The laws of the disengagement of electricity by torsion in piezo electric substances. The general theory of piezo electricity developed twenty-five years ago by W. Voigt is capable of predicting the phenomenon of stropho-electricity, recently described by Tawil and by Ny Tsi-Zo and Tsien Ling-Chao. The formulæ obtained from Voigt's theory, although differing from those suggested by Tawil and by Ny Tsi-Zo and Tsien Ling Chao, are in good agreement with their experimental results. RICHARD FOSSE, PAUL EMILE THOMAS and PAUL DE GRAEVE: The action of hydrazine on the cyclic ureides (parabanic acid). GEORGES DARMOIS: The laws of probability with exhaustive estimation. P. VINCENSINI: Ribacour's transformation of Guichard surfaces. A new aspect of Eisenhart's transformation. SERGE ROSSINSKI: The deformation of surfaces with persistent conjugated network. Industrial Recruitment and Unemployment Problems

NO passage in the King's speech on the evening of May 6 won more cordial approval than his reference to the unemployed. In the midst of the rejoicings and demonstrations of loyalty, at a time when the industrial population of Great Britain was never so large, his words reminded all that there are still more than two million unemployed The King's wish and appeal to find them work takes us to the central problem. The development of minor interests, the provision of occupations for occupation's sake, even the provision of allotments, may do much to bring them hope and a sense of fellowship with the community It does not touch the real need Only as they find work and recover an established place in the scheme of things can they regain their independence and true estate of manhood or womanhood

To that task, scientific workers cannot be indifferent. Both rightly and wrongly, science has been blamed for much of the human wastage which has come from the rapid application of scientific knowledge in industry and elsewhere. Scientific workers have their own contribution to make in the concentration of purpose and concerted endeavour which will remove the reproach of chronic, hopeless unemployment from our land, and happily they are increasingly displaying their sense of this responsibility

Despite the attention which has been focused upon this problem in recent years, there is still no definite answer to the question how we are to find work for the unemployed on the scale required. The magnitude of the problem is well defined and the interpretation of the statistics of unemployment has been ably discussed before the Royal Statistical Society by Mr J A Dale It is clear, moreover, that no revival of trade such as may be looked for with any reasonable confidence offers the prospect of absorbing more than a fraction of the numbers concerned

It is also more widely realised that the problem of unemployment needs to be considered as a whole, and a policy developed which takes into account all the relevant and definitely ascertained facts. Attacks on the problem piecemeal, even on such special aspects as that of juvenile unemployment, can never yield adequate results and may indeed place obstacles in the way of the more far-reaching measures which the consideration of

the whole problem would suggest Two reports, entitled "The Entrance to Industry" and "The Exit from Industry", which have been issued by P E P *, commend themselves particularly to the scientific worker for this reason They are concerned with the social and individual, rather than the purely industrial aspects of unemployment, and make a noteworthy attempt to deal with the problem as a whole They bring discussion to a concrete point and set forth facts and figures which must be accepted or refuted

Both reports have as their background the conception of social security—the continued development on lines the soundness of which has been demonstrated by the severe tests of recent years of those measures of social insurance which should guarantee that no one shall starve or be ignorant or suffer ill-health, merely because he is poor or destitute They direct attention to points of friction and danger which still exist in the wage-earner's life and to their effects on the question of unemployment as a whole

In the first place, both reports demonstrate that the task is not simply to find or create an additional two million or more paid jobs of some sort Increasing employment cannot be of much help unless we simultaneously maintain and if possible raise the quality of employment That means not only increased earnings but also an enhanced status for labour, shorter working hours, holidays with pay, welfare work, provision for retirement in old age

It must also be recognised that all employment has not the same social value The employment of a man in middle life who may be the head of a family, for example, is socially more important than the employment of a young person or of an elderly person, even when all regard is had to the much more serious effects of continued unemployment on the young

These two reports are accordingly based on the principle that any adequate employment policy must not only raise the status and standards of labour but also concentrate employment primarily upon those for whom it is economically most necessary and socially most desirable—that is to say, upon able-bodied men in the prime of life, most of whom are or should be supporting wives and young families The proposals advanced are thus not to be regarded simply as schemes for raising the school-leaving age, for day continuation schools, for retirement pensions and so forth, but as carefully considered and immediately practicable sections of a new social and economic structure in which the gains of individual enterprise and self-reliance will be preserved, while the insecurity which undermines peace of mind and co-operation, together with the exploitation of boys and girls by their parents and employers at the expense of their futures and of the national good, will be smoothly and permanently eliminated

It is from this point of view that the first report directs attention to the conspicuous gap in our social services in the provision for boys and girls between fourteen and eighteen years of age Between these ages, boys and girls pass through a vital phase in development Important changes take place in their physical and psychological make-up, and their adult character begins to emerge The importance of these years has been largely overlooked both by industrialists and by the community as a whole In the absence of a carefully planned recruitment policy in particular industries, scientific vocational guidance is extremely difficult, and misfits, blind alley work and eventual unemployment often cannot be avoided Although at the moment the number of school leavers is increasing, within the next forty years the age group fourteen to eighteen is expected to decrease considerably and to represent a much smaller proportion of the total population Its economic and social value will correspondingly increase, and the elimination of waste and frustration as well as the raising of its quality by more careful preparation for industry, citizenship and leisure becomes correspondingly even more important

Such considerations endorse the policy already suggested when the problem is viewed against the background of adult unemployment The report accordingly advocates a definite policy for this age group to extend educational influences over the whole period, to ensure that the health of boys and girls is supervised effectively up to the age of eighteen and to introduce an organised system of industrial recruitment, training and welfare supervision As concrete proposals it recommends raising the school-leaving age to fifteen years and smoothing the transition from

* "The Entrance to Industry a Survey of Points of Contact between Education and Industry in Great Britain, together with Proposals for raising the School Leaving Age and for Part Time Continued Education until 18, presented as a Contribution towards a New Employment Policy by P E P (Political and Economic Planning)" Pp 56 1s "The Exit from Industry a Survey of the Provision for Old Age and for Retirement from Gain Occupation in the United Kingdom, together with Proposals for a National Retirement Pensions Scheme, presented as a Contribution towards a New Employment Policy by P E P (Political and Economic Planning)" Pp. 52. 1s (P E P, 16 Queen Anne's Gate, S W 1, 1935)

tutelage to self-dependence by introducing compulsory half-time attendance at day continuation schools up to the age of eighteen. It is estimated that these proposals would eliminate most unemployment among boys and girls and create opportunities for the absorption of about half a million unemployed men and women over eighteen by 1940, at a net cost of between £9 millions and £14 millions if maintenance allowances were not paid to those above fifteen years of age, and between £20 5 millions and £25 5 millions if maintenance allowances were paid at the rate of *5s* per week

The proposals of the second report are no less attractive They visualise the extension of the compulsory contributory old age pensions scheme so as to provide retirement pensions at the age of sixty-five years or later (at the option of the individual) The finance of the pensions scheme is simplified by sharing the cost between the State, the employer and the worker There would be savings on unemployment benefit and assistance, etc., and taking these into account it is estimated that the net cost of the scheme at the outset would be between £20 6 millions and £22 8 millions a year Under the scheme, some 620,000 persons already retired would receive a retiring pension, and rather more than 470,000 persons still in employment would be afforded an opportunity of retiring on a pension sufficient for minimum needs, and it is estimated that at least 100,000-160,000 younger workers would in consequence be absorbed.

The case for these proposals rests, however, as much on their indirect effects as on their effect on those immediately concerned. By reducing the risk of unemployment in adult life and removing entirely the fear of destitution and dependence in old age, it alleviates two of the major causes of friction in the wage-earner's life The increased social security cannot but have a beneficial effect on the general welfare and health of the industrial population, and the steadying stimulating influence on the home market should tend to increase purchasing power, in keeping with the proved experience during the world depression of those countries which have highly developed social insurance as against those that have not

The reports submit a strong case which is all the more impressive in that they visualise the employment situation as a whole. Put in another way, they suggest ways and means by which the large increase of leisure made possible by mechanisation may be regulated so that it does not take the injurious form of unemployment. To defer the age of entry into industry and to facilitate the honourable retirement in later years is obviously only a partial cure None the less, if the estimates of the reports are approximately correct, the reduction of adult unemployment by some 600,000 persons offers a large contribution to the elimination of that hard core of unemployment, constituting about a million who are out of work for long periods, many of them wholly and permanently The exact details of the schemes now produced matter less than the broad lines of the policy of concentrating employment where it is socially most desirable and providing specially for certain categories of people so as to take them out of the industrial field without hardship and indeed with advantage to themselves The great merit of the reports is that they represent a scientific analysis of the situation upon which an alert, constructive and critical public opinion can be built up, not the least important element in which is that of scientific workers themselves

Reviews

Respiration

Respiration. By Prof. J. S. Haldane and J G Priestley. New edition Pp xiii+493+17 plates (Oxford: Clarendon Press, London: Oxford University Press, 1935.) 30*s* net.

AS is implied in the title page, the present volume is a new edition of a former work, namely, "Respiration", by Prof. J. S. Haldane, published by the Yale University Press. Even in the title page, there are quite a number of changes as between the present work and the former one At the outset, the Clarendon Press is to be congratulated upon the production of an attractive volume, and the original author is to be congratulated on having secured the help of Dr. Priestley. Nor must it be forgotten that Priestley's collaboration in authorship has a particular appropriateness, for Priestley was Haldane's helpmate in the particular research which in one sense formed the climax of Haldane's work, the discovery of a simple method for the

analysis of alveolar air and the consequent investigation of the effect of carbonic acid on respiration

I have used the word "climax" above, but I am not sure that it is the right word: to ascend a summit, from the top of which new and unexplored territories stretch out— Is that reaching a "climax"? Never mind: the book reduced to its simplest terms is the account of the ascent of that summit and the subsequent exploration of the promised land which revealed itself from the top. That, as I say, is the book reduced to its simplest terms; but it cannot be reduced to very simple terms. In writing a novel, it is possible to work the subsidiary love affairs of the subsidiary characters into the whole theme, because the author has a perfectly free hand. But with Prof. Haldane it is otherwise; he has for most of his life been in some sense a public servant— a gas referee or an expert called in by this or that Government Department. The themes at which he has worked have often been thrust upon him by some public urgency, and necessarily appear as somewhat detached issues in the book. Their unity with the whole is to be found less in the subjects themselves than in the treatment of them all by the same master mind.

In a new edition, it is natural to seek for the fresh material that has been grafted on to its predecessor. In this connexion the reader will be much interested in Chapter iv, in which he will find Prof. Haldane's views on osmotic pressure set out in an attractive way. The cleavage between the present author and previously unchallenged views is expressed in the following sentence: "It was shown quite clearly by Haldane, that van 't Hoff's conception of osmotic pressure was mistaken. It is neither the concentration per litre of the solute molecules, nor that of the solvent molecules which determines osmosis, but the diffusion pressure of the solvent. Water passes through a semi-permeable membrane into a solution because the diffusion pressure of pure water is greater than that of the diluted water in the solution. The osmotic pressure is not the excess of the diffusion pressure outside the solution, but the external mechanical pressure required to equalise the two diffusion pressures."

Another very important chapter, most of the material in which is new, is Chapter xiii entitled "Air of Abnormal Composition". It treats of such subjects as the town air, that of occupied rooms, the discomforts of warm and cold air, escapes of gas, mine air containing various impurities including dust, the air of sewers and ships and of tunnels. In this chapter will be found much of the lore which Haldane has accumulated during his investigations into such matters as the safety of the Mersey Tunnel or miner's phthisis.

It is not to be thought, however, that these chapters are the only important additions; the whole book has been brought up to date, and should be on the shelf of anyone who seeks up-to-date information on almost any matter connected with respiration. J. B.

Arts of West Africa

Arts of West Africa (Excluding Music). Edited by Michael E. Sadler. (Published for the International Institute of African Languages and Cultures.) Pp. xi+101+32 plates. (London: Oxford University Press, 1935.) 5s. net.

RECENT exhibitions of the art of Indian, Chinese, African and 'primitive' peoples, such as that of the Burlington Fine Arts Club (see p. 927), have afforded the British public an opportunity of judging at first hand the merits of non-European achievement in this field. The exhibits were, no doubt, to many something of a surprise. The exhibition of African art was supplemented by the simultaneous publication of "Arts of West Africa", which enables those who are not acquainted with the literature dealing with African art, by now becoming extensive, though of unequal value, to taste the quality of this exotic production at their leisure. It had, however, a more serious purpose. Its publication was suggested in the course of discussions of the Committee on Education of the Colonial Office and was intended to vindicate African art, as something more than a 'bush' product, in the eyes of those who are interested in the West African and more especially those, administrators and others, who are in a position to influence the course of his future development.

The volume is by several hands. The most substantial contribution is by the editor, Sir Michael Sadler, who writes on "The Significance and Vitality of African Art" and is also responsible for the bibliography. Sir William Rothenstein has written a foreword, and the educational aspects of African art are considered by Mr. G. A. Stevens, formerly head of the Art Department of Achimota College, Gold Coast Colony, and Mr. Gabriel Pippet, also a member of the staff of that institution, who describes his methods of utilising the services of a native craftsman in teaching wood-carving. The principal feature of the book, however, is the thirty-two plates with descriptive notes of each object figured by Mr. Richard Carline.

The examples of African art here shown are sculptured human figures and masks, all in wood, with one exception, which is of pottery, decorated bowls of wood or pottery, and musical instruments,

utensils, stools, etc., of wood, metal or gourd, all showing characteristic employment of art motifs for decorative effect.

The area from which the examples shown are drawn is almost exclusively British territory, although, as Sir Michael points out, the whole of West Africa forms a single artistic province, including indeed differentiated local schools, but to be distinguished as a whole from the rest of Africa. The virtual restriction to British West Africa has excluded some of the most striking and æsthetically notable of the sculptures; but the examples given here are so far typical as to afford ample evidence by which to test the high estimate of the merits of African art formed by European critics. They will also enable those open to conviction to appreciate it as something more than merely grotesque and bizarre and as worthy of serious study as an expression of a real and strong emotional reaction to reality, in forms which may be denominated 'art' in the more conventional sense of that term.

It is precisely here that difficulty arises in any attempt to develop the artistic genius of the African along lines in harmony with his bent as exhibited in this tradition. African art, as known in the examples which have attained the high standard of æsthetic appreciation, belongs to the past. It is the product of a pagan environment, a product of a religious and ethical background which has now passed, or is passing, before the onset of white civilisation and the Christian religion. Surprise has been expressed that the anthropologist collecting examples of African art as ethnographical specimens should have chosen those which almost universally were æsthetically right, according to the standards of the critics. The explanation is that to the anthropologist this is no primitive art, as it is conventionally regarded, but an art which is the product of a long course of cultural development, in which emotional expression, technique and cultural environment generally have attained a certain state of equilibrium, susceptible of definition. His choice has fallen advisedly, therefore, on those specimens which seem most perfectly to exemplify that equilibrium and to display most completely the ethos of the people, their 'soul', as well as their highest and most characteristic technical accomplishment. In African art it combines a religious or magical symbolism, expressed through representation of natural forms, with a disposition of mass and line which displays a remarkable feeling for pattern, but is conditioned by the technique of the knife. The importance of this technique in the production of characteristic forms is indicated by Mr. Pippet's experiment in employing a native demonstrator for teaching wood-carving.

In so far as the aim is representation, African art is crude and imperfect, whatever may be its unconscious success as abstract art. The anthropologist who regards these matters, not from the point of view of abstract art, but in terms of culture, and in so far as his studies have practical application with the view of cultural development, may well question, now that the state of equilibrium has been disturbed, whether the elimination of crudities and imperfections of technique, as well as the suppression or transformation of the central emotional inspiration, may not also eliminate the artistic feeling for pattern and design. More often than not, in European children, the process of perfecting eradicates the capacity to charm found in the *naïveté* of their early efforts, to which Sir William Rothenstein compares the appeal of African art.

A Base-Less Fabric

The Natural Logarithm. By Sir Charles Vernon Boys. Pp. 31. (London: Wightman and Co., Ltd., 1935.) 2*s*.

NO practical man ever saw the least difficulty either in the idea of logarithms to a given base or in the use of common logarithms in arithmetical work. But if the practical man becomes inquisitive as to the methods by which his tables have been computed for him, or if he has to learn the use of logarithms in integration, the mathematician takes him seriously in hand; a quarter of a century ago, he was plunged into uncongenial algebraical analysis, into which the mysterious e was introduced dogmatically; nowadays, he is more likely to be told that the logarithm is defined as an integral, and to be set the bewildering task of pretending that he has never used a logarithm in his life. Sir Charles Boys, in his younger days, met with the first fate, and for a long time the natural logarithm seemed to him utterly artificial. Now he has found a direct line of approach, and he has written a tract which he tells us he would have swallowed whole if it could have been given to him when he was trying to digest Todhunter's account of the exponential series.

The interesting fact is that Sir Charles Boys has really turned, like the pure mathematicians, to the integral: his central investigation concerns the area under an arc of the rectangular hyperbola $y = 1/x$. But there is a difference. Having found, by a simple geometrical argument, that the area under an arc depends only on the ratio of the abscissæ of the end-points, the practical man is satisfied to recognise that the areas *are* logarithms, to some base or other. He finds that he can

calculate these logarithms, and the value of the base does not interest him patently, the values of these logarithms are what he wants in integration, while if he wants logarithms to base 10 he has only to divide his areal logarithms all by the same constant, namely, the areal logarithm of 10 itself

The crucial stage then is to devise a process of calculation. Sir Charles Boys gives Archimedes' quadrature of the parabola, and replaces the hyperbolic arc by an arc of a parabola He shows that even the simple choice of the parabola which touches the hyperbola at the two end-points of the arc gives an approximate logarithm accurate to 1 in 10^7 if the argument is between 1 0 and 1 1 This parabola lies inside the hyperbola, and the approximation is necessarily in excess An obvious modification is to introduce a parabola which crosses the hyperbola and allows some compensation of errors, and Sir Charles makes an ingenious choice which, without adding substantially to the arithmetic, reduces the error from 1 in 10^7 to 1 in 10^{11}

The weakness of the presentation is that both to determine the best parabola and to estimate the error Sir Charles uses the classical logarithmic series If, after all, we are dependent on this series, the work becomes on the arithmetical side a mere curiosity The classical series, as the author shows—though not in the language a mathematician would use—follows at once from the identification of the logarithm with the area, and since obviously the series *could* be used for calculation, the question whether the existing tables were actually calculated as efficiently as they might have been is of no practical importance The practical man does not want to recalculate logarithms of any kind, but he does want to understand the natural logarithm, and this tract will show him very clearly how natural it is On p. 22, H^s and A^s should be H_s and A_s.

Scientific Study of Dust

Dust. By Dr S Cyril Blacktin Pp. xi+296+2 plates. (London Chapman and Hall, Ltd, 1934) 18*s*. net

DR. BLACKTIN has written a book which is a mixture of philosophy and fact In modern days this is unusual in a scientific textbook, and initially makes rather interesting reading. The scientific reader in search of a lucid exposition of dusts and smokes, however, will find it rather difficult to differentiate between the facts and Dr. Blacktin's own philosophy. The author has considered every conceivable aspect of smokes and dusts, even explaining how they help in the scientific detection of crime (Under the heading of dusts he includes such widely diverse systems as sandstorms, volcanic eruptions and ice particles)

One is left with the impression after reading the book, however, that Dr Blacktin would have done well to have specialised more on the scientific and technological applications of the subject, rather than to have dwelt on a large number of extraordinarily interesting and out of the way facts, which are somewhat irrelevant to the scientific investigation of atmospheric pollution or its allied problems

The author has also introduced a new nomenclature, and a new set of definitions which, as the old ones of Gibbs (depending upon size) have been in general use for some years, is to be regretted, especially as the new ones are founded more on assumption of certain properties of particles than on fact Most workers will disagree strongly with some of the definitions and statements Thus—taking only one example, for the book provides much material for polemical discussion—Dr Blacktin's definition of the difference between a smoke and a dust is that the latter is a disperse system in which the individual particles are breaking up and becoming smaller, due to a self-abrasive or disruptive approach action, whilst in the former the particulate matter is increasing in size, due to coagulation There is no doubt of course about coagulation, but almost certainly this process continues until the particles are so heavy that they fall out under gravity. All the experimental and theoretical evidence is against a change in which disintegration commences and the particles become more numerous Nor is there any evidence of an equilibrium state which would exist if Dr Blacktin's views were correct The coagulation of a smoke system, of course, becomes very slow as the particles get larger and less numerous, but this is due to the lack of Brownian diffusion and hence the small chance of collision, which also suggests the remoteness of the possibility of self-abrasive action in dusts of larger particle size.

Dr. Blacktin's book, however, will be valuable as a guide to industrial and technological workers There is no phase of the subject on which he has not touched, in industry, in physiology or in Nature He has also included an invaluable collection of almost six hundred references, and the work will be useful as a book of reference on the subject to the reader who has little or no previous knowledge of dusts One criticism the reviewer must make is that he has found the English very obscure in places , this is a very real blemish in a book of this description.

Short Notices

Scottish Folk-Lore and Folk Life: Studies in Race, Culture and Tradition. By Donald A. Mackenzie. Pp. ix+310. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1935.) 10s. 6d. net.

MR. MACKENZIE gives his readers a comprehensive view of the main heads of Scottish folk-tradition and belief. He ranges from food taboos to giants, fairies and goddesses. One of the more remarkable of the topics with which he deals is the attitude of the Scottish people towards the pig. Among the other peoples of Britain it has always been more or less a staple article of diet; but in Scotland, although there is evidence that it was eaten and was a victim in sacrifice, generally, or at least widely, it has been avoided as an article of food. Mr. Mackenzie holds that this attitude is pre-Christian, and derives it from the East, whence he thinks it may have been taken by the eastern Celts from Attis worship and the legend of the slaying of the god by a boar.

Current theories on the Celtic (or 'Keltic') question find little favour with the author, and he will not tolerate views which make Scotland dependent upon Ireland. In race and in folk lore and tradition, he argues strongly for the individuality of Scotland, which he maintains has developed on the whole with singular freedom from alien influence. On the other hand, he seeks to show that in such matters as the food taboo, already mentioned, and the belief in mother-goddesses, there is cogent evidence of a cultural diffusion from the East. Mr. Mackenzie might have been more convincing had his treatment been more systematic, and loose statements and slips less frequent. "Alpine" and "Armenoid", for example, as racial terms are not interchangeable. La Tène is not "early" Iron Age and "the late Mr. Gray" could not have measured 5,000 recruits during the War, as, to the regret of his friends, he died two years before it began.

New Light on Old Masters. By Prof. A. P. Laurie. Pp. 163+12 plates. (London: The Sheldon Press; New York: The Macmillan Co., 1935.) 6s. net.

IN this book, miraculously compressed to a modest 163 pages, is summarised that fund of information on the painter's methods and materials so authoritatively expounded in Prof. Laurie's earlier volumes. To effect this sweeping condensation, without sacrificing the scientific and historical approach, must have been extraordinarily difficult; but Prof. Laurie, by pursuing the substance rather than the form, has contrived not only to retain practically every significant fact from his earlier works, but also to introduce many new ones. Obviously, he has made certain unwilling sacrifices of style and spaciousness: occasionally, an argument has been so condensed as to lead perilously near to a brilliant *non sequitur*. But his matter is intensely interesting.

A concise opening survey of the development of the palette precedes a description of Italian quattrocento painting methods, as set forth in the "Libro dell' Arte" of Cennino Cennini, and a later chapter on the Van Eyck technique is particularly good. The final section, on scientific examination of paintings—a field wherein Prof. Laurie has been a bold pioneer—is illustrated by references to actual problems encountered. One could wish that the author had underlined more heavily the present limitations of certain scientific weapons: for many who should know better tend nowadays to regard, for example, X-ray examination of any painting as an unfailing criterion of pedigree, provenance and general respectability. P. D. R.

The Neural Basis of Thought. By George G. Campion and Sir Grafton Elliot-Smith. (International Library of Psychology, Philosophy and Scientific Method.) Pp. vi+167. (London: Kegan Paul and Co., Ltd.; New York: Harcourt, Brace and Co., 1934.) 9s. net.

THIS book takes its stand on the view that the terms which are used in thinking processes are constantly changing and developing, and in reality display none of that fixity which has sometimes been considered to be the main characteristic of the 'concept'. It is suggested that this is due to the fact that the material of thought is always being influenced by affective or emotional responses. Head and Holmes have demonstrated that in "some way the essential organs of the thalami are the centre of consciousness for the affective side of sensation". There are, as is well-known, innumerable paths of connexion between the thalami and the cortex. The authors hold that these "are return paths for reflex neural impulses from the cortex which excite relay cells in the thalami, and that these relay cells in turn send stimuli both to the essential thalamic organs and also to the same cortical areas from which the paths conveying the return impulse originated". Hence it is argued that thought processes must be pictured as based upon a constantly circulating stream of neural impulse from cortex to thalami and from thalami to cortex.

Measures and Weights. By Sir Flinders Petrie. Pp. x+22. (London: Methuen and Co., Ltd., 1934.) 2s. net.

IN this little book, Sir Flinders Petrie returns with the added experience of his excavations in southern Palestine to a subject of which he has always stressed the significance. "The study of ancient measures used in a country," he says here, "is a basis for discovering the movements of civilization between countries. The study of ancient weights serves to show the trade connections at any given period." Beyond his introductory remarks, however, Sir Flinders does not discuss the general principles, with which he has dealt elsewhere, but outlines the subject only for ready reference as to detail in the practical work of the archæologist.

Systems of Echo Sounding

THE recent revival in shipbuilding has re-awakened interest in various items of ship equipment One of the most important of these developments has taken place in the methods of sounding, and it has recently been stated, by a high authority in these matters, that no modern ship could be considered properly equipped without the fitting of echo sounding It is the purpose of this article to review briefly the principal systems at present in use, and to attempt to draw a fair comparison between them

The first suggestion that submarine depths could be measured by determining the time interval between the moment of transmission and the return of the echo, appears to have been made by Arago in 1807 In 1855, Lieut M F Maury, of the U S Navy, who devoted particular attention to navigation and meteorology, made unsuccessful experiments designed to realise the method in practice

The loss of the *Titanic* in 1912 prompted Richardson to formulate a similar suggestion in more explicit form This, together with the general growth of shipping, stimulated workers in various countries It is undoubtedly a fact that work on submarine listening during the War did much to lay the basis for the technique required to develop a genuine aid to navigation Although it is reported that Behm succeeded in measuring depths in Lake Ploen in 1912, it was not until January 1923 that the first public report made by the Director of the

FIG 1 Indicator employed with Admiralty High Frequency Gear

French Hydrographic Service showed that this new and indirect method of measurement was well adapted to practical needs This report was to the effect that a line of soundings had been run across the Mediterranean in April 1922 in connexion with a projected submarine cable In June 1922, the U.S.S. *Stewart* obtained a line of echo soundings across the Atlantic from the American coast to Gibraltar, and continued the line of soundings from Gibraltar to Port Said in July 1922. This apparatus was designed by Dr. H C Hayes, of the U S Navy Within a year or two, every important maritime country in the world had announced the completion of successful trials of echo sounding apparatus of one sort or another

FIG 2 Fathometer Indicator, Universal Type, 432

The method of initiating the pulse of a sound and receiving the echo and measuring the time interval between the two events may be considered broadly under two distinct headings —

(*A*) THE SONIC SYSTEM In this case, (1) a steel hammer strikes a steel plate in the bottom of the ship and sends out a highly damped compressional wave (This method has been used by the British Admiralty, and 'Fathometer') (2) A Fessenden, or similar oscillator, sends out a short pulse of sound at a frequency of a few thousand cycles per second (This method is also used by 'Fathometer') (3) Detonation of an explosive; for moderate depths a gun may be fired at the surface of the water, or for greater depths, the charge may be exploded beneath the surface (Behm)

(*B*) THE SUPER-SONIC SYSTEM In this system a high-frequency oscillator is employed giving a beam of sound waves up to as much as 30,000 or 40,000 cycles per second This sound wave is of such high frequency that it is inaudible to the human ear There are two principal systems which employ this method ·

(1) The Langevan-Chilowsky system. This employs a quartz mosaic between two steel plates of such thickness that the fundamental frequency of vibration is of the order of 30,000 or 40,000

cycles per second. A suitably cut quartz plate possesses the property of expanding when an electric field is applied in one direction and contracting when the field is reversed. The application of an oscillatory condenser discharge to the quartz plates produces an oscillatory mechanical movement of the steel plates. As the radiating surface is several wave-lengths in diameter, a sound-beam is produced.

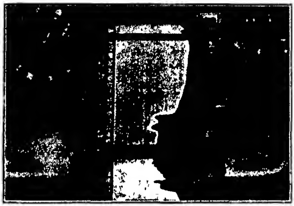

FIG. 3. Contour being drawn by 'straight line' recording gear.

(2) The British Admiralty high-frequency system. This employs a laminated structure of nickel with a resonant frequency of approximately 16,000 cycles per second. Nickel possesses the property of contracting in an increasing magnetic field and increasing in length in a diminishing field. The laminated structure constitutes a closed magnetic circuit provided with a toroidal winding, so that an oscillatory condenser discharge through the windings sets up an oscillatory magnetic field in the nickel, and produces corresponding mechanical vibrations. The vibrations are concentrated into a beam of about 45° angle.

It must not be judged from the foregoing description that all of the devices enumerated are equally well-adapted to every purpose. For example, the non-directional properties of the sonic system necessitates that the hydrophone or receiver be comparatively remote from the transmitter in order that the latter part of the transmission may not interfere with the front part of the returning wave train, especially in moderate depths of say 10 fathoms. This separation has the effect of compressing the scale at its lower end, rendering precise readings more difficult just where precision is sometimes most needed. The short wave train and the directional properties of supersonic systems both enable the transmitter and receiver to be placed close together, and under favourable conditions makes possible readings to within a foot or so of the keel, at least in the case of the Admiralty magneto-striction system.

A further advantage of the use of a supersonic frequency is that the tuned receiver is less subject to disturbance from water-noise and general ship's noises than is the case at lower frequencies.

On the other hand, low-frequency sounds are less subject to attenuation in passing through the hull of the ship and also in passing through great depths. In the case of the Langevan-Florisson system (30,000–40,000 cycles per second) it is necessary to cut a hole in the bottom of the ship and transmit through a thin diaphragm, and even then it is not considered practical to apply this system to depths greater than 750 fathoms. In contrast to this, sonic systems have been employed to sound the greatest ocean depths. The Admiralty high-frequency magneto-striction system (about 16,000 cycles per second) combines to a great extent the advantages of both sonic and supersonic systems and is employed without the necessity for cutting the ship. Depths of more than 1,000 fathoms have been sounded by this system, transmitting and receiving through a ⅝ in. thick steel hull, and the echo was then of such an intensity as to hold every promise of taking soundings in the greatest ocean depths. The following comments upon this system are made in a paper on "The Fiord Region of East Greenland", by Louise A. Boyd, published recently by the American Geographical Society:—

"This installation represented the very latest development in ultra sonic depth-measuring

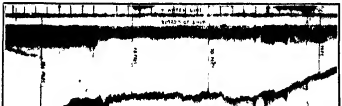

FIG. 4. Record on Admiralty "Challenger" magneto-striction recorder. Minute time scale along water line. Speed of ship, 22 knots.

technique, and the trial showed that its efficiency was greater than that of any previous apparatus of the same size and type. In the tests off the Lofoten-Vesteraalen islands not only were the desired 1800 meters obtained, but approximately 2200 metres (1200 fathoms). Reaching that depth, the ocean bottom leveled off, and the instrument

was still recording vigorously when we turned back toward shore "

The question of accurately recording the time interval between transmission and reception of a sound pulse raises difficulties of considerable magnitude, when the speed of sound in water is approximately 4,800 ft per second, this means that a depth of 400 fathoms (allowing for the double effect of the reflected sounds) corresponds

FIG 5 Shallow water record

to one echo-second In other words, on whatever scale may be selected for recording the depth, changes of one foot must be made by the recording agent in a 2400th of a second It is easy to see that to do this with precision involves immense care and thought in design

Many devices have been brought out to achieve this result The earliest method was to make a scale of feet or fathoms with the full limit of the depth required marked on it in the smallest readable markings The original scale of the British Admiralty listening gear was a circular drum 12 in in diameter, on which 130 fathoms was scaled to feet markings or half fathoms The light flashing scales of the Fathometer and Langevan gear can also be scaled to ½ fathoms

The latest form of indicator employed with the Admiralty High Frequency System is normally scaled to half fathoms, but a recent installation had a scale of 50 fathoms on which 1 foot = 0 1 in, and on this scale, a change of depth of 1 foot could easily be detected Fig 1 illustrates this instrument, which is well adapted to use on the bridge, being the 'indicator type' in which a pointer moves over a large dial with a convenient open scale, and remains steady at the depth, only moving as the slight changes of echo time impel the needle.

For navigation the echo sounder was employed originally to delineate the 100 fathom line, and it was accepted by the ships' officers in the early stages for the purpose of getting the check on position Recently, the interest taken by the shipowner has greatly enlarged its usefulness in the direction of lesser depths, with the view of preventing grounding or straining the ship when passing through channels or mouths of rivers where mud and silt have made the depth of the fairway uncertain to a few feet The demand for shallow depths has become so acute that the reading of 3 feet under the bottom will become an essential of echo sounding

The Fathometer light-flashing scale gives deep and shallow readings within coarse limits by employing two speeds for the flash as it travels round a circular dial (Fig 2), but the light-flashing method cannot be read to sufficient accuracy to ensure a ship passing over a bar within an accuracy of one foot

The best method of reading very shallow depths is by large-scale recording, and a method has been recently introduced in which 1 ft = ⅛ in This machine would enable a ship to pass over a bar within 1 foot of the bottom with absolute accuracy A 2-speed gear would enable the scale to be decreased ten times, thus enabling the gear to be used either for shallow or deep echo sounding.

RECORDING GEAR

The most effective type of recording gear up to the present time has been the British Admiralty

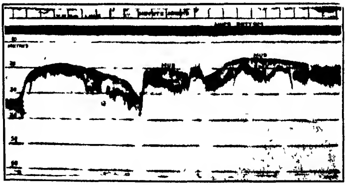

FIG 6 Record showing mud surface and under surface of rock

pattern on which the echo depth is marked by a pen moving on a straight path by means of a cam motion. The record paper is fed over a wet wick, and the echo signal marks the paper, which is impregnated with starch-iodine. This method, which can be called straight line recording, has a uniform scale and gives a true picture of the shape or contour of the bottom (Fig 3): but it must be observed that the records cannot be described as true to scale, because the rate of movement of

the ship is much greater than that of the record paper on the scale of depth For example, a ship moving at 15 knots will travel 1,500 feet per minute, and even if the record paper were fed at the rate of 3 inches per minute, the maximum width of the paper is only 5 inches for a depth of 100 fathoms or 600 feet

This compression of distance, however, is not a disadvantage, as it only tends to exaggerate the contour, and a hole or bank will be indicated with a steeper rise or fall, say, in the proportion of 3 or 5 to 1, according to the speed of the ship (Fig 4)

Fig 5 is taken from the British Admiralty pattern boat gear, which operates on precisely the same principle as the *Challenger*, but is specially adapted for shallow water It will be seen from this diagram that a very great degree of accuracy in exceedingly shallow water can be obtained

Advantages and Disadvantages of certain Types of Distortion

The desirability of avoiding the compression of the scale near the zero due to the large separation entailed by the use of some systems has already

FIG 7 Example of sounding by phasing

been mentioned. Another form of distortion is introduced by recorders of the Fathometer type, in which the stylus traverses the paper along the arc of a circle. A line of soundings obtained over a symmetrical bank produces a record on which the bank appears to be inclined toward the centre of curvature of the stylus path Soundings taken along the same line but in the opposite direction will incline the bank in the opposite direction with reference to neighbouring features on the chart. The Admiralty chemical recorder, on the other hand, due to the rectilinear path of the stylus produces a symmetrical record of a symmetrical bank, and gives a faithful record of any irregularities in the sea bottom passing along the same line in either direction Fig 6 illustrates the accuracy with which this method can detect the nature of the bottom, showing the two echoes that

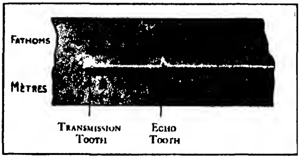

FIG 8 Scales of light flash echo-meter

can be obtained, (1) from the soft initial surface of mud, and (2) from the under surface of rock By an ingenious method of phasing, it is possible, in this instrument, to retain an open scale and at the same time read up to very considerable depths, for example, in one instrument a scale of 90 fathoms to 5 inches or 18 fathoms per inch can be retained, while by phasing, soundings up to 250 fathoms can be taken Fig 7 shows a typical example of this In studying this chart and applying the figures written on the chart, it will be seen that the sections of slope can be added on to one another to give a true representation of the formation of the bottom This is not, of course, actually necessary when the 100 fathom phase is applied

Indicators

In the combined recording and indicating bridge instrument supplied by the Submarine Signalling Company, a light travels round a dial in eclipse and flashes out at the moment the echo is received In the 'Echo-Meter' "Marconi" (Fig 8) a curved scale is employed and a flashing light is given a uniform velocity along the scale, and flashes up in a small peak at transmission and again when echo occurs Thus it is possible, as these flashes take place with great frequency, to read roughly the echo distance or depth on the scale. From the point of view of the bridge officer, the use of light for 'indicating' is open to certain objections, in the first place, on a bright day it is difficult to see, and conversely at night it is not advisable for eyes that have to look out into the darkness also to have to watch a small flashing light on the bridge. In this respect the Admiralty pattern

indicator (Fig 1) seems to have distinct advantages, where a simple pointer on a dial is employed, which is dimly illuminated at night.

Echo sounding, as an item of standard equipment, has now definitely come into being, and there is little doubt that with increased experience ships' officers will become more familiar with the technique of using this instrument As a result, an immensely increased and much more accurate knowledge of the conformation of the bottom of the sea, particularly on regular routes, will be developed; and navigators will find more and more that they can determine their position accurately by this means.

Fossils as Indicators of Continental Drift*

By SIR ARTHUR SMITH WOODWARD, F R S

STUDENTS of fossils are interested in Wegener's theory that the continents are floating on a heavier layer of the earth's crust which, sometimes at least, becomes plastic and allows them to move through different longitudes and latitudes If there has been such movement during geological time, this may clearly explain the changes of climate in many areas to which fossils bear witness It affords a possible reason for the occurrence of plants and animals of temperate or even subtropical habit among the fossils found in the present arctic and antarctic regions It also perhaps shows why the land and fresh-water life of the coal period throughout the northern hemisphere was so remarkably uniform

The use of fossils, however, in testing Wegener's theory and in determining former land connexions is not so simple as it might at first appear For example, some who have noted the remarkable similarity between the graptolites in the earlier Palæozoic rocks on the two sides of the Atlantic have concluded that western Europe and eastern North America must have been close together when these graptolites lived in a continuous shallow sea Others, who have studied also the associated life, have decided that the two areas in question were already separated in Cambrian to Silurian times by a great Atlantic Ocean in which sargasso seas sent forth both to the east and to the west the same floating organisms There are thus two equally plausible interpretations of the facts, one in favour of Wegener's idea that during the Palæozoic era the continental lands were continuous, while the other points to the immense antiquity and the permanence of at least one ocean basin

Again, the extensive and nearly uniform distribution of many of the Devonian fishes, which must have lived chiefly in fresh-water lakes and rivers, seems remarkable if the continental areas in the Devonian period were as widely separated as they are at present It must, however, be remembered that there were already other fishes in the contemporary seas, and certain sporadic fossils suggest that the normally fresh-water forms could also live in the sea, like the existing sturgeons In this case, they could spread along the coasts and attain their strangely wide distribution even if the lands were arranged approximately as they are at the present day

There is also the great difficulty, that many fossils which look superficially alike and might be regarded as nearly identical, are really parallel developments from common ancestors This has been recognised for many years by those who have studied molluscan and brachiopod shells, and it is now becoming familiar to those who investigate other groups The principle is perhaps most easily understood by reference to discoveries of fossil mammals in North America

The early Tertiary ancestors of the camels in North America were small animals shaped like gazelles with pointed hoofs According to Prof W B. Scott, they divided into two distinct groups, one adapted for browsing on shrubs and trees, the other adapted for grazing Afterwards, the toes in each of these two groups became blunt, and the characteristic cushioned foot of the modern camels was developed The camel foot therefore arose independently in at least two separate lines derived from the same stock. According to Prof. H F. Osborn and others, the Tertiary ancestors of the horses and rhinoceroses in North America also show parallel lines of evolution The gradual approach to the one-toed foot of the horses and to the horned snout of the rhinoceroses occurred in several distinct groups at the same time, though sometimes at different rates Prof. Osborn has also pointed out, in his recent great work on the Titanotheres, that these massive horned mammals, which flourished during the middle of the Tertiary era, evolved on several distinct lines, and independently acquired horns and other features which were approximately the same

Remembering these facts, it is interesting to consider some of the fossil animals which have actually been regarded as proving former connexions of some kind between lands which are now well separated.

The skeletons of certain fossil Sparassodonts

* Extended account of a contribution to the discussion on "Wegener's Hypothesis of Continental Drift" at the meeting of the Geological Society of London on January 23, 1935

found in the Lower Tertiary deposits in Patagonia are so similar to the skeleton of the marsupial Thylacine now living in Tasmania, that these animals have sometimes been referred to the same family. They have therefore been interpreted as indicating a former direct connexion between South America and the Australian region In their palate and successional teeth, however, the Sparassodonts are more nearly similar to some of the early Tertiary primitive Carnivores known as Creodonts, which lived in the northern hemisphere and might well be regarded as also the ancestors of the Australian Thylacine The Sparassodonts and the Thylacine, therefore, may be merely parallel developments from the same northern source, which migrated southwards by two different land-routes to the remote, widely-separated areas where they are now found

Among the fossils discovered in late superficial deposits in Australia and some adjacent islands, there are species of a peculiar horned tortoise, *Miolania*, which has the tail armoured with rings of bone A nearly similar tortoise, which has been referred even to the same genus by some authors, occurs in a rock of uncertain age in Chubut, Patagonia Here again, at first sight, there seems to be evidence of a former direct connexion with the Australian region and South America. *Miolania*, however, belongs to a sub-order of Chelonians which had a very wide distribution over the northern hemisphere before it became specially characteristic of southern lands The species found in Australia and South America may therefore be merely independent offshoots of the same source which have retreated south by different routes

The same explanation almost certainly applies to the little Mesosaurian reptiles which are found in the Permian rocks of South America and South Africa, and have been quoted as part of the evidence that at the end of the Palæozoic era these two lands were directly connected In the Coal Measures of both North America and Europe, which represent a somewhat earlier geological period, there are ancestors from which the Mesosaurians were possibly derived, and these reptiles may have gone south in parallel ways down the African and American continents Similarly, the Dicynodont reptiles, which occur in slightly later rocks in both countries, may have wandered southwards independently, for they are known to have been distributed at the time over Europe, Asia and North America These fossils therefore do not help to prove that South America and South Africa formed a continuous land when the reptiles in question were living, and the recent discovery of numerous large Rhynchosauria in the same rocks in southern Brazil suggests that there was no such land-connexion, because no trace of these reptiles has been found in the well-explored corresponding rocks in South Africa

It is thus evident that when former changes in land-connexions are being discussed, it is not enough merely to compare lists of fossils The precise relationships of each fossil need first to be determined so far as possible, and even if this precision can be reached, there are often alternative interpretations which have to be considered

Obituary

PROF. H B BAKER, C B E, F.R S.

THE recent death of Herbert Brereton Baker removes a familiar name from the roll of chemists who made their reputation before the opening of the present century. He was born on June 25, 1862, as the second son of the Rev John Baker, curate-in-charge at Livesey, near Blackburn—a district in which the distress arising from the cotton famine was then intense, and the relief of which was a real concern of the Baker family. After a period of schooling at Blackburn, both boys were enabled, by sacrifice and rigid economy on the part of their parents, to become pupils at Manchester Grammar School Beginning on the classical side, young Baker turned over to science, securing later a scholarship at Balliol, as well as a Brackenbury school scholarship The teaching of chemistry at the Manchester Grammar School was then in the capable hands of Francis Jones, and Baker was always ready to acknowledge his debt to one whom he termed "the best of all teachers".

Baker's tutor at Oxford was H. B Dixon, and the enthusiasm for investigation which the senior man possessed in an eminent degree was communicated to his pupil After taking a first class in natural science, Baker was appointed demonstrator at Balliol and private assistant to Dixon; an association which led him to the main investigations of his life—the effect of moisture on chemical change

In 1884 Baker was appointed chemistry master at Dulwich College, and on his initiative a science side was developed on the same lines as at Manchester The chemistry department at Dulwich had already some tradition of research, and equipment for such work had been provided by Baker's predecessor, Alfred Tribe, best known, perhaps, as a collaborator with J H Gladstone. The tradition was more than maintained by Baker, and, in spite of heavy teaching duties, he published during this period a great deal of the work with which his name is specially associated It is indeed a remarkable fact that Baker

was elected a fellow of the Royal Society in 1902, while he was still a schoolmaster

After a short period as headmaster of Alleyn's School, he returned in 1903 to Oxford, succeeding Vernon Harcourt as Dr Lee's reader at Christ Church To a man of Baker's temperament the opportunities offered by such a post were naturally more attractive than the administration of a large school, and he took a prominent part in the long overdue reorganisation of the teaching of chemistry at Oxford

In 1912, the year in which the Chemical Society awarded him the Longstaff Medal, Baker was appointed to the directorship of the Chemistry Department of the Imperial College of Science and Technology in succession to Sir Edward Thorpe, and this post he occupied until his retirement in 1932 It was not long before the placid course of academic teaching and research was rudely disturbed by the outbreak of war, and Baker was one of the first chemists called on in 1915 to deal with the serious problems of gas warfare, in this field he rendered distinguished service, taking a prominent part in devising measures of protection against poison gas, specially phosgene His work was recognised by the award of the C B E.

The War over, Baker returned to the administration of a department overflowing with students, and to the research work in which his interests mainly lay His position as one of the leaders of British chemistry was afterwards recognised by the award of the Davy Medal of the Royal Society in 1923, and by his election as president of the Chemical Society for the period 1926–28 Apart from his special scientific interests, Baker took a share in the activities of the University of London, and served for a number of years on the Senate and its committees

Baker had married in 1905 Muriel, only daughter of H J. Powell, partner in the Whitefriars Glass Works, herself a chemist and a collaborator with her husband in various researches Mrs Baker and a daughter survive him

The starting point of Baker's life-work was Dixon's observation that a spark could be passed through a mixture of dry carbon monoxide and oxygen without any explosion occurring A natural development was the study of the effect of thorough drying in other cases of combustion, and Baker was able to show that the combination of various solid elements with oxygen at a high temperature is enormously retarded, or even prevented altogether, provided stringent measures are taken to dry the apparatus and the materials The successful distillation of phosphorus in dried oxygen was a striking case in point

Following up these early observations, Baker studied the behaviour of thoroughly dried substances which ordinarily react—in some cases violently—with one another Among the remarkable results of his drying technique was the proved absence of reaction in the following cases: (*a*) sulphur trioxide and lime, (*b*) hydrogen and chlorine, (*c*) ammonia and hydrogen chloride It was further shown that the thermal dissociation normally characteristic of ammonium chloride and mercurous chloride does not occur when the substances are thoroughly dried. Subject to the same conditions, a mixture of electrolytic hydrogen and oxygen can be heated to a high temperature without explosion or even partial combination

Many workers have attempted in vain to repeat these classical experiments Baker showed, for example, that ammonia gas, previously dried by pure quicklime, could be finally desiccated over carefully purified phosphorus pentoxide without any appreciable absorption of the gas by the pentoxide This has been frequently challenged, but it is now clear that he was entirely in the right, and that few have succeeded in reproducing his technique.

The earlier work on ammonium chloride and mercurous chloride led Baker, in collaboration with his wife, to examine the case of nitrogen trioxide As hitherto prepared, this substance invariably dissociated on evaporation, but it was now shown that the thoroughly dried liquid could be vaporised without decomposition The incidental observation that nitrogen trioxide had an abnormally high boiling point initiated an investigation into the influence of intensive drying on the physical properties of liquids generally, and in various papers and addresses to the Chemical Society between 1922 and 1929, Baker described determinations made of the boiling point, surface tension, vapour density, etc, of intensively dried liquids. many of these substances had been desiccated with phosphorus pentoxide over the War period Intensively dried benzene, for example, was found to boil 20°–30° above the normal boiling point

These remarkable observations have attracted much interest and not a little criticism That the behaviour of substances dried by Baker's technique undergoes alteration seems fairly certain, but no quantitative assessment of this change (as distinct, say, from super heating effects in the case of the boiling point) is yet available and no completely satisfactory interpretation of the phenomenon has yet been advanced

Another field of research in which Baker was active was the determination of atomic weights Tellurium, mercury and silver were cases in which collaborators under his direction applied the accurate manipulative methods of which he was a master.

Baker was first and foremost an experimentalist, and his skill in glass-blowing and other practical arts was plain to all who saw him at work. Chemical craftsmanship was his chief joy, and up to within a few weeks of his death, in spite of physical disabilities, he was to be found in his laboratory, devising and constructing apparatus for a fresh attack on old problems. Brereton Baker was a modest man of simple tastes and homely interests whose character and personality secured for him a warm place in the hearts of very many pupils and co-workers

J. C. P.

WE regret to announce the death on May 14, at the age of sixty-eight years, of Prof. Edwin B. Frost, associate of the Royal Astronomical Society, and emeritus director of Yerkes Observatory.

The Slowing Down of Neutrons by Protons

FERMI and his co workers have pointed out that if a neutron source is surrounded by a material rich in hydrogen the neutrons lose energy to the protons on collision, and, after about twenty impacts, their energies are reduced to the order of those due to thermal agitation They tried to discover whether temperature affects the density of such a neutron 'gas' by measuring the activation produced in rhodium by a neutron source surrounded by hydrogenous substances at room temperature and at 200° C No difference in activation was detected[1].

We have performed a somewhat similar experiment by measuring the activity produced in a silver cylinder surrounding a neutron source when both were surrounded (1) by air, (2) by water at room temperature, (3) by liquid hydrogen (– 253° C) The silver was activated to its equilibrium value, and its radioactivity was measured by an ionisation chamber and electrometer The activities in arbitrary units on removal of the silver from the neutron source were found to be —

Arrangement	Maximum activity	Increase in activity divided by the activity produced when in air
In air	29	—
Surrounded by 1500 c c water in a Dewar flask	93	2 2
Surrounded by liquid hydrogen in the same Dewar flask	58	1 1

Because the silver tube separated the neutron source from the liquids, neutrons would pass through it in a manner exactly the same as when the liquids were not present It is therefore reasonable to measure the effect of the liquids by the *increase* in activity which they produced rather than by the total activity.

The hydrogen in water has a density of 0 11 gm /c c while that of liquid hydrogen is 0 07 gm /c c , that is, in a ratio 1·6 1 compared with a ratio of increase of activity of 2 2 · 1 The conditions were not quite so favourable for the production of radioactivity in the case of the liquid hydrogen since it was not possible to make up the loss due to evaporation, so that during the last few minutes—those most important for the activation of the silver—the volume present was less than that of the water It would, therefore, seem probable that the measure in activation of the silver was in proportion to the density of protons which surrounded the silver and the neutron source and that it was not affected by the change in temperature.

Our thanks are due to the Union Minière du Haut Katanga for the loan of the neutron tube and to the staff of the McLennan Laboratory for help with the experiments

Collisions between Neutrons and Diplons

WHEN a stream of neutrons passes through a sheet of matter, neutrons are lost from the beam both by absorption and scattering The latter can be avoided by placing the source of neutrons in the centre of a spherical scatterer, since with this arrangement as many neutrons must be scattered into the beam as are lost from it by scattering In these circumstances any diminution of the number of neutrons in the beam must be attributed to absorption by the material of the sphere The usual method of estimating the intensity of a neutron beam is to measure the induced radioactivity produced in a thin layer of matter such as aluminium or rhodium by means of a tube counter The radioactivity so produced is proportional to the length of the neutron path in the detecting substance and will be given by $k\,n\,d\,\sec\theta_m$ (k, number of radioactive atoms produced per cm path, n, number of neutrons in the beam, d, thickness of the sheet; and θ_m, the mean angle of incidence).

For this reason absorption measurements using a spherical absorber do not necessarily give the true

absorption, since the effect of scattering will be to increase the value of θ_m and thus increase the radioactivity produced. If each neutron is scattered several times, this secondary effect may cause an apparent *increase* in the strength of the beam by a factor as great as 2.

This secondary effect can be eliminated by using a sphere of detecting material instead of a sheet, and we have used this method to investigate the passage of fast neutrons through heavy water.

The beryllium radon source was placed at the centre of a spherical flask containing the heavy water* (98·4 per cent), the whole was surrounded by a nickel cylinder which had the small spherical detectors stuck on its inner surface. After activation, the cylinder was slipped over a cylindrical aluminium counter for measurement. The following results were obtained.

Absorber	Detector	Absorption (per cent)	Effective cross-section
D_2O	Al (${}_{12}Mg^{27}$)	11	7·0 × 10[illegible]
D_2O	Si (${}_{13}Al^{28}$)	15	9·7 × 10[illegible]
D_2O	P (${}_{14}Si^{31}$)	12	7·7 × 10[illegible]
H_2O	Al (${}_{12}Mg^{27}$)	13	8·4 × 10[illegible]
H_2O	Si (${}_{13}Al^{28}$)	13	8·4 × 10[illegible]
H_2O	P (${}_{14}Si^{31}$)	11	7·0 × 10[illegible]

The reduction in the activity of the detectors excited by the neutron beam can be accounted for in two ways: either neutrons are removed by true absorption or, after being slowed up by a collision, the neutrons are less effective in exciting artificial radioactivity.

If true absorption were a significant factor in our experiments, one would expect a marked difference between the absorption in heavy and light water; since this is not found it seems probable that the observed reduction is due to the differential slowing up of the neutrons.

Owing to the smaller mass, the velocity of neutrons is reduced by a greater amount on collision with a proton than on collision with a diplon. The simplest interpretation of our results is that the velocity excitation curve for silicon, aluminium and phosphorus rises steeply as the velocity is increased and then remains fairly independent of velocity within the range of velocities used.

That the neutrons actually do suffer a greater decrease in velocity on colliding with protons is confirmed by independent experiments on the excitation of silver (Fermi effect). As Fermi showed, silver is much more strongly excited by neutrons which have been slowed up by collision with protons than by the same neutrons before they have been scattered. We found in agreement with the experiments of Herszfinkiel, Rotblat and Zyw[1] that, although the activity induced in silver is increased by passing the neutrons through heavy water, the increase is only about one third of that produced by the same amount of ordinary water.

Thus the results of our experiments can be accounted for in an elementary way as being due to the large difference in mass between the diplon and the proton.

Evidence on the Velocities of 'Slow' Neutrons

WE have searched in a number of ways for experimental evidence of the existence of neutrons of thermal energies, using a radon-beryllium source of fast neutrons and allowing them to diffuse through materials rich in hydrogen[1]. Until very recently we could find no such evidence, but repetition of one of our early trials, under much improved conditions, has strongly suggested the presence of such very slow neutrons.

Specimens of silver, rhodium and iodine (the last in an envelope of thin glass) were placed in turn within a long hollow paraffin wax cylinder the inner and outer radii of which were respectively 2·1 cm. and 3·7 cm. The cylinder fitted closely into a Dewar vessel which itself was surrounded by wax to a thickness of about 7 cm. The source was placed in a cavity in the outer wax. We observed the β-ray activity induced in each specimen with the whole apparatus at room temperature; the inner wax cylinder and the specimen were then cooled to the temperature of liquid oxygen (90° K.) and the observations repeated. The thermal capacity of the wax sufficed to prevent serious rise of temperature during irradiation. The specimens were allowed to regain room temperature before being presented to the counter.

The ratios of the activity induced with the wax cold to that with the wax at room temperature were found to be as follows: 1·26 ± 0·04 for silver (25 sec. period); 1·29 ± 0·04 for silver (150 sec.); 1·23 ± 0·07 for rhodium (44 sec.); but 0·84 ± 0·06 for iodine (25 min.). The change in the linear dimensions of the cylinder did not exceed 1 per cent. We conclude that an appreciable proportion of the neutrons concerned had energies comparable with those of thermal agitation, and were able to attain some measure of thermal equilibrium with the medium through which they were passing.

Fermi and his collaborators[2], using a rhodium detector in a medium of liquid hydrocarbons, have found no variation of the activity induced at 200° C. from that at room temperature. We tried with a silver detector in an oil bath up to 250° C., and found a decrease of about 20 per cent. The increase of volume of the oil due to the rise of temperature was, however, of similar order of magnitude; our result was thus inconclusive.

The difference between the behaviour of iodine and that of silver and rhodium would seem to indicate that iodine absorbs preferentially neutrons of velocities different from, and probably higher than, those which are most effective in the other cases. In this connexion we may mention that we find the absorption of 'slow' neutrons by a block of iodine to be greater for an iodine detector than for detectors either of silver or of rhodium.

The radon was generously given to us by the Radium Committee of the Medical Research Council, through Prof. S. Russ.

The Fermi Proton Effect in Silver

In the course of investigating the radioactivity induced by the neutron produced by the bombardment of diplogen with diplons, we observed that the yield of radio element produced in silver increases by a factor of about ten when the sample of silver was surrounded by a layer of paraffin 3·5 cm in thickness during the exposure, showing the Fermi proton effect. The decay curve obtained with the Geiger counter is shown in Fig 1, which suggests the fact that it cannot be expressed by a single exponential curve The apparent value of half-period is about 30 sec at the beginning, becoming approximately 2 minutes at 4 minutes after the bombardment ceased

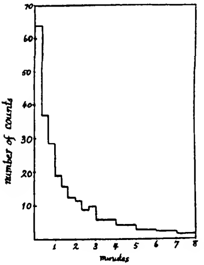

FIG 1

J Bjerge and C H Westcott have reported that the ratio of the yield of radio-element produced in silver by beryllium-radon neutrons to that by the diplogen-diplon neutron is about 100 to 15 It is generally accepted that the mean energy of the neutron is greater in the former case We have therefore two alternatives In the first case we consider the beryllium-radon neutron to contain an appreciable amount of components softer than that of the diplogen diplon neutron and these softer components were effective in the experiment of Bjerge and Westcott In the second case, the yield of radio-element produced in silver is not a monotonic function of the energy of the neutron, decreasing with decreasing energy from the region of energy of the beryllium-radon neutron to that of the diplogen diplon neutron, but below this value of energy it increases with decreasing energy In this argument it is assumed that the Fermi proton effect is due to the decrease of energy of the neutron by its collision with protons

Radioactivity of Potassium

KLEMPERER[1] has recently shown that postulation of the existence of a radioactive isotope, $_{19}K^{40}$, with a large nuclear spin, affords the most likely explanation of the radioactivity of potassium He appears, however, to have over-estimated the value of the nuclear spin (i — 4 or 5 units) necessary to obtain a sufficiently high half value period for the isotope Klemperer made use of a statement due to Gamow[2], which was based on theoretical reasoning The latter author reached the conclusion that, if two radioactive elements possess the same upper velocity limit in their β ray spectra, and if one of them suffers unit change in nuclear spin during decay while the other preserves its spin unchanged, then the ratio of their half value periods is about 100

However, if the value of 700 electron-kilovolts for the upper velocity limit of the β particles emitted by potassium is inserted in the Sargent equations between decay-constant and energy (as given by Klemperer), 250 days is obtained for the half value period on the assumption that $\Delta i = 1$, and 36 minutes on the assumption that $\Delta i = 0$ in the decay These periods stand in the ratio of 10^4, and not 10^2 From the actual curves of Sargent[3], a value of about $10^{3 \cdot 2}$ is derived for the same ratio These figures are considerably higher than that quoted by Gamow, and are probably more acceptable in view of the facts that the theory is only an approximate one and that Gamow states that the ratio may be considerably in excess of 100

On the supposition that the half value period is increased by a factor lying between $(2{,}000)^{\Delta i}$ and $(10{,}000)^{\Delta i}$ when the spin changes by Δi during the radioactive transformation, it is necessary to assign a spin of only 2 to 3 units to the nucleus of the hypothetical isotope in order to increase its half-value period to a reasonable figure

In conclusion, it may be pointed out that Klemperer's views are supported by the fact that the isotope, $_{19}K^{40}$, the existence of which has been definitely established by Hevesy and Høffer Jensen[4], is also a misfit as regards the Sargent relations Here again, the existence of quite a small nuclear spin of this isotope would clear up the contradiction between β velocity and life-time

Induced β-Radioactivity by α-Particle Bombardment

LORD RUTHERFORD'S classical experiments showed that the emission of protons from the nuclei of the light elements, when these were bombarded with α-particles, was a fairly general phenomenon No protons, however, were observed from helium, lithium, beryllium, carbon or oxygen These results are significant, and suggest that $_2He^4$, $_6C^{12}$ and $_8O^{16}$ are very stable structures, probably consisting of close combinations of α particles The great stability of these isotopes is confirmed by Aston's work and by their behaviour under bombardment by high-speed ions. But both lithium and beryllium are

disruptible by α-particles with the emission of neutrons, and while the structure $2\alpha+n$ for ${}_4Be^9$ will explain why no protons are emitted from this isotope under α-particle bombardment, it is difficult to see why no proton emission has been observed from lithium when bombarded with α-particles

In addition, it has been found that all elements which emit protons under α particle bombardment also emit neutrons, and, moreover, that many nuclei emit both protons and neutrons It is significant that neutron emission followed by positron radioactivity has been observed by Miss Meitner[1] when lithium is bombarded by α-particles, and this suggests that proton emission from this element should also be observed The reaction detected by Miss Meitner is :-

$$ {}_3Li^6 + \alpha \rightarrow {}_5B^9 + n\uparrow, \quad {}_5B^9 \rightarrow {}_4Be^9 + \overset{+}{e}\uparrow, $$

and we should therefore expect to observe

$$ {}_3Li^6 + \alpha \rightarrow {}_4Be^9 + p\uparrow $$

In addition, the neutron and proton emission from boron, namely,

$$ {}_5B^{10} + \alpha \rightarrow {}_7N^{13} + n\uparrow, \quad {}_7N^{13} \rightarrow {}_6C^{13} + \overset{+}{e}\uparrow, $$

$$ {}_5B^{10} + \alpha \rightarrow {}_6C^{13} + p\uparrow \text{ and } {}_5B^{11} + \alpha \rightarrow {}_7N^{14} + n\uparrow, $$

as well as the emission of both protons and neutrons from ${}_7N^{14}$ and ${}_9F^{19}$, ${}_{11}Na^{23}$, ${}_{13}Al^{27}$ and ${}_{15}P^{31}$ suggest, therefore, that the following reactions from the structurally similar nuclei ${}_3Li^7$ and ${}_5B^{11}$ should be possible.

$$ {}_3Li^7 + \alpha \rightarrow {}_4Be^{10} + p\uparrow $$
$$ {}_3Li^7 + \alpha \rightarrow {}_5B^{10} + n\uparrow $$
$$ {}_5B^{11} + \alpha \rightarrow {}_6C^{14} + p\uparrow $$

It is significant that ${}_4Be^{10}$ and ${}_6C^{14}$ are β radioactive, so that these actions indicate that the delayed emission of 'negative' electrons should be observed from lithium and boron when these elements are bombarded by α particles of suitable energy The detection of such β radioactivity with lithium would be evidence in favour of proton emission from this element

In a similar way, the production of β radioactive isotopes by proton emission from isotopes such as ${}_8O^{17}$, ${}_{10}Ne^{21}$, etc , for example,

$$ {}_8O^{17} + \alpha \rightarrow {}_9F^{20} + p\uparrow, \quad {}_{10}Ne^{21} + \alpha \rightarrow {}_{11}Na^{24} + p\uparrow, $$

is possible The abundance of these isotopes is, however, too small for such reactions to be detected experimentally As, however, ${}_3Li^7$ and ${}_5B^{11}$ are the more abundant isotopes of lithium and boron, we anticipate that the induced β-radioactivity due to ${}_4Be^{10}$ and ${}_6C^{14}$ should be experimentally detectable

A Completely Supraconducting Galvanometer

SINCE it was thought that interesting experiments might be performed if it were possible to measure quantitatively persistent currents in a supraconducting circuit much smaller than have so far been detected with a magnetometer, there has been constructed in this laboratory a completely supraconducting moving-coil galvanometer. The coil consists of 100 turns of fine lead wire, connected by leads of lead to the experimental circuit The coil is suspended in the liquid helium by a rigid wire connected above the cryostat to an ordinary galvanometer suspension and mirror. With this arrangement the suspension remains nearly at room temperature The coil is completely shielded from moderate external magnetic fields by placing it inside a supraconducting cylinder of sheet lead, and thus is subjected only to the controlling magnetic field from a pair of copper coils within the cylinder

Mathematical investigation of the characteristics of a resistanceless galvanometer showed that its behaviour would be interesting, apart from its possible applications Assuming that, when the external circuit is also supraconducting, the whole can be treated as a circuit having zero resistance and self-inductance L, it was found

(1) With a persistent current i_0, such that the deflection when there is resistance in the circuit would be $d_0 = Ki_0$, the coil should oscillate, undamped except mechanically, about a point

$$ d' = d_0\left(1 + \frac{n^2A^2H^2}{kL}\right)^{-1} $$

where nAH is the flux linked with the moving coil in its control field, and k is the torsion constant of the suspension

(2) For a given current i_0 the deflection should be a maximum, $d' = \frac{1}{2}d_0$, when $H = \sqrt{kL}/nA$.

The galvanometer has been tested by connecting it to a supraconducting tin coil in which a persistent current could be induced by means of an external magnetic field As first constructed, the coil oscillated as expected, damped only by the small viscosity of the liquid helium, but proved to be unsteady When artificial oil damping was introduced, the practical behaviour of the instrument was entirely satisfactory The deflections were found to depend in the manner expected upon the control field H, and can be used to give quantitative measurements of the current The sensitivity of the present instrument at the optimum field is about 5×10^{-5} ampere per mm

This confirmation of the predicted behaviour shows definitely that true persistent currents throughout the circuit were induced, agreeing quantitatively with the law of induction, when the field was applied to the tin coil In view of recent experiments upon the effects of magnetic fields upon supraconductors, it is interesting to note that the same deflection is obtained whether the control field is altered before or after the tin portion of the circuit becomes supraconducting, or before or after the persistent current is induced

Some of the experiments in which an instrument of this kind may be of use are

(1) Further investigations of the thermoelectric effect between two supraconductors around their transition points

(2) An attempt to settle the still doubtful question of the Hall effect in a supraconductor.

(3) Experiments on the distribution of persistent currents

(4) Studies of persistent currents which may throw some light on the recently discovered anomalous magnetic behaviour of certain supraconducting alloys

The Dyestuff Industry

WHILST in general agreement with the admirable article on "The Dyestuffs Industry and its Lessons", in NATURE of April 27, I cannot endorse your acceptance of Mr. C J T Cronshaw's argument that "the industry languished because the pioneer spirit and the creative instinct which brought it into being abandoned it too early" I hold that the breakdown was entirely on the side represented by Mr Cronshaw—the managerial and commercial side Often in the distant past have I discussed the problem from this point of view with Griess, Caro, Dewar, Witt, Meldola, Martius and others The commercial community is not likely to recognise this, simply because the scientific spirit is foreign to its nature

Mr Cronshaw attributes our downfall to the too early retirement of Perkin and others I fear he has not the necessary feeling for the conditions prevailing in Perkin's time History cannot be written at a distance from the events by those who have had no direct knowledge of the period considered and of the men concerned I have more than once discussed the situation, most recently in an article in the *Pharmaceutical Journal* (April 29, 1931)

Perkin's retirement meant nothing, except that he was beaten in the race His original discovery of the dyestuff Mauve was a pure fluke His great and real discovery was of himself- of his inborn, outstanding ability as a chemical engineer, to use the now fashionable term He built up the industry from nothing—in particular, he transferred chemistry from glass to iron On the other hand, he proved himself to be without imaginative power—the additions he made to the colour palette were negligible. His second advance with alizarin was inspired from Germany and was again due to his constructive ability He worked too much in secret and failed until too late to foresee the need of a fully organised system of prospecting the field In fact, he was himself too narrowly trained He worked all but alone The real advance in the industry came through E. C. Nicholson and Hofmann through their expansion of the Rosaniline industry In fact, the initial establishment of the dyestuff industry in England was the work of the triumvirate, Perkin, Nicholson and Hofmann Perkin only led off Long before Perkin retired, the fate of the industry was sealed, already in 1865, when Hofmann returned to Germany, outwearied by his attempts to create a school here I began to study chemistry under him just before he left. Great as was the work he did, sound and broad as were the foundations he laid in aniline, our commercial outlook was too narrow and unintelligent for us to utilise his services Our men of means and our manufacturers did not send their sons to him His work was largely done with German assistants.

When Hofmann left the country and Nicholson retired, Perkin was left pivotless; the example they had set him was withdrawn. He made his wonderful spurt, on his second horse Alizarin, without any support from a field; soon he was left scurrying alone across the course. Nicholson had retired because his partners would not move with the times When the firm acquired Perkin's business, it was only to prove itself unable to carry the burden On Playfair's advice, both Griess and Dewar were approached but offered pettifogging terms The firm took Meldola and later on Green but did not know how to use either with effect

Our downfall was just lack of business wit it was due to our complete failure to place ourselves upon a scientific footing Williams, Thomas and Dower missed our third opportunity—that which Otto N Witt gave them, of leading in the azo-dyestuff industry- long before Duisberg's advent Griess and Witt, properly used together, could have established the industry here well in advance of the Germans

We are not out of the wood to day Our industry is insufficiently organised on the technical side far too narrowly commercial in its outlook The Germans have succeeded, not through one man management but through the close association of technical and commercial interests The main result of our so-called rationalisation has been to eliminate technical ability and understanding to a more than dangerous extent We are to day, I believe, in most serious danger of again being beaten by German scientific organisation. We cannot think in high places the commercial mind still prevails and will not brook true technical leadership Something more than the mere association of a few academic professors with the industry is needed In fact, the signs are only too clear that we are no longer making the progress we should if indeed we are 'holding water'

Mutation Rates in Man

THERE is at present no information concerning mutation rates in vertebrates But where a gene produces a very great unfitness from the Darwinian point of view, that is to say, greatly diminishes the mean number of offspring produced by its bearers, then it will tend to disappear if its numbers are not kept up by mutation The rate of disappearance is extremely slow for an autosomal recessive, very rapid for a dominant or a sex linked recessive

Epiloia, or tuberose sclerosis, is a condition in which tumours of the skin, brain and sometimes of the heart and kidney, are liable to be associated with epilepsy and mental deficiency The mortality rate is high in severe cases, and probably most affected individuals have no children Pedigrees of the condition show that it is an autosomal dominant In each generation, however, a proportion of cases, which we estimate at about 25 per cent, are sporadic and are presumably due to mutation The frequency of epiloia in south-eastern England appears to be of the order of 1 in 30,000 This implies a mutation rate of about 1 in 120,000 per generation

Hæmophilia is a sex-linked recessive condition It is so fatal that the marriage rate of hæmophilics is about a quarter of the normal, and their actual fertility doubtless still lower In other words, three quarters or more of the hæmophilic genes in males are wiped out in each generation, and must be replaced by mutation if the population is in equilibrium. A simple calculation shows that, if there were no mutation, the incidence of the disease would be decreasing at such a rate that 1,000 years ago the whole population of England would have been

hæmophilic Several human pedigrees show that hæmophilia may arise by mutation The frequency of hæmophilia in London males certainly exceeds 1 in 100,000 at birth and may well exceed 1 in 30,000 A rough estimate of the mutation rate is 1 in 50,000 to 100,000 per X chromosome per generation

Several other sub lethal dominant conditions, such as neurofibromatosis, seem to have frequencies, and therefore mutation rates, of the same order The highest mutation rate known for any locus in *Drosophila* is about 1 in 300,000 for the white locus Thus if we take the generation, and not, of course, the year, as unit, man seems to be somewhat more mutable than *Drosophila* A full account of our investigations will be published elsewhere

A New Virus Disease of Tomatoes

IN 1931 the first appearance in Europe of the tomato virus disease known as 'spotted wilt' was recorded by this virus station[1] Since that date, the disease has spread through the length and breadth of *Great Britain*, and its ability to attack ornamental plants of all kinds has made the virus one of the major problems of the horticulturist

In view of these facts, it may be worth while recording the recent appearance of an apparently new and equally serious virus disease of tomatoes The virus in question was isolated from some diseased tomato plants sent in for examination, and the symptoms it produced on the various experimental plants differed from any with which I am familiar On tomato the symptoms are briefly as follows The first signs of infection, developed on the fifth day following inoculation, were pronounced yellowing of

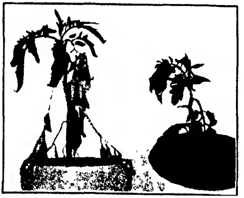

FIG 1 A new virus disease of tomatoes, the lesion in the stem at soil level (right hand plant) is characteristic

the inoculated leaves together with the appearance of yellow or purple rings or circular necrotic spots Later, the youngest leaves showed a tendency to twist round and become pale yellow in colour The next development was the appearance of a gross lesion on the stem, at and just below soil level, this was followed by a general wilting and collapse of the plant (Fig 1). The stem lesion appeared to be more characteristic of infection of younger plants

The virus causing this disease has been differentiated from all the known viruses affecting tomatoes in the British Isles by ultra-filtration and immunity studies, by its physical properties and particularly by its symptom expressions on differential hosts The unusual reaction of the virus upon cowpea, *Vigna sinensis* (Fig 2), is alone sufficient to differentiate it from the viruses of the tomato streak group

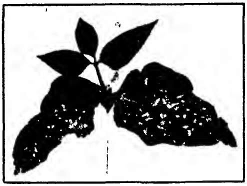

FIG 2 The tomato virus upon cowpea the virus is usually confined to the inoculated leaves

I wish to express my indebtedness to Mr Lawrence Ogilvie, of the Long Ashton Research Station, Bristol, who sent me the affected plants

Pleistocene Coastal Deposits in Palestine

ANYONE who has travelled by train along the coast of Palestine from Haifa to Ludd cannot have failed to notice, soon after rounding the northern point of Carmel, a low ridge of sandstone running roughly parallel with the railway line and the sea It begins 5 km to the south of Cape Carmel, and continues for approximately 32 km

The Crusader's Castle at Athlit was built with stone taken from this ridge, and more recently, in 1930, two big quarries were opened in it to the north of Athlit Station to supply the stone for the great breakwater of Haifa harbour

The rock of which the coastal ridge is formed has generally been regarded by geologists as a marine formation of Pliocene age, and had not attracted the attention of prehistorians In the course of a short visit to Athlit in April of this year we decided to devote some time to this problem, and two days were spent in a close examination of the area In the quarry sections, which have an average height of about 13 m and are more than half a kilometre in length, the following observations were made.

(1) The ridge is mainly composed of wind-blown sand showing typical æolian current bedding, and containing comminuted shells.

(2) A conspicuous layer of red earth varying in thickness from a few centimetres to 1 m divides the sandstone into two approximately equal series.

(3) In this layer a considerable number of flint implements were found at various points.

(4) Land shells occur in both the upper and lower sandstones and in the red earth

It was at once evident that the flints were not of any considerable age—certainly not Pliocene The most interesting specimens found *in situ* were a side-scraper of Mousterian type and two small Levallois cores The remainder were mere chips and small flakes Among those found adhering to fallen blocks, or on the quarry floor, were three good Levallois flakes, a rough circular scraper, and a Levallois core, the remainder were small flakes and chips So far as can be judged from the material at our disposal, the industry closely resembles the Upper Mousterian found in the caves of the Wady Mughara (Mugharet-El-Wad, Layer G, Et Tabūn, Layer B)

It seems safe to conclude that the bulk of the ridge is relatively late Pleistocene in age, and that it is essentially æolian in origin

These discoveries raise more than local problems in Palestinian geology and prehistory, and we propose early next year to make a detailed investigation, not only of this ridge, but also of the coastal deposits southwards

Cambridge E. W. GARDNER

Dielectric Polarisation of Phenol

IT is well known that the molecular polarisation of alcohols in a non polar medium is exceptional in that it at first increases with concentration and then falls finally to a lower value than that at which it started The data of Williams and Allgeier[1] show that at 25° up to a molar fraction of 0·345 the polarisation of phenol in benzene is constant, whilst those of Donle and Gehrckens[2] show a decrease in polarisation at 22° up to a concentration of 0·05 molar fraction phenol and those of Philip and Haynes[3] an increase at 20° in dilute solutions I have measured the polarisation of phenol in benzene at 70° with the following results:

c_2	ε	d	P_2
0·10737	2·540	0·84750	73·43
0·13464	2·639	0·85340	73·56
0·20170	2·934	0·86808	75·35
0·20330	2·943	0·86804	75·55
0·32460	3·567	0·89425	76·20
0·40717	4·063	0·91188	75·85
0·45454	4·375	0·92147	75·52
0·59956	5·458	0·95200	73·79
0·72570	6·517	0·97812	69·78
1·00000	9·161	1·0307	66·72

c_2 is the molar fraction of phenol, ε is the dielectric constant, d is the density, and P_2 is molecular polarisation of phenol The molecular polarisation of benzene at this temperature is 26·928

The behaviour of phenol at this temperature appears to be similar to that of the lower alcohols, which would be expected from its hydroxylic nature

These results give a value of ∞P_2 of 71·0, which, if we take $P_E + P_A$ to be 31·0[4], gives 1·5 debyes for the dipole moment, compared with the values 1·55 of Donle and Gehrckens and 1·70 of Williams

Catalysis of Ester Hydrolysis by D_3O^+ Ions

IT has been observed by Moelwyn-Hughes[1] that the catalytic influence of D_3O^+ ions on the inversion of cane sugar in heavy water is greater than that produced by H_3O^+ ions in ordinary water, and Schwarz[2] observed that the acid hydrolysis of methyl and ethyl acetates takes place about 50 per cent more quickly in heavy than in light water under similar conditions

The rate of hydrolysis of methyl acetate in sulphuric acid solutions has been determined by means of a viscosity method by which the whole reaction can be followed with less than 1 c c of solution, and it is found that the ratios of the catalytic coefficients in heavy and light water (taking the sulphuric acid as completely dissociated in both cases) are $k_{D_3O^+}/k_{H_3O^+}$ = 1·86 at 15° and 1·68 at 25° These ratios are nearly the same as those found by Moelwyn-Hughes for the inversion of cane sugar

Esterification of Phosphate in the Respiratory Breakdown of Sugar in Higher Plants

HARDEN and Young[1] showed that phosphate undergoes an important cycle of changes in the fermentation of sugar by yeast juice, being first converted into a hexosephosphoric ester and finally liberated as inorganic phosphate when all the sugar was fermented Recently, Meyerhof[2] showed an identical condition in the production of lactic acid from hexose in muscle extracts The view has therefore been expressed that esterification with phosphoric acid may be a necessary step in the biological degradation of sugar In the higher plants, however, there has been no direct proof of esterification in respiratory sugar metabolism, though a close parallel between alcoholic fermentation and anærobic respiration has been assumed from the first and has been confirmed not only by the discovery of identical enzymes in both, but also by the fact that phosphate stimulates plant respiration Phosphate has also been shown to disappear when added to ground peas[3], and phosphoric esters have even been isolated from plants[4]

I have obtained definite results on this phase of sugar breakdown in higher plants by devising a method of preparing cell free glycolytic aqueous extracts (stable for a few hours) by plasmolysing fermenting peas (*Pisum sativum*) The fresh extract, presumably containing the full zymase-complex in solution, actively ferments glucose, fructose or sucrose with evolution of carbon dioxide, under strictly aseptic conditions In order to follow esterification and sugar breakdown, 40 c.c of the fresh extract at pH 6·2, after nitrogen had been bubbled through, was incubated with glucose, in presence of toluene, at 30° C A suitable quantity of a phosphate buffer was added and samples withdrawn after every 5–15 minutes of mechanical shaking The value of inorganic phosphate in the trichloracetic acid filtrate

of the samples, as determined by the Fiske and Subbarow method, was found to fall rapidly and steadily and rise again in 30–60 minutes nearly to, but sometimes above, the original level, while glucose (Folin's blood sugar method) showed a fall at the beginning, then a rise and next a rapid and steady fall from a point where all the esterified phosphate was beginning to be liberated This result has been repeatedly and consistently obtained with extracts from several varieties of peas, not from ground peas alone When efforts were made to measure the carbon dioxide output in response to phosphate in a differential manometer, the large amount of colloidal protein present as impurity in the extract interfered by holding large quantities of the gas

This demonstration of phosphate esterification brings the higher plant (pea) fully in line with yeast and animal muscle in this respect But it is to be expected that when the new problems confronted in these cell free extracts are fully investigated, the course of respiratory sugar breakdown in higher plants may have its own individual peculiarities, as in fact further new results I have obtained seem to hint Detailed results, and the method of preparing the extracts, are to be published shortly elsewhere

Application of Microchemical Tests in Assessing the Quality of Ash Timber

DURING the last few years, attention has been given in this laboratory to the study of the anatomical structure of ash timber in relation to the maximum crushing strength in compression parallel to grain Consignments of trees from seven localities have been studied, and each site had a distinctive strength specific gravity regression Variations in the amount of wood substance per unit volume, therefore, do not account completely for variations in strength, and it has been shown that the arrangement of the wood substance in the annual ring also influences the mechanical properties[1] The fact, however, that specimens of equal specific gravity and closely similar anatomical structure sometimes differ by more than 30 per cent in maximum crushing strength suggests that still other factors are involved and that probably the physical and/or chemical nature of the wood substance is of great importance in determining strength

Several methods of examination were tried in comparing pairs of specimens of strong and weak types of timber, the individuals of each pair being matched in respect of specific gravity and gross anatomical features, but differing considerably in strength It was discovered that a phloroglucin-hydrochloric acid solution could be used to distinguish between the members of each pair In strong specimens, the whole of the fibre-walls stained red, and in the weakest type the middle lamella region stained a faint pink, the secondary walls remaining unstained All intermediate types of staining were observed

So far, the method has been applied with success to timber tested in compression parallel to the grain It has also indicated excessive weakness in a number of defective hockey sticks, and it is intended in the immediate future to investigate the toughness of ash by the same method

With regard to the nature of the chemical reactions involved, it is not at present possible to do more than direct attention to the fact that of the so-called standard lignin reagents, phloroglucin-hydrochloric acid is apparently the only one capable of differentiating between strong and abnormally weak types of timber

The Classification of Coals

FROM a chemical point of view may I dissent from much that is said about the Stopes nomenclature for the visible ingredients of bituminous coals in Dr Lessing's article in NATURE of April 27

In the first place, there seems to me to be nothing particularly new or advantageous in it Every observant person knows that bituminous coal is usually composed of bright and dull layers, and for a century or more those have been distinguished as the 'bright coal' ('Glanzkohle') and 'dull coal' ('Mattkohle') respectively It has also been long known that between such layers there is an amorphous powdery substance that blackens the hands, and commonly called 'mineral charcoal', or by miners the 'dant' I have never been able to see any sufficient reason for substituting such terms (imported from France) as 'vitrain' and 'clarain' for the 'bright coal', 'durain' for the 'dull coal' and 'fusain' for the 'mineral charcoal' or 'dant', unless indeed for consistency 'charbon' be also substituted for 'coal' in naming the main substance Inasmuch as such substitutions have tended to mystify people, and to make believe that somehow or other coal is better explained thereby, I deprecate the further elaboration of them referred to in Dr. Lessing's article

Secondly, I think the article misleading in saying that "the subdivision of coal into the four visible Stopes ingredients has been widely accepted in Great Britain and in most European countries" without indicating that, outside the exclusive circle of the 'Coal Research Club', it has been much criticised and by no means generally adopted

Throughout the systematic researches into the chemical constitution of coals and their maturing which for years past have been carried out in my laboratories here, and which have comprised coals from all parts of the world and representative of all stages in the peat → brown coal → lignite → bituminous coal → anthracite series, the Stopes nomenclature has been of little assistance, and I venture to think it has no chemical significance. Our experience does not support Dr Lessing's statement that its four isolated components are "different and typical in their chemical composition . . . associated with mineral matter in characteristic amount and composition . . [and] contain groups of organic

compounds and plant residues in defined ratios". Moreover, although it has been repeatedly suggested that the coking propensities of bituminous coal reside in the 'vitrain', we here disbelieve it.

It seems to me that a scientific classification should not only be applicable to all types of coals but also have a more fundamental basis than any yet proposed.

WILLIAM A. BONE.

Imperial College of Science
and Technology,
London, S.W.7.
April 29.

AN adequate and reasoned reply to Prof. Bone's letter would require more space than, as I am given to understand, NATURE can afford; I must, therefore, let the statements in my article, which I endeavoured to make in a critical and impartial spirit, speak for themselves.

I may, however, be permitted to refer to two points raised in Prof. Bone's letter. A perusal of the literature on the formation and the chemical and petrographic constitution of coal and its commercial preparation and utilisation during the last ten years provides evidence of the wide use of the terms proposed by Stopes and of the acceptance of what they are intended to signify. I tried to make it clear in my article that only qualified acceptance has been accorded to them in some quarters.

Prof. Bone's experience that the isolated coal components are not different and typical in their chemical composition is contrary to the results of hundreds of analyses and carbonising tests published by workers in Great Britain and many other countries. My own work on the behaviour of the coal components during carbonisation, and on the composition and distribution of the mineral matter in coal, furnishes ample proof for the statement made in my article. However, by its very nature the composite character of coal does not permit of ready generalisation, and if Prof. Bone is aware of cases in which typical differences in composition between coal components or their ashes cannot be recognised, he would earn the thanks of other workers interested in the subject for bringing these exceptions to their notice.

Philosophy and Modern Science

WHEN I read Dr. H. Dingle's book "Science and Human Experience" I found that I agreed with nearly all of it; now I find myself in disagreement with most of his article in the Jubilee issue of NATURE. I realise that he may not be expressing his own views, but be trying to summarise those of others, and that most of those he expresses are prevalent; but I cannot convince myself that they are right. The differences begin with what he calls the fundamental principle of the rejection of unobservables. No distinction is made between sensations and concepts. Dr. Dingle makes general observability part of his criterion; since each sensation is private to one individual, he thereby leaves the whole basis of our experience out of science. The principle cannot be applied to concepts, because in fact they are not observed by anybody. If we are realists we may say that they are inferred; if we are phenomenalists we may say that they are constructed. If there is any change in scientific thought in this respect, it is that our realists have now a greater disposition to modify their ideas of *what* is real when new data derived from sensation become available.

The scientific validity of a concept in fact depends on quite different criteria; it depends on whether the concept and the postulated laws that it satisfies help to co-ordinate our sensations. If different people find the same concepts useful, that is because to a considerable extent they have similar sensations and similar processes of thought; but what are sensations to one are concepts to another. The rejection of unnecessary concepts is not a fundamental principle at all; it is a practical rule of method, like not putting six pairs of knives and forks on the table for a two course dinner. Thus I cannot agree that the rejection of absolute position was the great feature of the principle of relativity; the important thing was the statement of the laws satisfied by relative position. Admittedly the method made the detection of the law easier; that is why it was a good method. But the important thing was the application of the principle that a formally simple law has an appreciable *a priori* probability. I have shown in my "Scientific Inference" that this principle is fundamental, and that without it we could never attach a high probability to any quantitative law however often it is verified; but though it is universally used, people seem to have a curious reluctance to admit that they are using it. Let us respect the broom; but there is no need to be ashamed of the electric light.

The confusion between sensations and concepts again vitiates Dr. Dingle's answer to the question 'Do things exist when they are not observed?' Sensations obviously do not; but would Dr. Dingle return the answer 'No' to the question, 'Did Neptune exist before it was observed?' The fact is that when we say we observe a thing we do nothing of the sort; we have certain sensations and we assert the result of a long chain of inference from them, which is not the shorter because we have made inferences of the same type so often that we carry them out rapidly and often forget that they are there. The perturbations of Uranus afforded just the same kind of ground epistemologically for inferring the existence of Neptune that a telescopic observation does.

The 'principle of causality', again, has no scientific status. As has been repeatedly pointed out, nobody has ever succeeded in stating it in such a way that it will help us to say *what* laws are causal. We know of many actual causal laws, and there is reason to believe that many others remain to be discovered; but the notion of a universal principle of causality is by nature incapable of verification and in practice useless. What is used in practice, consciously or not, is the simplicity postulate.

I am mystified by Dr. Dingle's statement that a probability is the ratio of two integers. Given that a point is equally likely to be anywhere within a length a, what is the probability that it lies within distance $a/\sqrt{2}$ of one end? Or does he contemplate a field such that all distances between possible positions are integral multiples of some universal length, so that continuous variation is excluded?

HAROLD JEFFREYS.

St. John's College,
Cambridge.

THE necessity for condensed expression is, I think, responsible for the questions raised by Dr Jeffreys I admit (indeed, insist on) the distinction between sensations and concepts, but left it unstated because I thought it was implied in the language used The principle of rejection of unobservables must refer only to concepts, we cannot speak of observing sensations because a sensation is an observation, not a thing to be observed I cannot reject a sensation of whiteness which may come to me, but I can reject the concept, ghost I do not share Dr Jeffreys's objection to the phrase, "observing a concept" (for example, observing Neptune) It is unambiguous and far more concise than any alternative which his letter suggests

I agree completely (though I should express it differently) with Dr Jeffreys's paragraph containing the question, "Did Neptune exist before it was observed?" If that question has a meaning, the answer is the ordinary commonsense one—yes, for Neptune is conceived as an object existing in space and time This answer, however, contradicts the principle of rejection of unobservables, so we must ultimately (for scientific purposes of course, not for practical life) give up the concept, and then the question becomes meaningless It is the task of science to discover the significant substitutes Twenty years ago the question was asked Does an electron exist during a transition between two Bohr orbits? We do not now answer yes or no, but abandon the concept of a spatio temporal electron moving from orbit to orbit

Dr Jeffreys's probability problem, as he says, involves continuous variation and therefore is irrelevant Science aims at the correlation of observations which are discrete Hence, unless we wish to correlate unobservables at the same time, the only kind of probability which is applicable is that involving integers, for example, statistical probabilities such as the familiar ones deduced from experiments on throwing dice

The difficulties of mutual understanding in these matters are illustrated in an amusing way by the letters of Dr Jeffreys and Prof Levy The former admits that the views I expressed are prevalent but thinks they may not be mine The latter regards them as not only not prevalent, but also essentially my own private analysis!

Existence of Three Alum Structures

THE crystals which comprise the alum series have generally been considered to be isomorphous on account of the similarity of their chemical formulæ and of their crystal classes The more direct evidence of X-ray diffraction shows, however, that there are at least three different structures involved It is proposed to call these the α, β and γ structures, in order of their discovery

The α structure is that of potassium alum[1], and of the other common alums which have been examined The β-structure is that of methyl-ammonium alum[2] and of cæsium alum, though the α structure can be induced in the former by deposition on rubidium alum Sodium alum is the sole example so far found of the γ-structure

The presence of the form {210} on crystals grown from neutral aqueous solution seems to be characteristic of the β-structure This property provides an easy way of separating cæsium and rubidium alums, for crystals grown from a solution of the two can be distinguished by eye

The non isomorphism of the alums raises doubts concerning other series of salts Nevertheless, it is probable that only in the cubic system can such pseudo-isomorphism exist, for the high symmetry is due to that of the component groups, and may be maintained with different arrangement of these groups In the other crystal systems it is improbable that the axial ratios and inter axial angles of a number of crystals of similar chemical constitution would be almost equal unless the crystals were truly isomorphous

An account of the structure of sodium alum and an examination of the relationship between the α, β and γ structures will be published elsewhere

Conductivity of Oils and Waxes

A FEW years ago I detected a curious region of negative temperature coefficient of the conductivity of heavy oils, namely, a rising conductivity with decreasing temperature[1] It occurred in the neighbourhood of the solidifying point A similar phenomenon has recently been observed by W Jackson with paraffin wax[2], just below its melting point The effect is thought to represent probably a characteristic of both oils and waxes, at least of those containing hydrocarbons It seems therefore desirable to put forward a theory to account for it

A transition between the glassy and the crystalline phase in a mixture like oil must extend over a certain range of temperature The conductivity of the oil in this range is therefore that of a two-phase system The experimental curves suggest that the extrapolated conductivity of the glassy phase in the transition region is lower than that of the crystalline phase Consequently the region of negative temperature coefficient may easily be explained by progressive crystallisation with decreasing temperature This theory also accounts for the dielectric absorption which is always very pronounced in the melting region

Assuming the theory to be correct, it is possible to calculate from experimental conductivity curves, obtained with special oils and waxes, the melting curve, the latter yielding the relative amounts of components of given 'melting point' This curve permits certain conclusions to be drawn as to the approximate chemical composition of the oil, provided its basic nature is known

This work has been carried out for the British Electrical and Allied Industries Research Association, and will probably be published in detail in due course

Raman Spectrum of Trideuter-Acetic Deuteracid

AN account of the preparation of trideuteracetic deuteracid (CD_3CO_2D) by one of us (C. L. W.) will appear shortly in the *Journal of the Chemical Society*. Its Raman spectrum has been examined and gives preliminary results of great interest. The spectrum was obtained from 1.5 c.c. of the substance exposed for 23½ hours to excitation from a mercury arc filtered to transmit only the 4358 A. line.

Displacement	*a*	*b*	*c*	*d*	*e*	*f*	*g*	*h*
CH_3CO_2H	447	621	895	1360	1430	1666	2942	3022
CD_3CO_2D	411	580	800	1025	1093	1657	2150	2218

In the accompanying table, the Raman displacements observed are compared with definitely established displacements for acetic acid. All the displacements of CH_3CO_2H, except *f*, are modified to lower wave number values, but since this frequency is attributable to an inner vibration of the CO_2H group, no change in its value is to be expected. The displacements *g* and *h* most probably have their origin in the C-H link, and preliminary calculations of the expected modification give results in good agreement with the observed values. It is possible that one of these displacements arises from an O-H link, but definite proof of this will be obtained, we hope, by an examination of the spectrum of acetic deuteracid (CH_3CO_2D). The examination of CH_3CO_2D will also give valuable information regarding the other displacements. At present, the origin of these is a little uncertain. Most probably *a* and *b* are associated with bending frequencies of a C-C or C-O link; from intensity considerations, *c* almost certainly belongs to the C-C link; whilst *d* and *e* may arise from the CH_3 or CO_2H groups, and it is hoped this will be decided by the proposed investigation of CH_3CO_2D.

Work is proceeding on CH_3CO_2H prepared by the same method and measured by the same technique, partly to obtain comparable experimental data and partly to clear up certain points on which there is not complete concordance in the results of previous investigators.

The complete results for the three acids and a discussion of the origin of the frequencies will be published elsewhere as soon as the investigation is finished.

Infra-Red Absorption Spectrum of Crystalline Sodium Nitrite

THERE are very few data available in the infra-red absorption spectra of solids which enable an application of the modern ideas of point group symmetry to the classification of 'proper' vibrations. We have recently examined the absorption spectrum of sodium nitrite in the solid state. The substance has already been shown to be orthorhombic, and thus biaxial, with considerable separation between the indices of refraction. There are two molecules in the unit cell, and there will be eight particles in the basic group; accordingly we shall expect $3(8 - 1) = 21$ 'proper' vibrations, of which six will be 'inner' vibrations, and fifteen 'external' or lattice vibrations. Generally, some of the inner vibrations will coincide in pairs, but if the nitrite group is angular, its symmetry will be C_{2v}, which is the same as that of the crystal group[1], and we may expect considerable separation between the pairs. These conditions do not occur in the free ion, and A. Langseth and E. Walles[2] have obtained a clear and satisfying Raman spectrum for the aqueous solution with $\nu_1 = 1331$, $\nu_3 = 1240$, $\nu_2 = 813$ cm^{-1}. In our case all the fundamental frequencies and overtones are doubled, bands occurring at $\nu_2 = 707$ and 834 (10), $\nu_3 = 1127, 1220$ (14), $\nu_1 = 1330$ and 1392 (10), $2\nu_2 = 1378, 1626$ (4), $2\nu_3 = 2252, 2439$ (2), $2\nu_1 = 2646, 2762$ (3). The numbers in brackets give an approximate measure of the relative intensities. The bands at 707 cm^{-1} and 834 cm^{-1} have faint wings on each side, which may perhaps be explained by the trichroism of the substance.

Dr. W. R. Angus and Mr. A. H. Leckie of this Department have kindly examined the Raman spectrum of the solid. They find a broad band in the region of 1350 cm^{-1} with a strong sharp maximum at 1314 cm^{-1}, a weak indication at 1352 cm^{-1}, and a weak but sharp peak at 1400 cm^{-1}. We are continuing the infra-red analysis with polarised light.

Ziegler suggested a vertical angle of some 132°, but our results are in agreement with those of Langseth and Walles, since the frequencies satisfy a central force system with an angle of 96°. There seems to be a single bond between the nitrogen and each oxygen atom, whereas the binding in the nitro-group is of the same type as in SO_2, corresponding to a vertical angle of some 120°.

A New Emission Spectrum in Selenium Vapour

IN the course of a systematic study of the excitation of selenium vapour in a high frequency discharge, we have observed, on the short wave side of the main $^1\Sigma-^1\Sigma$ system[1], a new system of about forty weak and diffuse bands degraded to the red which may be approximately represented by the following formula:

$$\nu = 29{,}890 + 285\,n' - 3\,n'^2 - 390\,n''$$

These bands appear at low temperatures, before the main system becomes visible; but when the temperature is raised, the main system becomes incomparably more intensified than the new one.

The similarity of the vibrational structure of the new system to the main one[2],

$$\nu = 25{,}905 + 281{\cdot}3\,n' - 2{\cdot}42\,n'^2 - 387{\cdot}2\,n'' + 0{\cdot}63\,n''^2,$$

together with the conditions of the excitation and their appearance (large structureless bands) make it plausible that the new system is to be attributed to the excitation of the Se_2 group in a polyatomic molecule of selenium. This seems to be confirmed by the fact that a set of absorption

bands observed by Moraczewska[3] in selenium, at a temperature at which its vapour is certainly polyatomic, represents the continuation of our $v''=0$ sequence. A further study of this system promises interesting conclusions as to the binding energy and structure of such polyatomic molecules, of which little is known.

A full account of our investigations will be published in the *Bull. Acad. roy. Belgique*.

Suggested Polarisation of Electrons

G. P. THOMSON[1] has investigated the peculiar form of asymmetry in the scattering of electrons reported by Rupp[2]. According to Rupp, fast electrons when scattered first by gold through 90° and then passed through a gold foil show asymmetrical diffraction rings, while Thomson could not find any asymmetry up to the voltage of 160 k.v.

We have repeated these experiments, extending the voltage up to 190 k.v., but no effect was found. As in Rupp's experiments, a thick target was used for the first scatterer. Special precautions were made to prevent the non-uniformity of backgrounds; photometric as well as visual comparisons were made on rings up to $\sqrt{35}$ and $\sqrt{36}$. Eight plates were obtained at voltage ranging from 150 to 190 k.v., but none of them showed any asymmetry such as reported by Rupp.

Magnetron Oscillations

IN recent issues of NATURE[1], a discussion took place between us regarding the short wave oscillations produced by split-anode magnetron valves. After further discussion in private correspondence, we are now agreed on the following points:

(1) The oscillations observed by Posthumus[2] in 2- and 4-anode magnetron circuits with wave-lengths of the order of 1 metre appear, on the experimental evidence, to be of the same type as those previously observed by Megaw[3] and others in 2-anode magnetron circuits with similar wave-lengths. The original difference of opinion on this point arose through the emphasis laid on the static negative resistance characteristics in Megaw's explanation of these oscillations.

(2) Static negative resistance characteristics ('dynatron' characteristics) can be observed in both 2- and 4-anode magnetrons under suitable experimental conditions. With usual valve dimensions, these characteristics enable oscillations to be maintained only in circuits of rather low decrement.

(3) At very short wave-lengths, the effect of electron inertia on the dynamic characteristics is such that the term 'dynatron' applied to these oscillations by Megaw is probably a misnomer. At such wave-lengths the maintenance of oscillations appears to depend on the final energies of the electrons, which may be less than the energy corresponding to the anode voltage, rather than on the angles traversed by the electrons during their transit, which determine the static 'dynatron' characteristics. This conclusion follows from the success of the 'rotating field theory' of Posthumus[4] in predicting the relation between optimum wave-length range, anode voltage and magnetic field strength.

(4) It appears from recent experiments carried out by Megaw that there is no discontinuity between the short wave oscillations under discussion and the longer wave oscillations, which are adequately explained by the negative resistance characteristics, when the decrement of the oscillatory circuit is sufficiently low. With circuits of higher decrement, discontinuities may be observed due to the decrease in valve impedance which may occur when the oscillation period is comparable with the electron transit time, particularly when higher modes of oscillation of the circuit are readily excited.

Dew Ponds

THE legend that dew has anything particular to do with 'dew ponds' seems to die very hard. The essence of a dew pond surely is that it should be watertight, which those who make them seem to know quite well. Except in very abnormal years such as 1921 (and I suppose 1933 and perhaps 1934, though I have not seen the figures) the rainfall in England for the year largely exceeds the loss by evaporation from a water surface, and in an average year an empty watertight pond will have accumulated about 5 inches of water from January 1 to the end of April, will lose 2 inches during the next three months and will then progressively become deeper until at the end of the year it has 11 inches. Evaporation averages about 15 inches and never exceeds 20 inches, so that making allowance for the probability that it is a good deal more in exposed ponds than in the relatively sheltered tanks in which it is measured, it would seem that 2 feet of water in the early spring would see any watertight pond safely through any summer. It is also desirable that there should be no standing vegetation, which downland farmers know, though they attribute its bad effect to the roots perforating the floor of the pond rather than to transpiration, which is extraordinarily effective. Last summer (1934) a cement tank in my garden with *Potamogeton crispus* and *Lemna* lost 5 inches of water, while a precisely similar tank a few feet away which had three good clumps of *Alisma plantago* lost 19 inches and went dry.

Mechanism of Feeding in Blood-sucking Diptera

IN a previous communication[1] I reported the discovery of a sucking stylet in ticks which, to all appearances, was the homologue of the hypopharynx in other blood-sucking arthropods On the analogy of the feeding mechanism in ticks, it seemed reasonable to postulate that in biting flies the food channel is not formed by the apposition of the labrum epipharynx and the hypopharynx, as has hitherto been supposed, but that it is represented exclusively by what has until now been regarded as the hypopharyngeal extension of the salivary duct I referred to this tentative conclusion at the meeting of the Royal Entomological Society of London held on October 3, 1934[2] I have now carried out numerous dissections upon freshly killed specimens of *Stomoxys calcitrans*. As will appear from Figs 1 and 2, the labrum-epipharynx in this species of fly is entirely unconnected with the buccal chamber and is practically separated from the hypopharynx by an inward thrust of the apodeme, whilst the buccal chamber itself is continued directly into the expanded proximal portion of the hypopharynx, with the salivary duct terminating distally at this point

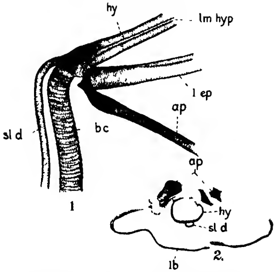

FIG. 1 Buccal chamber and the proximal portion of the mouth parts of *Stomoxys calcitrans* (the labium is not shown) Side view *ap*, apodeme, *b c*, buccal chamber, *hy*, hypopharynx, *l ep*, labrum-epipharynx, *lm hyp*, lumen of hypopharynx, *sl d*, salivary duct × 90

FIG. 2. Transverse section through the mouth-parts of *S calcitrans* at level of articulation of the apodemes *ap*, apodemes, *hy*, hypopharynx, *lb*, labium, *sl.d*, salivary duct × 110

Furthermore, in fresh specimens the hypopharynx is seen to be provided with a distinct orifice at its distal extremity, and its tubular character is shown by the fact that, when the flies are fed on a suitable colouring substance (for example, hæmatoxylin) that has previously been sweetened with sugar, the hypopharynx takes the stain along the entire length of the walls of its lumen, while its external surface retains its normal colour.

Trichromic Vision

THE trichromics, that is those who see three colours in a bright spectrum, red, green and violet, are confused by many with the anomalous trichromatics, whereas they are quite distinct The anomalous trichromatics, as defined by the late Lord Rayleigh, make an anomalous equation and do not agree with the normal equation, and they may not be colour-blind. The trichromics are invariably dangerously colour-blind, and though they may make an anomalous equation they may also agree with the normal equation

The following case will make this clear Examined with Ishihara, read all the figures with the ease and rapidity of a normal sighted person Examined with lantern, called red, white, white, red, green, red, and green, white Tested by colour equations, 10 red, λ633 + 10 green λ540, being the normal equation, matching the light of the arc Made equations ranging from 10 red + 33 green to 10 red + 5 green He also made the normal equation The luminosity in each case was correct Saw three colours in the spectrum red, green, and violet, described λ585 as red mottled, saw green at λ574, named isolated division λ553 5 – λ598 as all green

It will be seen that this case appears both as a high grade red anomaly, a high grade green anomaly and he also made the normal equation It will be noticed that the trichromic in conditions of difficulty, as for example with small lights, make dichromic mistakes

Vitamin and Nitrogenous Food Requirements of the True Lactic Acid Bacteria

IT has now been successfully shown in this laboratory that all the lactic acid bacteria, *Streptococci* as well as rod-shaped forms, demand an alkali stable substance, related to bios, for their growth The rod forms require, in addition to this substance, lactoflavin and possibly still another activator

Earlier research seems to indicate that the true lactic acid bacteria are very fastidious in their requirements as to nitrogenous food Without knowledge of the facts mentioned above, it has been impossible to study this question because the lactic acid bacteria do not grow in a complete mixture of the amino acids present in genuine proteins when activators are absent It has now been found that the *Thermobacteria* show just as narrow requirements as regards nitrogenous food as do the higher animals, and for some species the requirements are even still more specialised On the other hand, the *Streptobacteria* are satisfied with ammonia salts and a trace of cysteine, and the *Streptococci* even with ammonia salts as the sole source of nitrogen

A detailed report will be published shortly.

Origin of Chemistry: the Definition of Flame

IN a recent publication[1] I have shown that practically all the technical achievements on the chemical side which have been credited to the Classical Period, to the Middle Ages, or even (by the least instructed) to our own times, in reality go back to the much earlier civilisations, the crafts of which were largely destroyed by the irruption of the people of the Iron Age, those cruder but better armed ancestors of many of the present inhabitants of Europe

In my further investigations of the development of chemistry proper, which will form the subject of another work to be published before long, the same dependence on earlier periods is abundantly evident An interesting example is provided by the definition of flame Most of the histories of chemistry attribute to van Helmont (1577–1644) the statement that "flame is burning smoke" Kopp[2] (who is probably the origin of their information), however, pointed out in the corrections to his "History of Chemistry" that the statement occurs in Albertus Magnus (1193–1280)[3], which "is notable for its time" It goes back, of course, at least to Aristotle[4], but an interesting link with van Helmont is the statement in Albertus[5], which is also taken from Aristotle, that "flame is burning or ignited *spirit* or smoke" (flamma est spiritus sive fumus succensus sive combustus), in which the approach to van Helmont's definition of gas[6] (hunc spiritum incognitum hactenus, novo nomine *gas* voco) is clear

It is also generally overlooked that Albertus describes[7] the inflammability of intestinal gases, again anticipating van Helmont The work "De Alchimia" attributed to Albertus, from which much of the information as to his contributions to chemistry has been taken by the historians, is clearly much interpolated in the form in which it is printed[8], but parts of it are contained in old manuscripts[9] and parts are also extracts from his authentic works One of the main sources of information on alchemy in Albertus's time was the treatise "De Anima" attributed to Avicenna[10], and practically all the information in European authors was then of Arabic origin If the authorship of a Latin treatise of this time is unknown then, provided it is of a well recognisable type, it may be safely regarded as Arabic Further details will be given in my forthcoming work

Influence of High-Frequency Field on the Combustion of an Acetylene – Air Mixture

THE investigation of the processes of the combustion of gas mixtures in a high-frequency electric field by Haber[1] and later by A Malinowski and ourselves[2] led to the conclusion that the influence of a high-frequency field (10^6 sec^{-1}) in reducing combustion velocity is approximately half that of a constant electric field of the same strength acting under similar conditions

A Malinowski maintains the view that this effect is due to the different efficiencies of the two types of field in removing active centres (ions and electrons) from the combustion zone of the gas mixture

Our further investigations on the dependence of the field frequency and the velocity of combustion have established the fact that increasing field frequency results in a decreasing effect of the field As can be seen from the accompanying table, at sufficiently high frequencies the effect of the field becomes negligible

Electric field (670–700 volt/cm)	Frequency	Decrease of the velocity of combustion (per cent)
Constant	—	9 00
Alternating	1×10^5	6 70
,,	6×10^5	3 37
,,	5×10^6	1 70
,,	8×10^6	0 57

Increasing the frequency of the field further, we discovered an opposite effect, that is, not the diminishing of the velocity of the combustion, but on the contrary its acceleration This effect was observed at a frequency of $1 \cdot 8 \times 10^7$ sec^{-1} Passing into the region of ultra short wave lengths, the acceleration increases and reaches finally 20 per cent at the frequency $3 \cdot 4 \times 10^7$ sec^{-1}

We presume this effect to be due to a sort of resonance energy exchange between the electrons and molecules of a reacting mixture

Twinning in Alpha Iron

ABUNDANT twinning has been observed in pure alpha iron (carbon 0 0022 per cent, silicon 0·0018 per cent) which has been passed slowly through the critical range, and also in pure alpha iron deformed and then recrystallised below the critical range In the former, banded structures are common; in the latter, banded structures are the exception. However, the forms or habits of annealing twins in alpha iron are quite distinctive

Orientation relationships of individual grains were established by means of a back-reflection Laue X-ray method which I have developed The only twin relation observed was of the type ordinarily described as (112) twinning This twinning, considered symmetrically, is, of course, identical with the octahedral twinning commonly observed in metals of the face-centred cubic lattice

It was also observed that the formation of alpha iron upon cooling through the critical range involves

the genesis of macromosaic structure, probably subsequent to the twin formation—analogous to the behaviour of copper upon solidifying. It is believed that the forms assumed by the various constituents in steel, in particular the so-called Widmanstätten figures observed in alpha iron after quenching from above the critical range, are the result of the twinning and macromosaic lattice movements rather than of the crystallographic uniformity of the gamma-to-alpha transformation process, as was proposed by Mehl and Smith.

Results will be published at an early date.

Pyrites in Quartz

PYRITES (FeS_2) in the form of small crystals and specks of a brassy-yellow colour may be found frequently in quartz. Four pieces of Brazilian quartz, containing pyrites inclusions, have now been found which are of unusual interest.

One of these pieces is a well shaped cap of good optical quality, very clear and completely devoid of feathers, 'smoke', etc., and containing three large pyrites crystals and a number of smaller ones. Their colour is almost a pure white and they have the characteristic pentagonal dodecahedron form and striated faces. It is very rarely that such fine inclusions are found in so clear a piece of quartz. The specimen is interesting also in that it has two beautifully etched faces.

A fifth specimen has also been found having a complete hole (approx. 10 × 4 × 8 mm.), in which a crystal doubtless at one time existed, for the faces of the hole are striated corresponding to the structure of the pyrites crystal. Unfortunately, in the process of working the quartz the hole was cut into, so that its vapour content escaped before an examination could be made.

A superficial examination indicates that the inclusions tend to lie in one particular plane through the quartz, and, further, the water inclusions in one of the specimens also lie in the same plane.

A fuller examination of the specimens is now in progress.

The Minimum in the Gamma Function

IT is well known that the gamma function $\Gamma(z)$ for real and positive values of z has a minimum between $z = 1.46$ and 1.47. In a number of texts on the theory of functions it is stated that the minimum occurs at $z = 1.4616321$, and that the corresponding value of $\Gamma(z)$ is 0.8856032. Only one text that we have examined, namely Joseph Edwards's monumental work "Integral Calculus", vol. 2, chap. xxiv (Macmillan, 1922), gives any indication of how the minimum points can be calculated. The method therein explained depends on certain properties of the gamma function and of the related logarithmic derivative $d \ln \Gamma(z+1)/dz$, commonly written $\psi(z)$, following Gauss. At best, the problem is finally one in successive approximation.

There is another approach to the problem, admittedly crude, but effective. Gauss ("Werke", 3, 161–162) left us a table of $\log \Gamma(z+1)$ to twenty decimals, and a table of its logarithmic derivative, $\psi(z)$, to eighteen decimals, by steps of 0.01 in the argument z between $z = 0$ and 1. It should be possible, then, by inverse interpolation in Gauss's table to find the value of z for which $\psi(z)$ vanishes. This value of z will be the abscissa of the minimum in $\Gamma(z+1)$, so that again by interpolation it should be possible to find the minimum value of $\log \Gamma(z+1)$. Finally, by Thompson's twenty place logarithms ("Tracts for Computers", No. 14, Cambridge, 1927) the minimum in $\Gamma(z)$ itself can be determined.

Using Everett's interpolation formula, and retaining sixth differences, we have in this manner found that the zero of $\psi(z)$, and hence the minimum in $\log \Gamma(z)$ and in $\Gamma(z)$ occurs at $z = 1.46163\ 21449\ 68362\ 268$. Interpolation with the same formula gives the minimum of $\log \Gamma(z)$ equal to $\bar{1}.94723\ 91743\ 93385\ 26292$, whence, by Thompson's logarithms, it turns out that the minimum of $\Gamma(z)$ is $0.88560\ 31944\ 10888\ 68870$. In all of these values there is the usual likelihood of an error of a unit or so in the terminal digit.

It is interesting to notice that since we are here dealing with an extreme value of the gamma function, the value of $\Gamma(z)$ at the minimum is relatively insensitive to changes in z; hence, though it is not possible to determine z to more than eighteen decimals—the extent of Gauss's table of $\psi(z)$—the limit of accuracy in determining $\log \Gamma(z)$ is not z, but is Gauss's table of $\log \Gamma(z+1)$. Hence, our values of $\log \Gamma(z)$ and $\Gamma(z)$ should be correct except for the possibility of errors in the twentieth decimal, as mentioned above. As an illustration of this principle, it might be added that a change in z of one unit in the eleventh decimal place produces a change in $\log \Gamma(z)$ of a unit or so in the fifteenth place.

Light-Waves as Units of Length

I WISH to correct an error that occurs in my article on this subject in NATURE of March 30 (p. 496). The mean value of the wave-length of red cadmium in normal air from this table should be $6438.4691 \times 10^{-10}$ metres, and not $6438.4687 \times 10^{-10}$ metres, which is the mean of the last three determinations.

Originally I considered that only these later results should be used on account of the uncertainty, in the earlier work, regarding the carbon dioxide content of the air. Further consideration at the proof-reading stage led me to include the determination of Benoit, Fabry and Perot, in view of the probability that the actual lengths of the international substandards, No. 26 and T_3, were known to a greater accuracy with reference to the prototype metre than was the case with the various national standards. The correction was made in the proof, but the revised value for the mean was not inserted. The vacuum wave-length given at the end of the article was derived from this revised value, and therefore needs no alteration.

Points from Foregoing Letters

EXPERIMENTS with silver bombarded by neutrons and surrounded by air, water and liquid hydrogen, lead Prof J C McLennan, Prof E F Burton and Mr A Pitt to suggest that the radioactivity induced in silver is probably not affected by changes in temperature Dr P B Moon and Mr J R Tillman find, on the other hand, that the radioactivity of silver, rhodium and iodine bombarded by neutrons which have traversed paraffin wax cooled with liquid oxygen, is appreciably different from the radioactivity obtained at ordinary temperature, being greater in the case of silver and rhodium and smaller in the case of hydrogen

From the change in artificial radioactivity produced in spherical detectors of aluminium, silicon and phosphorus by neutrons slowed down after passing through heavy water, as compared with the effect produced after passing through ordinary water, Messrs C H Collie, J H E Griffiths and L Szilard deduce that neutrons suffer a greater decrease in velocity on collision with nuclei of light hydrogen atoms (protons) than on colliding with the nuclei of heavy hydrogen atoms (diplons or deutons)

A 'decay curve' of silver activated by neutrons, slowed down by passage through paraffin, cannot be expressed as a single exponential curve, according to Seishi Kikuchi, Shigeo Nakagawa and Hiroo Aoki They suggest as one possible explanation of results obtained by Bjerge and Westcott that, within certain limits, the yield of radioactive material decreases as the velocity of the exciting neutrons decreases, but below a certain velocity an increase in the yield takes place

Dr C Hurst supports Klemperer's view that the natural radioactivity of potassium is due to a hitherto undetected isotope of mass 40 He calculates that a nuclear spin of only 2 or 3 units (instead of the 4 or 5 units postulated by Klemperer), would be sufficient to account for the slow period of decay

The fact that both neutrons and positive electrons are emitted by lithium bombarded with α-particles leads Mr H J Walke to expect that protons would also be given off Delayed emission of 'negative' electrons should be observed from lithium and boron when bombarded by α-particles

A supraconducting galvanometer has been constructed by Prof E F Burton and Messrs H Grayson Smith and F. G A Tarr They describe some experiments carried out with it, and indicate further fields of research in which the instrument would be useful

From the percentage incidence of certain hereditary diseases (hæmophilia and epiloia), which have a high mortality ratio, Dr L S Penrose and Prof J B S Haldane calculate that such diseases must arise as mutations, with a frequency of about 1 in 100,000

Dr. Kenneth Smith directs the attention of horticulturists to the appearance of a new virus disease attacking tomato plants, and describes the symptoms which characterise the new disease

Miss D. A E Garrod and Miss E W Gardner report the finding near Mount Karno, Palestine, of flint implements in a layer of red earth within a deposit of wind-blown sandstone, hitherto thought to be a marine formation of Pliocene age The implements are of Mousterian and Levallois type and the deposits in which they are found must belong to the late Pleistocene, a fact which is likely to lead to the revision of some of the current views concerning the age of other geological formations in Palestine

The molecular polarisation of phenol in benzene has been measured from the dielectric constant and the density of its solutions by Dr A R Martin He finds that as the concentration is increased the molecular polarisation increases and then decreases, as it does in the case of the lower alcohols

In the breakdown of sugar by fermenting peas, combination of the sugar with phosphoric acid appears to be a necessary step, according to experiments reported by Mr M S Rao In this respect, chemical reactions in higher plants seem to be similar to those in animal muscle

Mr S H. Clarke points out that the crushing strength of ash timber when compressed parallel to the grain is roughly indicated by the colour that the wood stains with phloroglucin and hydrochloric acid In strong specimens the fibre-walls stain red and in weaker types the middle lamella region stains a faint pink The test has been used to detect weakness in hockey sticks

In view of the fact that X-ray analysis shows potassium, cæsium and methyl-ammonium alums, previously considered isomorphous, to have in reality different structures, Mr H Lipson raises the question whether similar differences of structure may not exist in other supposedly isomorphous series He concludes that such pseudo isomorphism is only likely to occur in crystals of the cubic system.

The electrical conductivity of heavy oils and of paraffin wax, in the neighbourhood of melting point, rises with decreasing temperature This abnormal behaviour, Dr A Gemant suggests, may be due to progressive crystallisation with decreasing temperature, the substances considered behaving as two phase systems

The spectra of light scattered by ordinary acetic acid and by the corresponding compound containing heavy hydrogen, have been investigated by Messrs W R Angus, A H Leckie and C L Wilson From the displacement observed in some of the spectrum lines, they tentatively connect those lines with the known valency links between atoms (C—H, O · H, C—C, C—O)

The absorption of infra-red light by crystalline sodium nitrite has been determined by Messrs C R Bailey and J W Thompson Its relation to the light scattered by sodium nitrite crystals and solution gives an indication of the arrangement of the atoms and the molecular forces involved

A high frequency discharge through selenium vapour has yielded light attributed by Messrs B. Rosen and M Désirant to the excitation of the Se_2 group in the polyatomic molecules of selenium.

The effect of a high-frequency electric field upon the combustion rate of a mixture of acetylene and air is reported by Messrs W Rossichin and W Timkowski They find that an increase in frequency between 10^2 and 10^7 sec $^{-1}$ causes a decrease in the velocity of combustion, but with higher frequencies the effect is reversed

News and Views

Prof Graham Kerr and Parliamentary Representation

THE appointment of Mr John Buchan as Governor General of Canada necessitates a by election for a representative of the Scottish universities in the House of Commons We are very glad to see that Prof J. Graham Kerr, regius professor of zoology in the University of Glasgow, has been adopted as a candidate by the Unionist Association of the Universities of Edinburgh, Glasgow, Aberdeen and St Andrews It would be difficult to find a man of science who could more worthily represent the Scottish universities in Parliament than Prof Kerr He combines long experience of the teaching and administrative sides of these universities with wide scientific interests and a high position in the political field, being president of the Scottish Unionist Association, chairman of the Glasgow Unionist Association, and holding similar offices in other Unionist organisations Prof Kerr's election to Parliament would involve considerable self-sacrifice, for it would mean the giving up of the life tenure of his chair of regius professor of zoology in the University of Glasgow In these days, when the whole of our communal existence is permeated by science and its applications, it is the duty of scientific workers to take an active part in shaping the destinies of the nation by promoting the election into the House of Commons of representatives having scientific knowledge and outlook At present there is not a single fellow of the Royal Society in the House of Commons, and if, as we hope and expect, the Scottish universities return Prof Graham Kerr as their member, they will be rendering a notable service to science and the nation

Ergometrine, a New Alkaloid from Ergot

THE clinical observations of Moir (*Brit. Med J*, i, 1119, 1932), that aqueous extracts of ergot are more effective in producing the uterine contractions to which this drug owes its medicinal use than are any of the known ergot alkaloids, for example, ergotinine, ergotoxine, ergotamine, has recently led to the isolation by H W Dudley and C Moir (*Brit Med J*, March 16, 1935) of a new ergot alkaloid which promises to become of great importance in obstetric practice The new alkaloid, termed ergometrine, is a crystalline, water soluble base, of which 0·82 gm was obtained from 10 kgm of defatted ergot Oral administration of ergometrine, in a dose of 0·5–1·0 mgm, produces strong uterine contractions after 6½–8 minutes By way of contrast, doses as large as 2–3 mgm of ergotoxine and ergotamine, given by mouth, have a relatively feeble oxytocic effect after an interval of 35 minutes or more, and a similar type of activity is shown by the recently discovered ergot alkaloids, sensibamine and ergoclavine. Even when given by injection, the ergotoxine-ergotamine alkaloids are rather slow in action, and often produce such unpleasant symptoms as headaches, nausea and depression Ergometrine is stated to be free from these undesirable subsidiary effects.

A SAMPLE tube has been sent to us of ergometrine as manufactured in the laboratories of British Drug Houses, Ltd, and supplied in tablets containing 0 5 mgm, suitable for oral administration It is astonishing that the recognition of this active principle of ergot should have been so long delayed, and it may be that even more valuable secrets will ultimately be disclosed by this remarkable parasitic mould, the investigation of which has already yielded ergosterol and its irradiation products, including artificial vitamin D Further reports on the pharmacology and chemistry of ergometrine will be awaited with considerable interest In the issue of the *Lancet* of May 25 (p 1243), M S Kharasch and R R Legault discuss the possibility that ergometrine may be identical with, or closely related to, the ergotocine recently isolated by these workers and their collaborators (*Amer J Obst and Gyn*, February, 1935, p 155) Pure crystalline ergotocine is being manufactured in large quantities by the Eli Lilly Company, the recommended clinical dose for oral administration being 0·4 mgm

Prof P. Lenard of the University of Heidelberg

THE Physical Institute of the University of Heidelberg has recently, in honour of Prof Lenard, been renamed the 'Philipp Lenard Institut' A correspondent has sent us a cutting from the students' magazine of that University, giving Prof Lenard's reply to the congratulations of the Heidelberg students on this occasion The following is a translation of Prof Lenard's reply, and we prefer to make no comment upon it —"I am very grateful to the students of the University of Heidelberg for their congratulations on the renaming, by the Ministry, of the Institute which was built some years ago under my direction I hope that the Institute may stand as a battle flag against the Asiatic Spirit in Science Our Leader has eliminated this same spirit in politics and national economy—where it is known as Marxism In natural science, however, with the over-emphasis of Einstein, it still holds sway We must recognise that it is unworthy of a German,—and indeed only harmful to him—to be the intellectual follower of a Jew Natural science properly so called is of completely Aryan origin and Germans must to day also find their own way out into the unknown. Heil, Hitler!"

Rationalisation of Scientific Publication

A POINT raised in the leading article in NATURE of March 9 on the subject of "Rationalisation of Scientific Publication", relating to the duplication of abstracts, led Dr Ainsworth Mitchell to state the views of the Society of Public Analysts in a letter published in our issue of May 11, p 791 Further communications have since reached us from other members of the Society. The main contention is that the Society produces at its own cost something for the use of its members which is not supplied by

the British Chemical Abstracts; and that these specialised abstracts are widely appreciated. In so far as a large number of members of the Society of Public Analysts are members also of one or both of the societies maintaining the Bureau of Chemical Abstracts, no reasonable objection can be raised to this action. None the less, the unprejudiced onlooker may regret the example when overlapping and duplication are still so widely apparent in chemical literature, and when the major scientific societies find the burden of publication a severe tax on their resources. He may still be entitled to conclude that it is idle to deplore such financial limitations or to lament the growing difficulty which besets every scientific worker of keeping abreast of his subject until there is to be found a much greater willingness to make generous sacrifices in the general interest. It is unfortunate that a phrase in the original article, intended merely to indicate the ground covered by the abstracts of the Society of Public Analysts, has been construed to refer to the matter and data of the abstracts in a way which the Society would have been justly entitled to resent. Such criticism of any society is, however, most effectively disarmed by the measure in which the Society publicly as well as privately supports the central institutions for the co-ordination of scientific literature in the particular science it avows.

Export of Antiquities from Egypt

A REPORT from Cairo points to the possibility of further restrictions on the export of antiquities from Egypt. Under the existing antiquities law, which has been in operation for a little more than a decade, the rights of the State in the allocation of the proceeds of legitimate excavation have been well—indeed some would say too well—protected, but it has proved difficult to check clandestine digging. The finds from these illicit activities frequently, but not invariably, find a final resting place in the Cairo museum, but a considerable number still are smuggled out of the country. According to a dispatch from the Cairo correspondent of *The Times* in the issue of May 25, violent protest has been raised in the Arab newspapers as a result of reports of the value of papyri, and especially of the new fragments of a Gospel now in the British Museum, which have been sold at high prices to European collections. Inquiries by *The Times* correspondent have elicited the admission that sales by Cairo dealers to private collectors have been due to the fact that the Cairo Museum has not shown an interest in papyri except when of historical importance. As a consequence of this agitation, however, the Minister of Education, Nequid Bey Hilali, has appointed a committee to inquire into the question of illicit sales of antiquities. Although archæologists may sometimes have felt the burden of the regulations imposed upon legitimate excavation to be unduly irksome, they will have no quarrel with any measure checking that destruction of scientific evidence which is the inevitable accompaniment of clandestine digging and illicit sales.

Control of Architecture

THOUGH a nation may not be judged wholly by its architecture, this at least forms an outward and visible sign of its mentality, and since many buildings outlive a number of generations, it is our duty to posterity to see that the structures we erect are not only fitted for their purposes, but also are outwardly gracious and in harmony with their surroundings. Great developments in building are in progress, municipal, institutional, commercial and most of all domestic owing to the programmes of slum clearance. These developments merit the employment of only qualified architects, to ensure the greatest economy in the expenditure of money and the most suitable results in design which proper training can alone give. The Royal Institute of British Architects sent last January to the Minister of Health a memorial expressing the readiness of the architectural profession to give assistance in the matter of slum clearance schemes, and pointing out that many of the local authority staffs have neither the time nor the experience to deal adequately with these large problems. Most people will admit the wisdom of employing a properly qualified professional man for any service, be it medical, legal or architectural, and the suggestion that public money should only be spent under competent professional advice appears to be sound reasoning. A great deal of time is given gratuitously by architects in serving on panels to assist in the improvement of designs submitted to local authorities, and through a very complete system of professional education the advice and service of competent men is now obtainable in all parts of the country.

Recent Acquisitions at the British Museum (Natural History)

OF all the regions of the world, the Pacific coast of South America is, perhaps, the most poorly represented in the Museum collection of fishes, and a representative series of the marine fishes of Chile has long been required. Through the kindness of Mr. V. Cavendish-Bentinck, of the British Embassy at Santiago, arrangements have been made with the Chilean fisheries authorities to supply the Department of Zoology with well-preserved specimens of the more important fishes. The first consignment of what promises to be a collection of considerable importance has now been received, and another consisting of specimens collected in the Juan Fernandez Islands is expected within a few weeks. Among the specimens acquired by exchange for the Zoological Department are examples of the Hawaiian land snail *Achatinella*. The species and races of these snails, which are often restricted to single ridges and ravines (in some cases even to single trees), are classical examples of the effects of isolation in species-formation. The Department of Mineralogy has acquired by purchase a remarkable set of 98 meteoric stones which fell in 1869 as a shower at Tenham station, Kyabra County, South-West Queensland, and are as yet undescribed. Another purchase is a fine doubly-terminated crystal of ruby and a faceted colourless chrysoberyl (7·15 carats) from the ruby

mines at Mogok, Upper Burma Chrysoberyl is usually of pronounced colours, the variety alexandrite, for example, being green by daylight and red by lamp-light, and a colourless gem of this species has not previously been recorded

THE Department of Botany has received more than 2,900 numbers as a result of the British Museum Expedition to East Africa These were collected by Dr. G Taylor, assistant keeper in the Department some additional numbers collected by Mr P M Synge have not yet arrived Four groups of mountains were visited—Aberdare, Beringa, Ruwenzori and Elgon The longest period was spent on Ruwenzori itself, and extensive collections were made in the Namwamba valley up to the snow line the plants from the adjoining Nyamgassani valley, where Mr Synge collected, will afford an interesting floristic comparison Although main attention was paid to the mountains, the flora of the plains was worked so far as possible, and the aquatic flora from the rivers yielded much of interest in relation to researches being carried out in the Department It is not possible to give an analysis of the collection at present, but it contains several new species and a large number of plants not previously represented in the Museum The herbarium of William Rashleigh (1777–1855) was recently purchased from a second-hand bookseller This is entirely of seaweeds and is contained in three volumes. Its main interest is that it contains the herbarium of John Stackhouse (1742–1819) the author of "Nereis Britannica" (1795–1801) in which some of the first post-Linnean genera of algae were published Some years ago, an effort was made to trace the herbarium in order to clear up some points which had arisen regarding nomenclature, but nothing could be learned beyond the fact that it had been bequeathed to Rashleigh. The collection was offered for sale in the ordinary way A small volume of mosses collected by Dr W K. Kane on the U S Grinnell expedition in search of Sir J Franklin (1853–55) has been purchased These were apparently the original set of the "Kane Portfolio" arranged by T P James Most of the cryptogams collected on the expedition were lost when the vessel was abandoned

Linnean Society of London

AT the anniversary meeting of the Linnean Society of London held on May 24, the president, Dr W T. Calman, delivered a presidential address, "The Meaning of Biological Classification" The Linnean Gold Medal was presented to Sir David Prain, a past-president of the Society, in recognition of his services to botany. In making the presentation, Dr Calman mentioned that Sir David began his scientific work as a member of that great service which has produced so many eminent naturalists, the Indian Medical Service, that he became the head of Indian botany when he was superintendent of the Botanical Survey of India and of the Royal Botanical Gardens, Calcutta. When Sir David returned to England, he became director of the Royal Botanic Gardens at Kew, an office which he filled with conspicuous success until his retirement in 1922 But although his success as an administrator has been conspicuous, he has never forgotten that the business of a scientific man is scientific research, and his contributions to systematic botany, particularly that of the Indian Empire, are of a kind that would have gladdened the heart of Linnæus himself The following officers were elected for the year 1935–36 *President*, Dr W T Calman, *Treasurer*, Mr Francis Druce, *Secretaries*, Mr John Ramsbottom (botany), and Dr Stanley Kemp (zoology) The new members of the Council are Dr B Barnes, Mr D J Scourfield, Lieut.-Colonel R B Seymour Sewell, Mr W H Wilkins and Dr E B Worthington The president announced that he had appointed the following vice-presidents Prof G D Hale Carpenter, Mr Francis Druce, Dr Margery Knight and Prof Macgregor Skene

Temperament in Industry

PROF MAJOR GREENWOOD delivered the second of his Heath Clark Lectures, under the auspices of the National Institute of Industrial Psychology, on May 20, on "Temperaments, Physical and Psychological, in Modern Science" He pointed out that the ancient physicians were deeply conscious that differences of temperament entailed psychological consequences which expressed themselves in bodily as well as mental reactions, and that it was the duty of the physician to diagnose and treat these conditions In Great Britain the work of Kretschmer has received considerable attention, but the infinitely clearer and scientifically more rigorous work of Boldrino and the Italian School has been unduly neglected Boldrino has shown that it is probable that certain morphological types, roughly corresponding to the old 'sanguine' and melancholics', do differ in resistance to such diseases as tuberculosis, in distribution through the social classes, and even in fertility, but in respect of psychological characters there is much less evidence of any such relation Prof Greenwood considered the claims of some modern work on temperament that had relied on statistical correlations he emphasised that statistical description is fundamentally group-description only, and has little diagnostic value in individual cases He illustrated this by data on accidents, and showed that, while the application of tests would undoubtedly eliminate many likely to be accident prone, yet they would also eliminate some who are not, and so do an injustice to individuals Although Prof Greenwood feels that, with respect to a finer gradation of temperamental qualities, we are indefinitely far from any fool-proof system of routine testing, yet we may be near to the time when an elimination of extreme variants on a basis of temperamental tests will be practicable

Poisons and their Detection

DR G ROCHE LYNCH delivered the thirtieth Bedson Lecture in Newcastle upon-Tyne on May 16 After a brief outline of the history of poisoning from ancient times up to the beginning of scientific

investigation with Marsh, about a century ago, and Stas in 1850, Dr. Roche Lynch discussed the general characteristics of poisons With the exception of a few of animal origin, like snake venom and certain serums, tolerance toward all poisons increases with repeated small doses; narcotics, alkaloids, metals and even castor oil This seems to be due to growing immunity of the cells as well as to increased rate of excretion or destruction In general, detoxication takes place mainly in the liver with increasing efficiency, the processes seeming to be developments of natural responses Quite large amounts of the heavy metals have been found, lead up to 146 parts per million being demonstrated in normal bone where no industrial or similar causative contact had occurred Difficulty arises with the modern synthetic medicinals, they have often only a narrow margin between the medicinal and the toxic doses and have little allowance for idiosyncrasy Many of them are completely destroyed, or changed in the tissues into something else in a short time The barbituric acid group are particularly dangerous, and should be brought under regulation They are all hypnotics but their behaviour from a toxicological point of view is very different Some of these compounds are almost completely destroyed in the body, so that analysis only reveals a trace, and others are readily found in considerable quantity both in the excreta and in the organs Opinion therefore as to the cause of death must depend on the type of barbiturate present and the amount isolated Dr. Lynch then dealt in greater detail with arsenic, strychnine and carbon monoxide, illustrating his remarks with references to, and exhibits from, famous criminal cases

Conservation of the Flora of Great Britain

IN the report of the work of Flora's League, a society for the preservation of wild flowers, ferns and trees, covering the years 1932–34, the League records its work, in collaboration with other bodies, for the conservation of the British flora, and its plans for the future In co-operation with the Cotteswold Naturalists' Field Club, the Gloucestershire station of *Ranunculus ophioglossifolius*, which grows in this and one other county only in England, has been secured for all time, while in Lancashire special efforts are being made to preserve the endangered flora of the sand-dunes in the vicinity of Ainsdale, the only known habitat of *Epipactis dunensis* Following on the successful re-introduction of *Maianthemum bifolium*, the may lily, in Ken Wood, under the direction of Mr J. S. L Gilmour, assistant director of the Royal Botanic Gardens, Kew, the League has plans for the cultivation of rare species of wild-plants for their seeds, to sow in wild flower gardens or in haunts from which they have disappeared; though record of the site and other details of each such experiment will be reported to the Department of Botany of the British Museum (Natural History) to avoid any confusion of records of field botanists Under the auspices of the Wild Plant Conservation Board of the Council for the Preservation of Rural England, the British Wild Plant Nurseries and Seed Exchange Agency has been originated by Mr. C. S. Garret at Derby, for this purpose, but not to be run as a commercial profit-making concern; while the Green Cross Society and the British Empire Naturalists' Association, affiliated organisations, have similar seed-distributing schemes The president and founder of the League is Sir Maurice Abbot Anderson, and it has offices at the Council for the Preservation of Rural England at 17, Great Marlborough Street, London, W 1

Meteorology in Northern Rhodesia

THE Meteorological Report for Northern Rhodesia for 1931–32 (No. 9) is the first of this series that has appeared since responsibility for the direction of meteorological work in that colony was taken over by the Director of the British East African Meteorological Service (Mr A Walter), for although the new service was officially inaugurated in 1929, it was not until the end of 1931 that Northern Rhodesia was included in it, control being meanwhile in the hands of the Director of Surveys. The new regime began soon after the completion of the Territorial First Order Meteorological Station at Broken Hill—a station exactly similar to the other first order stations already established in Kenya, Tanganyika and Uganda. Before the end of the year, autographic records of temperature, humidity and atmospheric pressure were in operation there, and were used for obtaining the hourly readings of these elements that appear in this report for the six months January–June 1932. The work of Broken Hill includes the distribution of forms and equipment to the subsidiary stations within the colony, the handling of all the records obtained at such stations, and the issuing of weather reports, including the results of pilot balloon ascents, to aeroplanes passing over Northern Rhodesia The report is on the same general lines as the earlier annual reports; it includes, in addition to statistical tables on normal lines, discussions of the separate meteorological elements, among which rainfall, as in the tropics generally, is of the greatest immediate practical importance There is in addition an account of a waterspout that was seen near Nsalushi Island, in the swamp area of Lake Bangweolo, on February 19, 1932, and particulars of slight earth tremors reported from a number of subsidiary climatological stations

Distributing Electricity to Country Districts

DURING the last ten years, the distribution of electricity by means of overhead lines has made rapid progress; but there are still nearly 80 per cent of the occupied rural areas of England where electric supply is not available. There is a vast amount of development work to be done in these areas. Already the capital sunk for distributing power is considerably in excess of that used for generating power. The annual expense in distribution is at the present time three times greater than that for generation The progress already made shows that there is plenty of scope for technical improvements which would increase the factor of safety and lower the cost of

supply. The rural schemes already installed prove that an overhead distribution at 11,000 volts (11 kv.) is economical when the loads are small. When heavier loads are anticipated, 33 kv. is generally adopted. In a paper by R. Dean read to the Institution of Electrical Engineers on May 15, the available data relating to rural design have been collected and the many numerical tables given will enable engineers to obviate many tedious calculations. Official regulations and a number of practical details in design are also given. For rural supply, it has been found that wood poles are the best. Both concrete and steel poles are about 12 per cent more expensive. The admissible factor of safety for wood poles has now been reduced to 3·5. At the time of constructing the 132 kv. grid, steel-cored aluminium was the most popular conductor to use, but the author's tables show that copper-cored steel or steel cored copper provide rather cheaper lines. The requisite experience has not yet been obtained of the effects of electro chemical action on these lines after a number of years exposure to the weather. There are many subsidiary advantages in favour of steel cored aluminium for high-voltage lines.

Prof. Patrick Abercrombie

THE University of Liverpool gave London its first professor of town planning in Prof. S. D. Adshead, who has held the chair of town planning in the Bartlett School of Architecture at University College since 1914. The University of London is fortunate in securing as his successor Prof. Patrick Abercrombie, who since 1915 has been Lever professor of civic design at Liverpool. During these last twenty years he has been engaged in educating town planners, and has himself been a leader in every movement for the improvement and preservation of town and country alike. His interest in planning is not confined to town and industrial areas: he was one of the three mainly concerned in the founding of the Council for the Preservation of Rural England, and his work there has shown the necessity of proceeding by country preservation to country planning, and finally to national planning. He has recently been appointed to prepare the plans for a national park in Snowdonia. The series of town planning schemes published by the University Press of Liverpool, the *Town Planning Review* started in 1910 and issued for the last twenty-five years under his editorship, form a fine written and pictorial record not only of the work of Prof. Abercrombie himself, but also of all those who have devoted themselves to these problems during recent years.

Health of the Army during 1933

LIEUT.-GEN. J. A. HARTIGAN, Director-General of the Army Medical Services, details in his first report, recently issued, the health of the Army at home and abroad for the year 1933 (H.M. Stationery Office. 2s. 6d. net.) The total strength at home and abroad was 184,000 men. The general health of all ranks fell little short of the high level reached in 1932, some increase in the admission rate being almost wholly accounted for by an increase in the incidence of influenza. The chief causes of death were injury, tuberculosis, pneumonia and suicide, and of invaliding, tuberculosis and inflammation of the middle ear. Venereal diseases have again diminished, but tonsillitis still claims a number of victims and has slightly increased. The admissions for diphtheria show a welcome reduction, and it is remarked that at the depots at Caterham and Woolwich, where Schick testing and immunisation when necessary are carried out as a routine, the disease is practically non-existent. In addition to the statistics, details are given of the various measures that are being adopted at home and abroad for the prevention of disease.

Conference on Atmospheric Pollution

THIRTY-SIX representatives of local authorities and other organisations co-operating with the Department of Scientific and Industrial Research in the investigation of atmospheric pollution met on May 27 in the half yearly conference on atmospheric pollution at the offices of the Department. A report was received from Dr. G. M. B. Dobson on the progress of the researches carried out under the Atmospheric Pollution Research Committee. Dr. Dobson informed the conference that a full time investigator has been appointed by the Department as a preliminary to the undertaking of an intensive survey, at a selected centre, of various types of pollution with a larger number of instruments. The method developed at the Building Research Station for estimating sulphur in the atmosphere is now being adopted more widely by the local authorities. Further experiments combined with weather observations are being taken in hand to facilitate the interpretation of the data collected by means of the deposit gauge observations.

Lister Institute of Preventive Medicine

AT the general meeting of the members of the Lister Institute of Preventive Medicine, which was held on May 21, the governing body presented the Institute's forty-first annual report. This report contains an excellent summary of the important research work carried out in the laboratories and Serum Department during the past year. The amount of research seems to be more voluminous than usual, and the list of communications published occupies several pages. With the aid of a grant of £3,400 by the Rockefeller Foundation, a Svedberg velocity and equilibrium centrifuge is to be installed, a new and valuable equipment that should find useful application in protein, virus and other researches.

Czechoslovak Institute for the Study of Sound

AN institute for the study of sound has just been established in Prague under the management of Profs. K. Teige, M. Seemen and V. Vojtěch. The purpose of the institute will be to bring together scientific and practical workers to investigate sound in its physical, technical and physiological aspects. In pursuit of these aims it is proposed to arrange inquiries, excursions, lectures, both scientific and popular, and to carry out experiments and publish the results. The first important step to be taken in this connexion will be the equipment of a research

laboratory, and one of the first tasks of the institute will be to investigate noise and the methods of dealing with it. Another subject for early inquiry will be the technique of musical instruments

Announcements

THE Langley Medal for aerodromics of the Smithsonian Institution was presented on May 21 to Dr Joseph S Ames, of Johns Hopkins University, who is chairman of the National Advisory Committee for Aeronautics The award was made "in recognition of the surpassing improvement of the performance, efficiency, and safety of American aircraft resulting from the fundamental scientific researches conducted by the National Advisory Committee for Aeronautics under the leadership of Dr Ames"

THE Executive Council of the Universities Bureau of the British Empire has had before it nine nominations from Conferences of Universities overseas for the Carnegie Corporation Grants to the value of £400 each for the year 1935-36 A Selection Committee scrutinised these nominations and on May 25 the Executive Council approved the decision of this Committee to award these grants to Prof T J Haarhoff, of the University of the Witwatersrand, Prof T H Laby, of the University of Melbourne and Prof Meghnad Saha, of the University of Allahabad

THE curators of the Dr Martini fund have awarded the 1935 prize of 1,000 gold marks to Dr Carl, a former assistant at the Friedrichberg State Hospital, and at present senior physician in the serological and bacteriological department of the hospital, for a work on adenylacid metabolism in normal persons and the insane and in the brain of animals

THE annual visitation of the National Physical Laboratory, Teddington, Middlesex, will take place on Tuesday, June 25, at 3–6 p m

AT the annual general meeting of the British Science Guild, to be held on June 12 at 4 30 p m, a lecture on "Gas Defence" will be given by Mr J Davidson Pratt, general manager and secretary of the Association of British Chemical Manufacturers The meeting will take place in the lecture theatre of the Royal Society of Arts, John Street, Adelphi, London, W C 2, and tickets (for which there is no charge) may be obtained on application to the Secretary of the British Science Guild, 6 John Street, Adelphi, London, W C 2

THE fourteenth annual congress known as the Journeés médicales de Bruxelles will be held at Brussels from June 29–July 3, that is, while the International Exhibition is still open The inaugural address will be delivered by Prof Loeper, of Paris, on music and medicine. The subscription is 100 francs. Further information can be obtained from the general secretary, Dr. René Beckers, 141 rue Belliard, Brussels.

MESSRS. WHELDON AND WESLEY have recently issued Catalogue No. 40 of books, periodicals and pamphlets on geology, palæontology, mineralogy and mining Upwards of 1,300 items are listed, including many older works of historical interest Among the periodicals may be mentioned an exceptionally long run of the *Annales des Mines*, from its commencement in 1795 (as the *Journal des Mines*) down to 1918 There is also listed a large number of the *Memoirs of the Geological Survey* of Great Britain, and of the bulletins and monographs of the United States Geological Survey. The pamphlets include many extracted from early volumes of the *Philosophical Transactions of the Royal Society*

APPLICATIONS are invited for the following appointments, on or before the dates mentioned :—An engineer at the Building Research Station, Garston, near Watford—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S W 1 (June 4) A lecturer in mechanical engineering in the St Helens Municipal Technical School—The Secretary for Education, Education Office, St Helens (June 7). A temporary demonstrator in botany in the University College of Wales, Aberystwyth—The Secretary (June 8) A lecturer in mining in the Heanor Mining and Technical School—W G Briggs, Director of Education, Derby (June 8) A lecturer in mathematics in Merchant Venturers' Technical College, Bristol—The Registrar (June 11) A junior in the Records Section of the Fuel Research Station, East Greenwich—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S.W 1 (June 11) A lecturer in the Department of Civil and Mechanical Engineering, King's College, Strand, London, W C 2—The Secretary (June 12) A woman lecturer in biology and the teaching of biology in the Department of Education, University of Birmingham—The Secretary (June 13) A lecturer in mathematics, a lecturer in science and a lecturer in general education at the Royal Military Academy, Woolwich—The Under-Secretary of State (C 5), The War Office, London, S W.1 (June 15). A lecturer in mathematics, a lecturer in botany and a lecturer in physiology in the Chelsea Polytechnic, London, S.W.3—The Principal (June 15). A Curator of the Public Museum and Art Gallery, Hastings—The Director of Education, 18 Wellington Square, Hastings (June 15) A lecturer in physics and mathematics in the Northampton Polytechnic, St. John Street, London, E.C.1—The Principal (June 21). A lecturer in botany at the Imperial College of Science and Technology, London, S W 7—The Secretary (June 22). An assistant lecturer in chemistry in the University of Sheffield—The Registrar (June 22). A lecturer in electrical engineering at Loughborough College—The Registrar (June 30). Two University demonstrators in pathology in the University of Cambridge—Prof. H R. Dean (July 10). A part-time demonstrator in chemistry in the London (Royal Free Hospital) School of Medicine for Women —The Warden, 8 Hunter Street, Brunswick Square, W.C.1. A lecturer in civil engineering and building in the Portsmouth Municipal College—The Registrar.

Research Items

Human Skeletons at Hythe. The skulls and long bones preserved in the ossuary of the church of St Leonard at Hythe, which were examined by Prof F. G. Parsons nearly thirty years ago, have been subjected to further study by Dr G M Morant and Miss Stoessiger As a supplement to their report, which appeared in *Biometrika*, **24**, 1932, Dr Morant has now published a general account of the origin, history and character of the collection so far as his research has carried him ("The History of the Human Skeletons preserved in the Ossuary of the Church of St Leonard, Hythe." F J Parsons, Ltd Pp 41. 1*s* 6*d*) The place of their storage is neither crypt nor charnel-house, but a passage way under the chancel, made when the church was enlarged in the early thirteenth century, to serve as part of the processional path On the basis of the thigh-bones, the number of individuals represented is at least 4,000. Popular tradition attributes them to those slain in a battle fought in 456 A D between Britons and Saxons, or to Danes who landed in 843, or to French who raided the coast in 1295 An examination of the bones shows that they consist of an almost equal number of male and female and vary widely in range of age, children alone not being present It is concluded that they are the remains of inhabitants of the parish, extending over a considerable period of time, placed in the church for safe keeping after inhumation Anthropologically they present peculiar characteristics, for which the only known parallel in the British Isles is found in the skeletal remains of indeterminate age from Spitalfields in London, which were brought to light at the extension of the Fruit Market in 1926 This Spitalfields series bears a close resemblance to a series from Pompeii and to another of Etruscans of the Roman period from north Italy Not only does the Hythe type resemble that of Spitalfields closely, but it is also closely allied to modern series from Bologna, Czechoslovakia and Rumania The Spitalfields people were probably Roman inhabitants of London of Italian origin and it is, therefore, probable that the Hythe people are descendants of foreigners who settled in the locality in Roman times

Protective Habit of Desert Kangaroo Rat. Seth B Benson has observed that a desert kangaroo rat (*Dipodomys deserti*) brought into the neighbourhood of objects which it regarded with suspicion, kicked considerable volumes of sand upon them, apparently with the view of discovering whether they were alive (*J. Mamm.*, **16**, 67; 1935). During a period of about five minutes, it skirmished in front of the objects (in this case a pile of bread crusts), and the skirmish ended with the rat turning about, kicking sand upon the pile with force and precision by using its hind legs, and immediately whirling about to watch the effect of its storming. This action was repeated half a dozen times It explained why the author had previously found many of his small mammal traps set off and partially buried in the sand, because the amount of sand thrown and the force with which it was thrown were enough to effect these results. The suggestion is that this action is a defensive action likely to be of particular value against such an enemy as the sidewinder snake (*Crotalus cerastes*), which inhabits desert places and is known to feed upon kangaroo rats.

Researches upon the Tubercle Bacillus. Konrad E Birkhaug describes in two lengthy papers observations upon the general characters of several strains of the tubercle bacillus (*Ann de l'Institut Pasteur*, **54**, No 1, p 19, No 2, p 195, 1935) Avian, bovine and human strains show little difference in morphological characters, but are liable to dissociate spontaneously into three types of colonies, the *Ch* (chromogenic), *R* (rough), and *S* (smooth) For the avian strain, the *S* variety is the dominant type, and *Ch* and *R* varieties are relatively rare For the mammalian strains, the dominant type is the *R* variety, and the *S* and *Ch* varieties are rarer These varieties are not stable, but frequently change one into another both *in vivo* and *in vitro* The *Ch* and *S* varieties develop at laboratory temperature (20°-30° C), but the *R* variety develops only at 37°-40° C, none of them develops anaerobically The *R* varieties of the avian and mammalian strains are more resistant to dyes and disinfectants than the *Ch* and *S* varieties, but the latter are more resistant to heat and light than the former. The *Ch* variety of both avian and mammalian strains are generally avirulent to animals

A Brown Rot Fungus. The brown rot fungi of tree fruits have received considerable attention of late years Various species of the genus *Sclerotinia* are the chief causal fungi, but a brown-spored discomycete, *Lambertella Corni-maris*, has recently been found to produce brown rot symptoms upon a variety of fruits and vegetables (T H Harrison and A F Helaly, *Trans. Brit Mycol Soc*, **19**, Part 3, 199–214, February 1935) Dr Harrison made a tour of some of the fruit areas of western Europe in 1931, and found apothecia of a fungus upon mummified pears in Switzerland and south Germany They seemed to be characteristic of *Sclerotinia cinerea*, but were identified by Mr S P Wiltshire as the fungus named above Dr El-Helaly made cultural studies of the fungus, which tolerates a wide range of acidity, and produces fruit bodies upon a variety of media. It excretes pectinase and oxidising enzymes, and induces disease upon apple, pear, plum, quince, orange, lemon, turnip and parsnip

Insect Pests of Lavender Dr H F Barnes, of Rothamsted Experimental Station, has recently published a discussion on "Lavender Pests" (*J. Roy Hort Soc*, March 1935) Few caterpillars were known to attack this fragrant crop, but the present article describes no less than thirteen species which have used it for food Most of the species are very general feeders, and the list includes such common moths as the buff and white ermines, the garden tiger, lesser yellow underwing and the cabbage moth Excellent half-tone plates illustrate both the caterpillars and the moths bred from them Each species is described in detail, and its host range is given The dot, bright line brown eye, small angle shades, gothic, mouse, bearded chestnut, silver *Y*, and willow beauty moths have all been described, in addition to those mentioned above

Cosmic Ray Bursts and their Variation with Altitude. The bursts of ionisation (Hoffmann *Stösse*) which are produced in a closed chamber, have been studied by C G. Montgomery and D. D. Montgomery (*Phys Rev.*, March 15) at stations the altitude of which lay

between sea-level and 4,300 metres. The bursts were observed with and without lead above the chamber. The rate of occurrence of bursts increases with height much faster than the total intensity of the cosmic rays. The frequency distribution of bursts of different size remains approximately constant. The authors interpret their results in terms of Swann's theory, according to which the number of non-ionising primary cosmic rays remains constant as they go through the atmosphere, producing bursts *en route*. The probability of burst production, however, decreases as the rays pass through the atmosphere. On this view the probability of burst production in lead must follow a different law from the burst production in air.

Glare from Motor-Car Headlights. The dangers of the dazzle produced by motor-car headlights at night have been well known to every motorist for many years, but no thoroughly satisfactory method of preventing it has yet been devised. In a report issued by the Department of Scientific and Industrial Research (Paper No. 16, "The Evaluation of Glare from Motor Car Headlights". London: H.M. Stationery Office, 1*s*. 6*d*. net) it is pointed out that many factors contribute to the problem of glare; it is therefore very difficult to make practical road trials to assess the merits of various devices. This report gives a scientific method of analysing the various contributing factors, a knowledge of which is essential before the relative merits can be adjudged of the various devices. The term 'glare' is used to denote the driver's power to detect objects ahead of him on the roadway. The principal factors involved in determining this power are the candle power in the direction of the observer's eye of the approaching light, the relative positions of the two cars and the object to be detected, their speed and the reflection factor of the road surface. The results obtained enable a quantitative study to be made of the conditions of visibility in the cases of a simple headlight using no anti-dazzle device, a dipped and swivelled headlight and a headlight giving a flat-topped beam. A factor of primary importance is the threshold difference in brightness between an object and its surroundings. Owing to the absorption or scattering of light by the atmosphere, the threshold value depends largely on the presence of mist or fog. Unfortunately, this threshold value varies with the previous exposure to light of the observer's eyes. The methods described in this report should enable the existing types of headlight beam to be compared quantitatively, and should aid in the discovery of the best type of beam for universal adoption.

Artificial Radioactivity Produced by Neutron Bombardment. E. Fermi and his co-workers have published (*Proc. Roy. Soc.*, A, April 10) an account of their further experiments on the production of artificial radioactivity by neutron bombardment, of which preliminary accounts have already appeared in Italian. The most interesting result is the enormous increase in the activation of many elements when a quantity of a hydrogen-containing substance such as water or paraffin wax is placed in the neighbourhood of the element and neutron source. Some elements do not show this increase of activation, but it is observed in every case where the product of irradiation is known to be isotopic with the original element. Fermi's explanation of this effect is the slowing down of the neutrons by impacts with hydrogen nuclei. The slow neutrons are very effectively captured by atomic nuclei, giving rise to new radioactive nuclei. A number of experiments have been performed to elucidate this effect. It is shown that the slow neutrons are strongly absorbed by some elements; the nuclear cross-section of cadmium, for example, reaches the relatively enormous value of 10^{-20} sq. cm. The capture of the slow neutrons is in some cases accompanied by a γ radiation. Chadwick and Goldhaber have shown (see NATURE of January 12, 1935) that the capture results in the case of boron and lithium in the emission of particles of short range. Fermi attempted to find an effect on the activation due to varying the temperature of the hydrogen containing block. Such an effect might be expected if the neutrons were slowed down to velocities comparable with thermal velocities. No temperature effect was found; but Fermi points out that this result is not quite conclusive about the final velocity of the neutrons [see also this issue of NATURE, pp. 903–5]. Experiments have been made on the scattering of the slow neutrons, and they show that once the velocity is reduced to values at which the high efficiency of capture appears, the scattering by hydrogen is also considerable, the mean free path being of the order of a few millimetres in water. A small increase in the activation is observed when other elements such as lead, silicon and carbon are used instead of water or paraffin, and the mechanism of production of slow neutrons seems in this case to be obscure. The paper contains also some theoretical considerations on the properties of slow neutrons, and a systematic account of the activation of a large number of the elements.

Oxidation of Carbon. A new method discovered in the Northern Coke Research Committee's Laboratory of evaluating metallurgical cokes was outlined in a paper before the Durham University Philosophical Society by Dr. H. L. Riley, the director, on May 10. It is well known that in reactivity to oxygen, charcoal stands at the head, and graphite (or diamond) at the foot of the series of fuels, with low temperature, gas, and metallurgical cokes between. Some precision has been given to such determinations by earlier work at the station leading to a quantity known as the 'critical air blast', which is the minimum current of air which will maintain the combustion of a standard coke sample. This value is of considerable value in the choice of cokes for the domestic fire. In experimenting with wet oxidation methods, it has now been found that determination of the carbon dioxide liberated on oxidation of a graded coke sample by means of a saturated solution of potassium dichromate in syrupy phosphoric acid is a valuable indication of the quality of coke for metallurgical purposes. The above order of reactivity is reversed, except that the position of wood charcoal is anomalous (sugar charcoal is unreactive), and also diamond. There appears to be correlation with the proportion of graphite present, retort carbon oxidising readily. It was suggested that the reactivity to oxygen depends on hydrocarbon impurities, whereas these are relatively stable to the wet method, while the latter attacks the long weak valencies (3·4 A.) between the layers of graphite in the crystal lattice. Further, the negative chromate ion must be supposed to attack the positive centres, which must be present since graphite is a conductor of electricity like a metal.

The Art of Primitive Peoples

AN exhibition of the art of primitive peoples, which will remain open until the end of July, is now on view at the Burlington Fine Arts Club, 17 Savile Row, London, W 1 It covers a sufficiently wide field to afford an opportunity for comparing and contrasting the ideals and achievement of the æsthetic sense among peoples of a widely differing cultural history and geographical environment, and of estimating how far, if at all, a common element is to be discerned in the development of artistic principles in varied conditions of race, technical skill and material employed as the medium of expression While technique varies considerably in the specimens shown in the present exhibition, it is striking at a first glance how little, relatively, the tools employed, whether of stone, shell or metal, affect the 'polish' of the finished product Hence, while it is true that this collection contains some of the finest known examples of so-called primitive art—it is indeed a possible criticism of the exhibition that it includes so little that is crude, but at the same time scientifically instructive—the general level of execution is higher than might reasonably be expected There are few specimens that fail to attain the highest possible degree of finish of which the artist's intention was susceptible The decorative designs, for example, applied in Polynesia to nearly every object of wood even in daily use, such as the paddle from Austral Islands (No 132) or the Maori tattooed head (No 261), though carved with stone or shell, are often so delicately executed as to have an apparent superficial texture of lacework

The peoples whose art is illustrated in the exhibition are widely distributed geographically Both in number and artistic achievement the exhibits from West Africa hold first place The remainder of the exhibits are drawn mainly from the South Seas, the most important sections being that of New Guinea and the art of the Maoris of New Zealand , but the Solomons, Easter Island, the Sandwich Islands, the Marquesas and other groups are also represented America has been expressly excluded, as an exhibition of American art was held by the Club a few years ago , but there are a few masks and other objects made by the Indians of the North West Coast and a collection of Eskimo ivory carvings One case contains a miscellaneous collection of objects from areas not represented elsewhere in the exhibition. Here some bone needle-holders from Borneo and New Guinea show an incised scroll pattern which, in the use of a south-eastern Asiatic foliate *motif* highly conventionalised, contrasts markedly with other exhibits

In an exhibition of this kind it is difficult to keep the anthropological and the artistic interests nicely balanced, and the rarity or ritual purpose of certain objects may tend to absorb attention to the neglect of artistic merits. Such, indeed, may be the fate of the whole of the collection of objects from the Sepik River, New Guinea, lent by the University Museum of Archæology and Ethnology, Cambridge, among which are the remarkable and unique ceremonial feather-covered boards, of which the longest is 4 ft 9 in long (No 245), and the orator's stool, which is beaten violently while the orator speaks, but is never sat on (No. 33).

An exhibition of 292 items, each of which anthropologically or artistically—and usually on both counts—is a treasure, precludes any attempt at detailed description A bare mention of a few of the more striking specimens must suffice The important exhibit of examples of West African art statuettes and carvings in wood and ivory and castings in bronze - includes a number of examples of the well-known Benin art. The general character of this group of exhibits will not be entirely unfamiliar to the public, thanks to the recent exhibition of African art Those, however, who know it only from the illustrations which appear in books on African art, can have little conception of the vitality and purpose, which override faults in proportion, according to European standards, when these examples are seen in the round Among the more striking examples here are the Benin flute-player (No 68) and the carved ivory mask from Benin (No 110) , but even more remarkable in its kind is the carved ivory sistrum with beaters, also from Benin There is also a wonderful expression of purpose, which is emphasised by the disproportionately short legs of the figures, in the wooden head-rest supported on two females with arms entwined, from the Congo (No 126) The list of examples deserving prolonged study might even be extended to the whole of this section, if other exhibits did not equally demand attention

Though less spectacular, the small collection of Eskimo ivory carvings is one of the most attractive and arresting features in the exhibition It consists of male and female figures, a mask, a number of toggles, arrow straighteners, amulets and bow-drills. All, but particularly the amulets and toggles in the form of seals, whales and other fauna, display a wonderful realism and appreciation of the niceties of animal forms The gems of this collection, however, are the ivory bows for fire drills (Nos 48-55), which are covered with figures of animals or with hunting and fishing scenes incised in a space which, at most, does not exceed three-quarters of an inch in breadth These pictures, minute as they are, are instinct with vitality, full of action, and almost photographic in their truth to life

The exhibits from the South Seas, and especially the section devoted to the Maori art of New Zealand, includes some choice specimens , some are already well known, while others, such as the War God from Hawaii collected by Capt Cook on his last voyage (No 189), are of historic interest The use of 'mother of pearl' as an inlay, especially in the human figure, is well illustrated in the Solomon Islands group, while of all the representations of the human form in this section, the emaciated figures from Easter Island, with their peculiar facial character, continue to arouse the most interest, and to prompt what is, unfortunately, in the circumstances, a not very profitable ethnological speculation, New Guinea, outside the Sepik River area already mentioned, is well represented in a number of specimens in which the ethnological interest is perhaps greater than the purely artistic. Among these are specimens from Dr. A. C. Haddon's collections from the Torres Straits

The list of objects to which reference should be made is far from exhausted , but enough has been said to indicate the importance of the collection as a whole as a demonstration of the artistic capacity of those backward peoples, to whom few outside the ranks of the student are habituated to conceding recognition in this field of activity.

Report of the Commissioners for the Exhibition of 1851*

AMONG the manifold recollections aroused by the Royal Jubilee, it is fitting that we should spare a moment for a backward glance to that May day of eighty-four years ago, when a vast concourse of people from all parts of the world were thrilled by the opening of the Great Exhibition of 1851, and, therewith, a tribute to the potent and beneficent spirit of its creator, the Prince Consort "A complete and beautiful triumph," wrote the Queen in her diary of the opening day, and it became evident in the course of the summer that the venture was to prove a financial triumph Some weeks before the closing day, the Prince excogitated a scheme for the disposal of the surplus, which amounted to £186,000. Its leading ideas, as set out in a memorandum written by him at Osborne on August 10, were the purchase of the Kensington Gore estate and its use for perpetuating the objects of the exhibition, so "that the different industrial pursuits of mankind, arts, and science should not again relapse into a state of comparative isolation from each other"

The publication of the Commissioners' ninth report is well timed The eighth was published in 1911, so that the present report covers almost exactly the period of the reign of H M King George, and it shows how during that period his grandfather's remarkable foresight has had an accumulative influence upon higher education and upon the progress of science and art It expresses the belief that "the Kensington Estate to-day, with its Museums, Libraries, Teaching Institutions and Scientific Societies, fulfils in its range and completeness the aspirations of the Prince"

The policy of the Commissioners since 1911 has been guided by the decision then formed to spend no more money on buildings but to concentrate effort on subsidising youthful talent It was in pursuance of this policy that they established the industrial bursaries, on which they now spend £3,750 a year, or more than a seventh of their income They hoped thereby to bring the universities and their affiliated technical colleges into closer relation with scientific industry through introducing into industrial firms a larger proportion of men with a scientific training and outlook The bursary is intended to make the holder independent of financial assistance from his parents during the period of his training and to remove any restriction upon his choice of occupation or place of abode, with suitable safeguards against the unfair exploitation of the scheme in the immediate pecuniary interests of the employer. In this way more than three hundred well-equipped young students have been helped into industry, and a number of the chief scientific and executive officers in the most important industrial concerns in Great Britain began their careers as bursars of the Royal Commission Already fully 25 per cent of those employed in industry and the public services have been appointed to positions of considerable responsibility, while 13 per cent hold managerial or equivalent rank. Simultaneously "there has manifested itself a clearer appreciation of the benefits to be derived from a more liberal treatment of those in whose ranks are to be found many of our future captains of industry".

Another development since 1911 has been the foundation of a postgraduate scholarship in naval architecture, the need for which had been pointed out by H.M King George when he was president of the Commissioners Practically all the scholars appointed are in permanent positions on the design, research and administrative staffs of industrial firms and Government institutions

Science research scholarships were first instituted by the Commissioners in 1891 under a system which continued in force with excellent results for thirty years, in the course of which they were supplemented by other schemes modelled upon them by various bodies interested in the promotion of science In 1921 it was recognised that the provision made by the Department of Scientific and Industrial Research for scholarships of the same type justified the Commissioners in leaving this field and launching a project whereby a smaller number of awards of much higher value (maximum £450 a year for two or three years) should be made to enable a few experienced research workers in the universities of Great Britain to continue their investigations untrammelled by routine tasks. These are known as senior studentships and they cost £5,250 a year At the same time, the value of the awards to students from the Dominions was increased to £280 and these, the Overseas Scholarships, absorb £6,250 No important university in the Dominions is, the Commissioners observe, without its quota of professors and lecturers who owe their early training in research to these awards, and any additional funds placed at the Commissioners' disposal might advantageously be applied to extending their scope to include the more recently developed countries of the Empire, and in particular India

A census taken some years ago showed that the 560 scholars appointed between 1891 and 1929 had already provided 16 vice-chancellors, principals or deputy principals, 144 professors and many more readers and lecturers on the staffs of universities and colleges, and more than two hundred held positions of the first rank in the public services and scientific industries of the Empire No fewer than forty have already been elected to fellowship of the Royal Society

H M Government has been so impressed by the high value of the Commissioners' educational schemes that it has agreed to release them from further liability, under an offer made by them before the general trend of their policy was changed in the direction already indicated, to contribute £100,000 (of which £35,000 has already been paid) towards the cost of new buildings for the Science Museum, South Kensington

* Ninth Report of The Commissioners for the Exhibition of 1851 Pp. 44. (London: Spottiswoode, Ballantyne and Co, Ltd, 1935)

East Anglian Herring*

THE Buckland Lectures for 1933 were given by Dr. W C Hodgson and forecast the publication of researches of great scientific interest relating to the East Anglian herring. They are the result of the team work of the scientific staff of the Ministry of Agriculture and Fisheries, and are quite sufficient in themselves to justify the foresight of the Ministry in the establishment of its laboratory at Lowestoft, in which such team work could be developed.

The working out of year groups in the herring catch, as shown in the rings of the scales, is carried much further and furnishes exact percentages,

* The Natural History of the Herring of the Southern North Sea being the Buckland Lectures for 1933. By Dr William C Hodgson Pp 120 (London Edward Arnold and Co., 1934) 3s 6d. net.

founded at last on sufficiently large samples The group of each year, estimated on its year of birth, is charted, and the fish are measured, thus giving a complete record of the changes in size of the herrings from year to year There was a rich brood born in 1915, and this richness continued every third year, until there were lapses in 1930 and 1933 A good crop of certain small crustaceans (especially *Calanus*) as food, concentrated in a small area, was found to produce a good fishery, the drift net method of fishing requiring a concentration of fish A plankton indicator, showing the presence of these copepods, in the hands of one experienced master mariner, became a catch indicator, the presence of *Calanus* meaning a trebling of the catch On the other hand, the presence of a flagellate (*Phæocystis*) or of certain diatoms (*Rhizosolenia*, *Biddulphia*, etc) drove away the herrings from the ground, and even altered their line of migration. Thus in 1933 the East Coast drifters had to make long voyages to the north east to find the herrings, and the cause proved to be an enormous belt of phytoplankton across the southern bight of the North Sea, *Rhizosolenia* to the west and *Biddulphia* to the east, both equally distributed from the surface to the bottom of these shallow waters

Other interesting observations relate to the correlation of the heaviest commercial catches with the periods of full moon, thus obviously not tidal phenomena Between the peaks of the curves are very definite troughs, the difference in the average landings varying from 60 to about 15 crans (see NATURE, 135, 157, Jan 12, 1935)

There is much more, the indication being that the North Sea will be farmed internationally, if human population increases For this the British team is obviously supplying data, while contemporaneously producing scientific results of a class of which the lone research student can never dream At the same time the lack of a market for the herring, our most valuable and cheapest food fish, discourages further research. Here is another team work job, this time for the Food Production Division of the Department of Scientific and Industrial Research, so that the herring may be proffered to the public in a good variety of palatable forms throughout the whole of the calendar year.

University and Educational Intelligence

CAMBRIDGE —The Managers of the Balfour Fund have made a grant of £50 to G J. Kerrich, of Christ's College, for researches on the palæarctic fauna of the north of Finland

The General Board recommends that an assistant directorship of research in physics be established from October 1 in view of the reorganisation of the teaching staff in the Department of Physics at the end of the present academical year.

Graces will be submitted to the Senate recommending the conferment of the degree of M.A. (*honoris causa*) on Mr. E A. B Barnard and Dr. W. M Palmer Mr. Barnard is secretary of the Cambridge Antiquarian Society. He has rendered great service to the Corporation of Cambridge by calendaring in collaboration with Dr. Palmer its collection of medieval manuscripts.

Dr. A. C. Haddon's eightieth birthday was marked by the presentation by his friends of a cabinet containing his collection of ethnographical photographs. Dr. Haddon is handing over the collection to the Board of Archæology and Ethnology to make it available for instruction and research.

GLASGOW —Prof Thomas Alty, research professor of physics in the University of Saskatchewan, has been appointed Cargill professor of applied physics. The Cargill chair is the junior chair in the Department of Physics, or Natural Philosophy as it is still termed in the Scottish Universities, and is concerned with the instruction of students proceeding to the various degrees involving applied science such as engineering, applied chemistry, pharmacy, medicine and agriculture Prof Alty received his early training in the University of Liverpool, where he had a distinguished career, and thereafter worked at Cambridge under Sir J. J Thomson While at the Cavendish Laboratory he carried through the admirable research on the cataphoresis of gas bubbles in water which gained him his degree of Ph D His subsequent published work deals with such subjects as the surface structure of liquids, the interchange of molecules and energy between a liquid and its vapour, the electric properties of surfaces and the theory of surface diffusion, while as regards industrial applications of physics he has interested himself especially in the application of electrical methods to the location of underground accumulations of oil, water, metals, rocksalt, etc Prof. Alty takes with him to Glasgow a high reputation as a teacher both in the laboratory and the lecture room

The University Court has now, after long but unavoidable delay, been able to bring into being the Tennent chair of ophthalmology to which it was decided in 1916 to devote a bequest of £25,000 by the late Dr Gavin P Tennent As first holder of the chair, Dr A J Ballantyne has been appointed, after a distinguished tenure of the University lectureship on ophthalmology since 1920

LIVERPOOL —Associate Professor James Rice has been appointed to a readership in theoretical physics Mr Rice was one of the first men in England to grasp the significance of Einstein's principle of relativity and theory of gravitation, and his academic work on this subject was one of the earliest expositions in English He has interested himself in the theoretical aspects of atomic physics and the quantum hypothesis, while his book "Statistical Mechanics" is a standard work dealing with the fundamental theoretical methods by means of which the complex phenomena of the atomic world are rendered amenable to mathematical treatment.

Dr. Norman Feather has been appointed to a lectureship and Leverhulme Foundation fellowship in the Department of Physics as from October next. Dr Feather was a scholar of Trinity College, Cambridge and is at present attached to the Cavendish Laboratory, Cambridge. He is already well-known for investigations on neutrons and related topics in atomic physics.

At a Congregation on May 24 the honorary degree of LL.D was conferred upon the following, among others: Prof. Arthur Harden, formerly director of biochemistry at the Lister Institute, London; Mr C Thurstan Holland, formerly lecturer in radiology, University of Liverpool, president of the first International Congress of Radiology, Dr N. V Sidgwick, president of the Chemical Society, and Prof Alan J. B. Wace, professor of classical archæology, University of Cambridge.

LONDON.—Prof. J. A. S. Ritson, professor of mining in the University of Leeds, has been appointed to the University chair of mining tenable at the Imperial College (Royal School of Mines) from January 1, 1936.

OXFORD.—Prof. Julian Huxley has been granted the degree of D.Sc.

Mr. A. J. Ayer has been elected to a research studentship (that is, fellowship) at Christ Church. In addition to problems in formal logic, Mr. Ayer is working on the philosophy of science.

Science News a Century Ago

An Inventor of the Screw Propeller

On June 1, 1835, Thomas Charles Auguste Dallery, one of the inventors of the screw propeller, died at Jouy-en-Josas, near Versailles. Born at Amiens on September 4, 1754, he showed a great aptitude for mechanics, and succeeded to his father's business of an organ builder. Just before the French Revolution, he was commissioned to build an organ worth 400,000 francs for the cathedral of his native city, but the order was cancelled. He afterwards turned his attention to steam navigation, and in 1803 constructed at his own expense a steam-boat driven by a screw or *escargot* as he called it. The vessel was launched on the Seine at Bercy; but, like the attempts of so many other pioneers, Dallery's efforts proved a failure. His patent included several innovations besides the screw, among them being a boiler with vertical tubes. Nine years after his death a commission of the Paris Academy of Sciences, composed of Arago, Dupin, Morin and Poncelet, examined the claims of the Dallery family in regard to his inventions, and reported favourably on them.

South American Deserts

In his "Journal" of his journey northward from Coquimbo to Copiapó, where Capt. FitzRoy had offered to pick him up, Darwin records on June 3, 1835: "Yerba Buena to Carizal. During the first part of the day we crossed a mountainous rocky desert, and afterwards a long deep sandy plain, strewn with broken sea shells. There was very little water, and that little saline; the whole country, from the coast to the Cordillera, is an uninhabited desert. I saw traces only of one living animal in abundance, namely, the shells of a *Bulimus*, which were collected together in extraordinary numbers on the driest spots. In the spring one humble little plant sends out a few leaves, and on these the snails feed. As they are seen only very early in the morning, when the ground is slightly damp with dew, the Guasos believe that they are bred from it. I have observed in other places that extremely dry and sterile districts, where the soil is calcareous, are extraordinarily favourable to land shells".

Earthquakes in Sussex

At a meeting of the Royal Society on June 4, 1835, the secretary, Dr. P. M. Roget, read a "Report of a Committee for collecting Information respecting the Occurrence of, and the more remarkable Phenomena connected with, the Earthquakes lately felt in the Neighbourhood of Chichester", which had been sent to him by J. P. Gruggen. "This paper," said the *Philosophical Magazine*, "contains an authentic report of several shocks of earthquake which, during the last two years, have been felt at Chichester and the surrounding country; drawn up from accounts given by various correspondents, in answer to printed queries extensively circulated. The first shock occurred on the 18th of September and the second on the 13th of November 1833. Another and more severe shock was felt on the 23rd of January 1834, and in the latter end of the same year two slighter shocks were experienced, namely, one on the 27th of August, and the next on the 21st of September; the last, which was less than any of the former, took place on the 12th of January 1835."

The Process of Malting

Among the original contributions to the *Records of General Science* of June 1835 was an article by Prof. Thomas Thomson and Dr. Andrew Steel on the "Chemical Analysis of Gadolinite together with an Examination of some of the Salts of Yttria and Cerium", and another "On Malt", by the editor, Dr. R. D. Thomson. In the course of his article, Dr. Thomson said: "The process of malting consists essentially 1st in producing a change in the constituents of grain by inducing germination; and 2nd in stopping the vegetation when it has been carried to a certain extent by exposure to heat". The subject was one which was exciting some interest at the time and Dr. Thomson added: "A knowledge of the peculiarities of this interesting process is important in a double point of view, because it affords a remarkably beautiful specimen of the chemistry of nature, and because its product forms a staple commodity of British manufacture, no less than forty millions of bushels of malt being annually consumed in the United Kingdom, which at 60*s.* per quarter, exceeds in value the large sum of £24,000,000 and contributes to the Government at 2*s.* 7*d.* per bushel more than £5,000,000 per annum".

Encouragement of Discovery and Invention*

A FEW years ago the International Committee of Intellectual Co-operation, "considering that intellectual property was not then sufficiently protected and that scientific property particularly was at that time not protected at all, entrusted a subcommittee consisting of MM Destree, Millikan, Ruffini and de Torres Quevedo with the duty of examining the means by which this protection might be assured" Many schemes for affording protection were examined, among them being one for the establishment of an international bureau , a second, for the creation of a fund contributed to by manufacturers , a third, for the donation of Government funds to the discoverer , and a fourth, for the extension of the patent system to include scientific discoveries No definite scheme for protecting scientific discoveries was, however, adopted, and in consequence the problem of affording protection was afterwards reconsidered by a committee of the American Association for the Advancement of Science After careful consideration of the problem the committee expressed the opinion, first, that the results of research (other than medical research) that have any possible commercial importance or industrial application should be patented , and secondly, that apart from this variation of the means at present adopted for protecting scientific discoveries, no practicable and desirable alternative had been proposed The opinion that the results of research should be patented is apparently being widely followed in Great Britain, if it is permissible to judge from the fifty-second Report of the Comptroller-General of Patents, which has just been published

In a statement on the trend of invention during the year 1934, the Report states, for example, that considerable advance in the field of patented chemical invention has been shown in sensitising dyes used for photographic purposes, due to a closer understanding of the relationship between absorption spectra and chemical composition of the dyes, whereby sensitising action over increasingly diverse parts of the spectrum is obtained Further, although the discovery of the hydrogen isotope, deuterium or diplogen, is at present mainly of academic interest, applications are being received of means for obtaining 'heavy water' and for the production of organic compounds containing 'heavy hydrogen'. Attention is being

* Patents, Designs and Trade Marks Fifty-second Report of the Comptroller-General of Patents, Designs and Trade Marks, with Appendices for the Year 1934. Pp 24 (London H M. Stationery Office, 1935) 4d net

increasingly directed to sexual and other hormones, and a better knowledge of their chemical constitution has brought appreciably nearer the synthesis of some of those bodies and the manufacture of compounds or derivatives which exhibit to some extent the physiological properties of the hormones

The Report states also that in the electrical arts there have been noteworthy developments in connexion with heavy-current arc rectifiers of the non-mercury type, arc-less switching in high-power switch gear, high-frequency induction coils with compressed powder cores of low permeability, and permeability tuning units in which the magnetic properties of the cores differ according to the positions of the coil and core There has been a continued increase in inventions in connexion with electrical discharges through high vacua or gaseous media as, for example, in X-ray tubes of hitherto unknown proportions working on voltages of the order of half a million In electrical impedance networks for filtering and other purposes, the mathematical technique is being developed in such a manner as to enable problems of increasing generality to be solved by systematic methods The prospect of commercial broadcast television has made cathode ray tubes the focus of much invention, and is leading to the development of amplifiers suitable for handling a wide range of frequencies and to the use of special oscillators for producing deflecting potentials of saw-tooth wave form It will be agreed from these examples in the Report that some scientific men in Great Britain at least appear to be following the advice of the American Association committee to patent those results of research that have any possible commercial importance or industrial application.

The American Association committee also expressed the opinion that, apart from patenting the results of research, no practicable alternative to the very inefficient means at present adopted for protecting scientific discoveries has been proposed As this opinion has been generally accepted, it appears probable that the present inefficient means will perforce continue, and therefore it is advisable that consideration should from time to time be given to the question whether the existing machinery of the rewards for discoveries and inventions can be made to work more efficiently than it has hitherto done. An important part of this machinery is the publication in proper form of discoveries and inventions, because the encouragement of work in those fields, whether it be by honours, professional appointments, patents or otherwise, is very largely dependent ultimately on public acknowledgment of the results The Report brings to mind the different methods of considering and publishing those scientific discoveries that are not patented, and inventions that are, and leads to two suggestions for improving these methods

The first suggestion relates to the form in which scientific papers and specifications of inventions are published The specifications of all patented inventions have undergone examination in the Patent Office by examiners expert in the various subjects and have been accepted by the Comptroller and published in a form that ends with "a clear and succinct statement of claim" of what constitutes the invention Further, the inventions have been classified according to the subject-matter and the classification published, although the Report states that

"The rise of new arts and the rapid and unpredictable developments in others during the past few years have raised serious and urgent problems in the classification of the subject-matter of specifications Some progress has been made in the solution of these problems, and it is hoped that a revised classification of such matters as the automatic control of machines and apparatus, and the manufacture of synthetic resins and cellulose and its derivatives, will soon be ready for publication."

It might be difficult for our scientific societies to deal in a similar manner with the various papers that they publish, but it would probably simplify their procedure, and it would certainly facilitate classification and future reference, if they were to insist that each paper should contain a clear and succinct statement of what the author claims as his discovery in view of the state of scientific knowledge at the date of publication. The mass of published scientific papers that are insufficiently classified, and contain only vague description, is increasing at such a rate that it seems likely to constitute a mountainous obstacle in the path of future generations of scientific research workers.

The second suggestion relates to the conditions under which scientific papers and specifications of inventions are accepted Scientific societies appear to be more favourably placed for considering papers submitted to them than is the Comptroller-General of Patents for dealing with specifications of inventions, in that societies can refuse any paper on the ground of subject-matter or rather lack

of it, while the Comptroller is not, in general, empowered to refuse to accept a specification on the ground of lack of subject-matter of the invention. One result of this limitation of the power of the Comptroller is that there have come into existence many 'paper' patents that are clearly invalid and are a nuisance to the public It would certainly be no harm to the really meritorious inventor, and would probably be greatly in the public interest, if the Comptroller were empowered to refuse to accept a specification on the ground of lack of subject-matter

Reviews

Relativity, Thermodynamics and Cosmology

Relativity, Thermodynamics and Cosmology By Prof Richard C Tolman (International Series of Monographs on Physics) Pp xv+502 (Oxford Clarendon Press , London Oxford University Press, 1934) 30*s* net

THE general theory of relativity has now been before the scientific world for some twenty years, and the special theory considerably longer Fifteen or sixteen years ago, the theory may be said to have definitely superseded Newtonian mechanics in the treatment of macroscopic phenomena, and the whole of physical science, with the partial exception of atomic problems, acquired a new foundation The superstructure, of course, was in the main unaltered, for the new mechanics faded into the old for all but the most fundamental matters, but the basic laws and equations of physics demanded re-statement, and in a few particulars their requirements were at variance with those of classical theory. In these circumstances there was clearly a need for a general statement of the new position, and for more than a decade this need has been satisfied for English-speaking readers by one book—Eddington's well-known "Mathematical Theory of Relativity" There is now a second

Comparison is inevitable, and fortunately can be made without invidiousness In the first place, since Eddington's latest edition differs only slightly from its original, Tolman's book presents the achievements of twelve years' work of which "The Mathematical Theory of Relativity" takes no account. Eddington's treatment of cosmology, for example, is confined to a description, without details, of the now outgrown Einstein and de Sitter universes, while Tolman devotes 150 pages to a comprehensive discussion of all the models of the universe (except that of Milne, which stands outside the applications of general relativity) that have been proposed Much of this section represents his own original work. Again, thermodynamics—which, as an important branch of mechanics, must obviously be re-expressed in relativity terms—is given full treatment by Tolman (whose book, in fact, must now be regarded as the only up-to-date treatment of thermodynamics in existence) but is untouched by Eddington This work is entirely Tolman's own, except for the contributions of collaborators in some of the applications On the other hand, in order to cover so wide a field as Tolman has chosen, some sacrifice of detail has been necessary, and for the mathematical proof of many of the fundamental relations the reader is referred to Eddington Useful appendixes summarise notation, formulæ and constants which frequently occur

The most important difference between the books, however, arises from the difference in outlook of the writers Eddington presents relativity as the spectacle seen from a certain extra-physical point of view Tolman, adhering more closely to the historical development, may be said to describe the journey towards the present position from which Eddington looks back to survey the landscape his culmination is Eddington's origin Thus, while to Eddington special relativity is a particular case of the general theory in which the $g_{\mu\nu}$ happen to be constant, Tolman sees it as a necessary step to general relativity and gives it independent and equal treatment Eddington is preoccupied with the idea, Tolman with the application , Eddington with the philosophical aspect of physics, Tolman with the physical aspect of philosophy

It is a necessary consequence that the books will appeal to minds of different types Those who find themselves responding to and enlightened by Eddington's treatment will tend to classify Tolman's work as a textbook valuable for occasional reference and for enabling one to pass examinations Those, however—and they are many—to whom Eddington is mystical and even unintelligible, will probably find in Tolman precisely what they have been looking for—a clear, accurate, physical account of an important branch of pure and applied science Blessed are they who can appreciate the qualities of both, for theirs is the kingdom of relativity

It is impossible in a brief review to indicate more than the outstanding features of such a book as this. First and foremost, the admirable 'sanity' of the treatment calls for comment. By this we

mean that consistently and evidently easily maintained attitude of stability between the Charybdis of unbridled speculation and the Scylla of blinkered restriction to the palpable and tangible, which in these days is so difficult to preserve and so rarely found. The representation of a physical system as a Riemannian manifold is clearly described and its advantages emphasised, but it is never regarded as more (or less) than a very useful device, and in the discussion of both special and general relativity the geometrical treatment is given as an independent account of the phenomena running parallel to the mechanical or analytical account In the cosmological section, again, it is never "the universe" that is discussed, but "models of the universe", and the relations between such models and astronomical observations are clearly pointed out One of the most valuable sections of the book, in fact, is that which treats of the wide gap separating the coefficients, $g_{\mu\nu}$, of relativity formulæ from the measurements actually made in the observatory The connexion, for example, of what we call the "law of nebular recession" with these coefficients on one hand, and with the blackening of a photographic plate on the other, though one of the most difficult and important problems of modern science, is usually slurred over as though it did not exist Here alone, so far as we know, is an attempt made to deal with it, and though the final treatment probably yet remains to be given, one rises from this book with a greatly clarified view of the nature of the problem

The writing is clear and unadorned, though never repellent by its austerity If occasionally we would like a little more elaboration, we are more often thankful that the ideas are expressed so concisely and not obscured by excessive elucidation No attempt is made to describe the various unified theories that have been proposed with the object of including gravitational and electro-magnetic phenomena in a single scheme of mathematical expression A wholly satisfactory theory of this type has not yet appeared, and it is probably wise to leave the whole matter outside a book which, however it may have to be modified as knowledge grows, does at least represent a consensus of opinion among those interested in these matters at the present time

From one point of view, the most important section is that dealing with thermodynamics This, as has been said, is Tolman's own peculiar field, and although the re-expression of thermodynamics in relativistic terms has at present no practical application outside cosmology, its effect there is sufficiently revolutionary to claim for it much greater attention than it has yet received. For some reason a physical system gains enormously in popular prestige if it is called "the universe", and the prospect of the final running-down of the universe has caused sufficient heart-burning to make a statement of the actual probabilities very desirable According to relativistic thermodynamics, equilibrium in a gravitational field requires not uniform temperature but a temperature gradient to prevent the flow of heat from regions of higher to those of lower gravitational potential Reversible processes can take place at a finite rate, and irreversible processes are possible without the attainment of a maximum entropy Consequently, to use Tolman's very cautious words, "at the very least, it would seem wisest if we no longer dogmatically assert that the principles of thermodynamics necessarily require a universe which was created at a finite time in the past and which is fated for stagnation and death in the future" Disagreement with these results would be intelligible, though they have never been challenged and are accepted by many relativists, including Einstein himself What is incomprehensible is the neglect, excusably mistakeable for a conspiracy of silence, which has been their lot while the doctrine of the inevitable heat-death of the universe has been preached as an inevitable requirement of modern science

Mention should be made in conclusion of the excellent printing There are a few misprints, but we have noticed none that seriously affects the arguments HERBERT DINGLE

Primitive Vital Statistics

Primitive Society and its Vital Statistics By Prof Ludwik Krzywicki. Pp xiii+589. (London Macmillan and Co , Ltd , 1934) 20s net

IN order to form a picture of the state of society at any time or place, some knowledge of the density and the distribution of population is very much to be desired, and may even be said to be almost indispensable In its absence the picture can have no clear outline. If, in addition, something can be said about marital conditions and about vital statistics (and in particular about the expectation of life), such details are very illuminating It is a matter for comment that historians and anthropologists seem so often to be unaware of the importance of the matter It is true that it is only for recent times and for certain peoples that the information is at all complete ; but there is much information of some interest, and yet there is a failure to see its importance and to use it If anyone doubts this, let him examine some history textbooks, and notice how seldom the heading 'population' occurs in the index For compilers of anthropological textbooks there is the

excuse that the information has not been summarised hitherto, and therefore, such as it is, is not easily available But this does not excuse the anthropologists, who have seldom given the matter much attention when in the field, and have never attempted to gather together the facts that are known

It has been left to the professor of social history at the University of Warsaw to perform the latter task. Dr. Krzywicki has worked on the problem for more than thirty years, and now presents us with the results of his researches The efforts of one man, however long pursued, cannot fully cover so enormous a field, but it may be said that, whereas there was formerly no organised knowledge of the population and vital statistics of primitive society, we now have a wealth of data subjected to critical analysis Dr Krzywicki is very fully aware of the defective nature of the material available With the best will in the world it is very difficult for observers in the field to obtain correct statistical data in any quantity about primitive races In fact, as the author points out, observers have seldom been much interested in this side of native life, and in consequence the existing numerical data "have really just got by chance into the pages of books of first-hand information"

The first matter to which the author gives attention is the size of the tribe and the density of population Here, as in regard to the other problems examined, the most extensive data come from Australia and North America He finds that out of some 120 Australian tribes, 70 number less than 500 persons, the average for all the tribes being less than 550 In North America the average size is greater, but out of some 500 tribes more than 300 number less than 1,000 persons. In the rest of America the position is similar. The strict limitation thus placed upon social intercourse is certainly a fact of the first importance in the attempt to understand primitive society and the stagnation which it characteristically exhibits

The author next addresses himself to the dying-out of primitive races after contact with Europeans His explanation is in line with that of other workers on the subject. The death-rate rises owing to the introduction of new diseases, the native scheme of life is destroyed. In consequence, there is little or no object in attempting to rear children who are likely to die, and for whom, if they survive, there is no obvious place. Therefore abortion and infanticide become more prevalent just when they are less needed

The largest part of Dr Krzywicki's work, however, is concerned with the vital statistics of primitive races before contact with Europeans had produced marked results. We are given a great mass of material, it is unlikely that any important additions to it will ever be made, because the search of the literature has been so thorough and the opportunities of getting new information are now so restricted The evidence points to a low fertility and a high infant mortality everywhere among primitive races It is unusual for a woman to bear as many as five children, the common number seems to have been between three and four Only about fifty per cent reach maturity Though Dr Krzywicki finds that infanticide was in some places very prevalent, he does not regard it as a very important factor, for two reasons The children killed were sometimes the weaker, more often they were from a family where there were already young children, therefore in any case the chance of survival was remote Though for the most part the author is concerned with collecting and analysing the facts, he also enters into some interesting discussions as to their implication, as for example, of the importance of the small size of the tribe

A M CARR-SAUNDERS

Life-Histories of Farm Weeds

Prof Dr E Korsmo's Weed Plates Series 1 Plates 1–30, comprising 42 Species of Weeds on Cultivated Soil 84 cm × 64 cm With Descriptive Booklet Pp 78 (Oslo Norsk Hydroelektrisk Kvaelstofaktieselskab Leipzig Koehler und Volckmar A-G und Co, 1934) Paper, 22 gold marks, Leather paper, cloth edges and eyelets, 38 gold marks

PROF KORSMO has conceived and produced the most accurate and detailed exposition that has ever been attempted of many common weeds in all stages of development. With the aid of generous financial support from Norwegian producers of synthetic nitrogen, three series of thirty plates each have been prepared for use as wall diagrams, specifically for teaching purposes The drawings have been made from living plants in natural colours, under Korsmo's personal direction and control, and their detailed accuracy is remarkable. The plates are accompanied by a separate text giving the common names of each weed in a dozen languages, and a general description of its characteristics and habits, together with explanations of the plate figures This text is being published in various languages, as most of the weeds are cosmopolitan in distribution

The illustrations cover a wide field, the aim being to show all the features characteristic of each weed during its life-history To this end, the morphological sketches are frequently supplemented by anatomical drawings, as, for example,

in *Chenopodium album*, where a leaf section shows the unusual type of pubescence in this species In *Taraxacum officinale* the regeneration from mutilated roots under various environmental conditions is demonstrated, together with sections showing the origin of secondary shoots It is impossible to indicate the wide range of developmental stages covered in these plates, but it is safe to say that all teachers of agriculture and students will find the plates a mine of information, and that experts are the richer by a valuable work of reference Prof. Korsmo is to be congratulated on the outstanding merit and value of this work and, not least, upon the ability and sympathy of the artists responsible for the drawings

Short Notices

The Endless Quest Three Thousand Years of Science By F W Westaway Pp xx+1080+51 plates (London, Glasgow and Bombay Blackie and Son, Ltd, 1934) 21s. net

IT is very difficult to review such a book as this—or perhaps we should say "this book", for there can scarcely be another such Judged by the aim which the title suggests it is, of course, a failure to deal adequately with 3,000 years of science in a single volume is a sheer impossibility The impossibility is, in fact, so obvious that such a judgment would clearly be absurd We can only take the book as an isolated phenomenon and record its effect on a mind freed from preoccupation with ideas of what it should be When this attitude is adopted, the result is wholly pleasurable The author talks to us out of a vast store of knowledge in a manner which, subject to a broad classification on a chronological and subject basis, is delightfully informal Biographical notes, descriptions of scientific institutions, quotations, expositions, criticisms, reflections mix with one another in the most casual way, and it is hard to imagine a more satisfying book into which to dip at those not infrequently occurring intervals which are too brief for systematic work and too long to be wasted Photographs and diagrams are numerous and excellent; there are questions for the problem-minded and bibliographies for those who wish to pursue the subjects raised; and there is a good index.

Of the two possible viewpoints—those of the present time and of the timeless observer—Mr Westaway has chosen the former. hence recent work assumes a prominence even greater than that to be expected from its great bulk From this cause arises what is perhaps the chief defect of the book; it is difficult on any grounds to justify the inclusion, in an account of 3,000 years of science, of the remarks of individual speakers at a Royal Society discussion on heavy hydrogen, for example But away with criticism · the book is a pleasure to read, and we are grateful to Mr Westaway for it.

Annual Reports on the Progress of Chemistry for 1934. Vol. 31. Pp 442. (London Chemical Society, 1935.) 10s. 6d

MUCH fundamental work is summarised in the Chemical Society's Annual Reports for 1934. Mr. R P. Bell gives an account of the heavy isotope of hydrogen. 'Heavy water', or deuterium oxide, is in fact now an article of commerce, being separated by an electrolytic method Dr L. A Woodward's section on the Raman effect gives a connected account of some of its applications, Dr N V Sidgwick discusses the theory of resonance and the co-ordination of hydrogen, and presents a short statement on heats of formation in homologous series, Mr E J Bowen contributes a review of work in chemical kinetics; Mr. Bell is responsible for sections dealing with electrolytes, kinetic salt effects, and acids and bases, whilst Dr H. W Thompson refers to the emission of electrons in chemical change, to certain spectroscopic considerations, to nuclear moments, to the structure of liquids, to optical activity, to valency and the structure of molecules, to supersonic waves, and to optical phenomena and energy transfers Prof R Whytlaw-Gray gives an account of atomic weight work, Dr W. Wardlaw of metallic carbonyl and nitrosyl compounds, of molecular structures, and of some of the rarer metals; Dr E S Hedges discusses the corrosion of metals The report on aliphatic organic chemistry is presented by Dr H D K Drew, Dr R S Morrell, Dr E L. Hirst and Dr S Peat, Dr G A R Kon and Dr T G Pearson are responsible for that on the homocyclic division, and Dr. E. E Turner for that on the heterocyclic division Analytical chemistry is in the charge of Mr. B A Ellis, Dr. J J Fox, Dr S. Glasstone and Mrs J. W Matthews. Dr C. P. Stewart and Mr A G Pollard present an account of advances in biochemistry, whilst Dr N. Feather discusses radioactivity and subatomic phenomena These reports are universally valued by chemists and others who wish to keep abreast of modern developments in the subject

A A. E

Chemical Engineering Plant Design. By Prof Frank C Vilbrandt. (Chemical Engineering Series.) Pp. x+341. (New York and London: McGraw-Hill Book Co., Inc, 1934.) 24s. net

ANYONE who purchases this book from its title and expects to acquire information on the design of various machines and plant used in chemical works will be disappointed, since the various chapters are devoted to such subjects as location, foundations, drainage, buildings, pumps, piping, and flow diagrams, power and power transmission, and preconstruction cost accounting. The problems considered, therefore, are those associated with the layout and construction

of a chemical works and not the design of the individual machines installed therein, although in one chapter entitled "Selection of Process Equipment" brief descriptions are given of the types of machines suitable for specific operations in chemical works

Throughout the book there are copies of questionnaires issued by various firms to enable them to assess the purchaser's requirements before submitting a quotation. There is also a large number of tables giving data upon a wide variety of subjects which would be valuable to anyone planning or constructing a chemical works As the theory underlying any design is not fully discussed, the utility of the book, which might well be entitled "Problems in Planning a Chemical Works", depends upon the data and hints accumulated from practical sources

The English in places is somewhat involved and prevents the reader easily acquiring the information which the author wishes to impart

Introduction to Early Roman Law Comparative Sociological Studies By C W Westrup *The Patriarchal Joint Family* 2 *Joint Family and Family Property* Pp iii+192 (Copenhagen Levin and Munksgaard, London Oxford University Press, 1934) 12s 6d net

In this volume—a memorial volume to Sir Henry S Maine—the author reviews two aspects of the family as an institution in the life of early Rome in so far as it is reflected in early law In type it conforms to the pattern of the Indo European joint family It is compared here with the family as it is found in the records of, or in survivals among, the Indo-European peoples, Teutons, Celts, Slavs and Indians

The controlling factor in both family organisation and inheritance of property was first the necessity for ensuring the continuance of the family cult and secondly the desire to preserve property as a group possession. The latter in the mind of the practical Roman was the more important binding force in securing the perpetuation of the family tie, centring in the inheritance by the eldest son as the controlling power in the group, but without the right of absolute possession or disposal The author here examines in detail the modifications of the type which were introduced in Roman practice and traces the course of development in the idea of the family and family property under the influence of various factors, of which in the main the growth of the concepts of the individual family and individual property were the most decisive

Elementary Qualitative Analysis By Dr F. M Brewer Pp viii+228 (Oxford. Clarendon Press; London: Oxford University Press, 1933.) 6s net.

There is a gratifying tendency for modern general text-books on analysis to become something more than collections of tables and recipes by the extension of their scope to include other matter. thus, a text on the quantitative side will deal with the underlying physico-chemical considerations. In the present handy volume, which for the sake of brevity confines itself to the familiar arbitrary common radicles, an attempt is made to emphasise the connexion between the analytical groups and the groups of the Periodic Table, thus combining the general behaviour of an element with its analytical reactions As an example, it is pointed out that, with one exception, those metals which are precipitated by hydrogen sulphide from acid solution occur in Nature predominantly as sulphides; this relationship, which can be extended to other insoluble compounds utilised in qualitative work, has a perfectly simple explanation, and yet is almost universally overlooked

Of the general descriptive matter, little need be said since almost of necessity it must follow the familiar lines; nevertheless, in view of the dual purpose of the book, the volume has a just claim for favourable consideration among the numerous members of its particular class B A E

Encyclopaedia of Veterinary Medicine, Surgery and Obstetrics Edited by Prof George H. Wooldridge (Oxford Medical Publications) Second edition In 2 vols Vol 1 *Veterinary Medicine* Pp xvi+836+xlix+2 plates. Vol 2 *Surgery and Obstetrics* Pp viii+837–1652+li+plates 3–6 (London Oxford University Press, 1934) 126s net

This encyclopædia, edited by Prof George H Wooldridge, professor of medicine and hygiene at the Royal Veterinary College, London, is written by a panel of forty-eight veterinarians, all recognised authorities in their special subjects Intended to be of use to general practitioners, owners of valuable animals and medical men interested in animal diseases, pathological detail is reduced to the minimum necessary for the understanding of clinical conditions In keeping with the growing importance of the subjects, new chapters on deficiency diseases and endocrinology have been introduced in this, the second, edition The work is comprehensive, authoritative, well illustrated, and arranged on a systematic as opposed to an alphabetical plan A table of contents, author and subject index make reference easy The work will be of real value to all interested in the more practical aspects of animal disease

The Indus Civilization By Dr Ernest Mackay Pp viii+210+16 plates (London Lovat Dickson and Thompson, Ltd, 1935) 6s net

This little book is the first of a series of handbooks of sectional archæology, authoritative but not technically advanced, intended for both the general reader and the student Dr Mackay has covered the main outline of the results of the excavation of the prehistoric sites of northern India and the relations, chronological and cultural, of the Indus civilisation adequately and with the lucidity to be expected from his intimate and detailed knowledge He appends a useful bibliography and an excellent series of small but very clear illustrations If the volumes which follow maintain the standard of the first—and they should if the names of the authors who are to contribute may be taken as a guarantee—this series will be a distinct addition to the literature of 'science made popular' in the best sense

The Differential Analyser

By PROF D R HARTREE, F R S, Beyer Professor of Applied Mathematics, University of Manchester

PURPOSE

THE application of mathematics to problems both of pure and applied science often leads to differential equations which have no formal solution in quadratures or in terms of tabulated functions, but for which numerical values of the solutions are required Until recently, the only available methods for evaluating the solutions of such equations were graphical methods, which are rather limited in scope and accuracy, and numerical methods, which are lengthy and require continual concentrated attention on the part of the worker, and rapidly become more laborious the more elaborate the equations So the development of a mechanical method, rapid, accurate, and applicable to a wide range of equations, is an advance of considerable importance, with applications to a wide range of problems of scientific and technical interest

Such an advance has been made by Dr V Bush, of the Massachusetts Institute of Technology, by the development of a machine known as the differential analyser, of which the first was designed and built there[1] The general idea of such a machine in the abstract is due to Lord Kelvin[2], but the practical design of a machine which could be made, and would work accurately when made, is due essentially to Dr Bush

A similar machine, with which the writer has been closely concerned, has been built at the University of Manchester, a short notice of the formal opening of this machine appeared in NATURE recently[3] Another such machine has quite recently been built at the University of Pennsylvania

CONSTRUCTION

The machine consists of a number of units which can be connected to shafts which drive them or are driven by them These shafts can be connected together by gearing in various ways, so that the relations between the rotations of the different shafts satisfy various differential equations. The adaptability of the machine as a whole, which is one of its most important features, depends essentially on the wide range of possibilities of such interconnexions

The essential units are those called integrators, since they carry out mechanically the operation of integration. Each of these is a continuously variable gear, consisting of a friction drive from a horizontal disc, which can rotate about a vertical axis, to a vertical wheel resting on it, the distance from the centre of the disc to the point of contact of the wheel with it can be varied by displacing the disc, the axle of which is carried in bearings in a carriage which can move along a pair of guide bars This displacement of the disc represents the integrand, the rotation of the disc represents the variable of integration, and the rotation of the wheel represents the result of the integration (Fig 1)

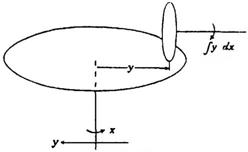

FIG 1 Principle of the integrator

It is essential for accurate operation of the machine that, in the rotational motion of the disc, there should be no slip between disc and wheel at the point of contact On the other hand, it is often necessary to make such connexions that a considerable amount of mechanism is to be driven by the rotation of the wheel, and the friction at the point of contact between disc and wheel is quite insufficient to provide the necessary torque on the shaft To avoid this difficulty, an ingenious mechanical servo-mechanism, called a torque-amplifier, has been developed by Dr Bush for this purpose Its operation is similar in principle to a power-operated capstan A band passes round a drum which is driven by an independent source of power and is continually running; one end of the band is fixed to an arm on the shaft carrying the integrating wheel, and the other to an arm on another shaft (output shaft) coaxial with it The rotation of the integrating wheel tightens the band and therefore increases the friction between it and the drum, and this additional frictional force on the band pulls round the arm attached to the output shaft, so that in effect the rotation of the integrating wheel simply operates as a control of the supply of power to the output shaft As developed by Dr Bush, this control is very delicate, the torque required to operate it being about one ten-thousandth of the torque required to drive the output shaft, and this small torque can be provided by friction between disc and integrating wheel without any danger of slip

Other units are input tables, used for supplying

to the machine information in the form of a functional relation between variables occurring in the equation A graph representing this relation is fixed to a board spanned by a movable bridge carrying a pointer which can be moved along it The position of this pointer along the bridge is controlled by rotation of a handle, which also drives the shaft to which the information expressed by the curve is to be transmitted The bridge is moved across the table by the operation of the machine, and an operator stationed at the table turns the handle to keep the pointer on the curve as the bridge moves

There is also an output table, similar in construction to an input table, on which the machine delivers the result in the form of a graph of the solution of the equation For a general survey of the behaviour of the solution, this is the most convenient form of record, but it is not suitable if quantitative results are required, on account of the distortion of paper with changes of temperature, etc., and also on account of the time required to measure up the curves An alternative recorder is a camera which takes photographs, at selected intervals, of a set of revolution counters which can be connected to the appropriate shafts.

In addition, there are differential gears which serve to add or subtract the rotations of two shafts, and 'front-lash units', the object of which is to compensate any backlash in the various drives This is achieved by a gear train arranged to give a small and adjustable angular advance of a driven shaft relative to a driving shaft, at each occasion on which the direction of rotation of the latter changes

The machine is driven by electric motors One motor drives the shaft the rotation of which represents the independent variable, and each pair of integrators has a motor driving their two torque amplifiers, one for each integrator The running of the machine is controlled by a set of switches placed conveniently for an operator who may be following a curve on an input table These switches operate contactors which control the supply of current to the various motors

A general view of the machine at the University of Manchester is shown in Fig. 2, in which the main component units are indicated

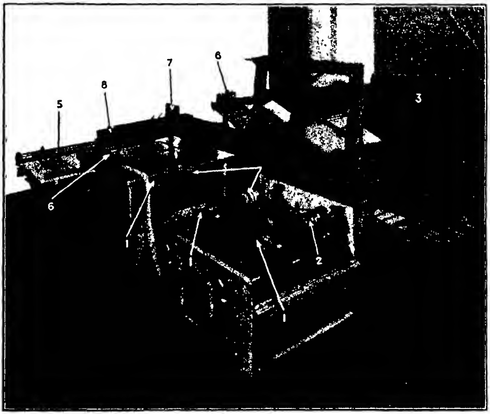

FIG 2 General view of the differential analyser at the University of Manchester 1, Integrators, 2, torque amplifiers, 3, input table, 4, special input table, 5, output table, 6, control switches, 7, revolution counters, 8, base for camera (camera not shown) Photograph by Metropolitan-Vickers Electrical Co, Ltd

OPERATION

The operation of the machine involves two processes. first that of setting up the inter-

connexions between the units in such a way that the relations between certain shafts satisfy the equation in question, and secondly the carrying out of an actual solution of the equation

The setting-up is first carried out in diagrammatic form, on paper, and the scales on which the rotations of shafts represent variables in the equation are decided At this stage, experience counts for a lot, in discovering how to put an equation on the machine, and in deciding between various alternative ways which may be possible The interconnexions on the machine are then set up from the diagram The initial conditions for the solution are usually supplied to the machine in the form of initial displacements of integrators

There are many equations which can be handled without any attention from an operator in the course of the running of the machine, beyond pressing the control switches Other equations require the use of one or more input tables, for each of which an operator is required as explained above

The process of setting up the machine may take from half a day to a day, but once it is set up, a solution may be obtained in ten to fifteen minutes, this time being practically independent of the complexity of the equation so long as it is within range of the machine, whereas the process of solution of a comparatively simple equation by purely numerical means would probably take an experienced worker four hours to a day of work which needs continuous careful attention, as, although it is of a routine nature, it is not altogether simple and straightforward, a more elaborate equation, or a less experienced worker, would require much longer

Use of the machine may thus not lead to a great saving of time when only a single solution of an equation is required, though even then there is considerable saving of mental labour of a routine kind But when a number of solutions of one equation, for example, solutions with different initial conditions, or different values of numerical coefficients occurring in it, are required, the time occupied in setting up the machine for the equation is a small proportion of the whole period concerned with work on that equation, and the total time required to obtain a specified set of solutions may then be reduced by a factor of 10 or 20 This very large saving of time, and the corresponding saving of mental effort, is important not only in dealing with problems which would in time be dealt with in any case, but even more in making it practicable to undertake extended investigations which without such mechanical assistance would be altogether too laborious and time-consuming.

Further, since the time and labour of mechanical solution does not increase appreciably with the complexity of the equations, whereas the time and labour of numerical solution does increase very considerably, the value of the machine increases rapidly with the complexity and range of equations within its capacity, and this increases rapidly with the number of units of which it is constituted A machine with eight integrators, for example, is very much more than twice as valuable as one with four integrators

APPLICATIONS

Since the differential analyser handles a mathematical situation without reference to the particular physical or technical problem which has given rise to that situation, the problem itself is largely irrelevant to it, but some problems to which it can be applied may be mentioned to indicate its range

(a) Atomic structure and properties

(b) Transients in electrical circuits containing elements with non-linear characteristics

(c) Performance of automatic control mechanism

(d) Propagation of radio waves in the Heaviside layer, regarded as a stratified medium

(e) Vibrations of systems with non-linear restoring forces

(f) Paths of electrified particles in the field of a magnet (for example, in connexion with the theory of the aurora and of cosmic radiation)

(g) Equilibrium and stability of stellar structures

By the nature of the case, the differential analyser provides a numerical (or graphical) solution of an equation with definite numerical values of coefficients in the equation, and of initial conditions, and cannot provide a general analytical solution, indeed, one of its virtues is that it can be applied to equations for which no such solution exists. Thus it does not seem likely to be of any great interest or value in purely mathematical fields, in which the interest, if any, in the solution of any equation lies in the general form of the solution, or in its formal analytical expression On the other hand, in physical and technical investigations, it is often the special solutions, and actual numerical values, which are required, and it may happen that even if there is a formal analytical solution, it is unsuitable for numerical evaluation So that it is mainly in connexion with such applications that the differential analyser is likely to be used

THE DIFFERENTIAL ANALYSER AT THE UNIVERSITY OF MANCHESTER

In general design and in many details, the differential analyser at the University of Manchester, which has been constructed by the

Metropolitan-Vickers Electrical Co., Ltd, follows closely Dr Bush's original machine at the Massachusetts Institute of Technology, but several modifications in detail have been made

The machine is being built in two sections, one of which is now complete This completed section comprises four integrators and two input tables, the output table, and a special camera designed and built by Messrs Newman and Guardia, Ltd, for the photographic recorder One of the input tables is of special construction, for handling equations describing the behaviour of a system in which the rate of change of a quantity at time t may depend explicitly on its value, or on the values of other quantities, at time $t - T$ (where the time-lag T may be constant or variable) as well as on their values at time t The second section, now under construction, will comprise four further integrators, making eight altogether, and probably four further input tables, and, as explained above, the greater range will very greatly increase the value of the machine

The construction of this differential analyser has been made possible, first through the great generosity of Mr Robert McDougall, deputy treasurer of the University, who first gave to the University a donation to cover the estimated cost of the first section, now completed, and has recently supplemented this by a further donation to cover the completion of the machine in accordance with the original estimates, secondly, by the friendly and generous co-operation of Dr Bush himself, who freely gave his drawings, and several suggestions for improvement, and helped greatly by his advice based on experience of construction and operation of his own machine, and thirdly, through the co-operation of Mr A P M Fleming, of Metropolitan-Vickers Electrical Co, Ltd, who undertook the construction of the machine, and of those members of the firm who have been concerned in its design, construction and erection

Royal Society Discussion on Supraconductivity

IN opening the Royal Society discussion on supraconductivity, Prof J. C McLennan referred first to new methods of helium liquefaction which have recently been developed In Prof F Simon's method, high pressure helium gas is cooled to liquid hydrogen temperatures and then allowed to expand through a valve, a small quantity of liquid helium being produced which is quite adequate for many types of experiments A second method, developed by Prof P Kapitza at Cambridge, applies to helium the method first used by Claude for the liquefaction of air, part of the gas doing external work in an expansion engine and so cooling the remainder below the inversion temperature of the Joule-Thomson effect, whence it can be liquefied by expansion

Prof. McLennan then discussed the rapid progress in the attainment of temperatures near the absolute zero made possible by the adiabatic demagnetisation method, the latest experiments of de Haas with potassium chromium alum having reached a temperature of 0·0044° on the scale obtained by measuring the magnetisation and using an extrapolated Curie Law to obtain the temperature. Progress is at the same time being made in the establishment of the thermodynamic scale in this temperature region. Prof W. H Keesom reported that the thermodynamic scale has been established down to 0·9° K. using the helium thermometer. Prof Simon reported the results of an ingenious method developed at Oxford in which the heat, dQ, required to warm up the salt from its lowest temperatures to its initial temperature is determined by using γ-rays to warm up the salt Since the entropy change, dS, on magnetisation can be calculated and the cooling is adiabatic, the temperature on the absolute scale is obtained from dQ/dS. The results show that the thermodynamic scale and the magnetic scale using iron ammonium sulphate do not differ by more than 10 per cent down to 0 08° K, but that below this temperature the thermodynamic temperature is greater than the magnetic temperature For these lower temperatures the shape of the specimen has a large effect on the magnetic temperature owing to the increasing importance of the demagnetising coefficient

Prof McLennan referred also to the prediction that at these low temperatures the effect of nuclear magnetic moments should become important, owing to the thermal energy becoming comparable with the energy of magnetisation due to nuclear moments Prof. Simon considers that it may be possible to use a two-stage demagnetisation process for the attainment of the lowest temperatures, the nuclear moments becoming effective in the second stage. Dr. Heitler's prediction in the discussion that it would take a year for equilibrium to be set up owing to the smallness of the nuclear interaction failed to shake Prof. Simon's determination to try the experiment

The production of these low temperatures has

extended the list of supraconducting metals, and Prof McLennan gave a list of fifteen such metals with transition temperatures ranging from 0 40° K to 9 2° K As Mr J D Bernal pointed out in the discussion, these metals lie in Groups IVa, Va, VIa and IIb, IIIb, IVb of the Periodic Table, and in no others A number of supraconducting alloys, on the other hand, have been discovered, such as the gold-bismuth series, the components of which lie on either side of these groups and are not themselves supraconducting Mr Bernal considers that supraconductivity has little to do with the crystal lattice, since supraconductors of many crystal types are found Prof Keesom pointed out, however, that one of the varieties of tin is supraconducting whilst the other is not

Prof McLennan referred next to the remarkable phenomenon of the 'Meissner effect' When a metal sphere placed in a weak magnetic field is cooled down to the temperature at which it becomes supraconducting, the lines of magnetic induction move out of the sphere at the transition temperature, and the field outside takes precisely the form which would be expected if $B=0$ in the interior of the sphere, supraconductivity being thus characterised by the conditions $B=0$, $E=0$ When the tangential component of the magnetic field reaches the critical value for supraconductivity, the lines of force re-enter and supraconductivity disappears

Dr Meissner described a number of further experiments on this phenomenon Measurements have been made of the magnetic field in the space round a supraconducting cylinder placed with its axis perpendicular to the field The lines of force in the hollow of the cylinder do not move out, but on the contrary are increased in density when the cylinder becomes supraconducting, and on removal of the external field these lines of induction remain almost unchanged, thus imparting a magnetic moment to the cylinder As the external field is increased, the normal component of the field outside the cylinder increases, showing increasing penetration of the lines of force

Dr K Mendelssohn described experiments on this phenomenon which show that only in the ideal case of a perfectly pure metal and a perfect lattice do all the lines of induction disappear from the supraconducting sphere When the metal is impure, some of the lines of induction appear to be 'frozen in', a rod of moderately pure lead retaining about ten per cent of the flux The results can be explained, he considers, by the formation of annular supraconducting regions in which the flux is 'locked', the formation of such regions being aided by the effect of impurities in increasing the local transition temperature for supraconductivity.

Since a state of zero magnetic induction is equivalent to a diamagnetic susceptibility of $-\frac{1}{4}\pi$, experiments on the force exerted by an inhomogeneous magnetic field on a lead sphere should show an enormous increase in the pull when supraconductivity sets in. An experiment of this type carried out at Cambridge was described by Mr Shoenberg, the force for weak fields corresponding precisely to that expected As the field is increased, the susceptibility remains constant until the field at the equator reaches that critical for supraconductivity At this point, the lines of force begin to penetrate the sphere, and the susceptibility decreases to zero as the main part of the external field reaches the critical value

Considerable discussion took place on the evidence provided by low temperature phenomena on the behaviour of electrons in metals Thus, for supraconducting metals of high purity, the thermal conductivity is increased when the supraconductivity is destroyed by a magnetic field, in agreement with the hypothesis that the supraconducting electrons are an appreciable fraction of the ordinary conduction electrons and that they become available for heat transfer when supraconductivity is destroyed On the other hand, the thermal resistance should tend to zero near absolute zero, whereas the actual resistivity shows a minimum and begins to rise again at the lowest temperatures, one striking case being reported by Prof. Simon in which the thermal resistivity of a copper rod became equal to that of glass at room temperature

Prof Keesom described experiments on the specific heats of metals which show the presence of an additional heat capacity due to the electrons, increasing linearly with temperature in the case of tin up to 9° K. Prof N F Mott considers that additional evidence for the heat capacity due to electrons is provided by the specific heat of metals such as nickel at temperatures of 1000° K, where C_v is greater than the Debye value of $3R$ by at least $1R$, the maximum contribution for electrons being $3/2R$

Further experiments on the effect of electrons in metals were demanded by Prof R de L Kronig, who suggested that the reflecting power of metals should show measurable changes on transition from the supraconducting to the conducting state Changes should also occur in the fine structure of X-ray absorption edges and in the transmission of wireless waves by thin metal films

Prof L. Brillouin and Dr F London discussed the state of the theories of supraconductivity The former emphasised the facts which a theory has to explain, and referred to a proof by Bloch that no classical theory can explain a stable state of persistent currents. Dr. London opened a new

attack on the problem by refusing to consider supraconductivity as the limiting case of ordinary conductivity and by considering it as a more elementary state in which the whole metal behaves like a large diamagnetic atom. A new equation, λC curl $J = -H$, relating current density and magnetic field, is postulated, this assumption replacing Ohm's Law in a supraconductor and leading directly to a solution in which stable persistent currents are possible, these currents being confined to a depth of 10^{-5} cm. below the surface of the conductor.

Obituary

Prof. H. M. Macdonald, O.B.E., F.R.S.

HECTOR MUNRO MACDONALD was born in 1865 at Fearn, Ross-shire, and educated at Tain Academy, Aberdeen Grammar School and the University of Aberdeen, proceeding in 1886 to Clare College, Cambridge, and taking the Mathematical Tripos in 1889. The list of Wranglers was one of considerable distinction: Sir Gilbert Walker was senior, Sir Frank Dyson second, Macdonald fourth and A. S. Ramsey (president of Magdalene) sixth. He was soon elected to a fellowship at Clare, and in 1891 was Smith's Prizeman.

During Macdonald's formative period, the professorial chairs at Cambridge were occupied by Stokes, Adams (the discoverer of Neptune), Cayley, J. J. Thomson and G. Darwin; while of the other teachers, he seems to have owed most to Routh, Hobson, Glazebrook and Larmor. But perhaps his greatest debt was to Verdet's "Leçons d'optique physique", Maxwell's "Electricity and Magnetism" and the works of Horace Lamb and the third Lord Rayleigh.

Macdonald's first published papers were on hydrodynamics and the mathematical theory of electricity—waves in canals, electrical distributions on conductors of various shapes, and self-induction. In 1897, however, he began to write on pure mathematics—the relation between convergent series and asymptotic expansions, the zeros and the addition theorem of Bessel functions, various Bessel integrals, spherical harmonics and Fourier series. In the paper on the zeros of the Bessel functions (*Proc. Lond. Math. Soc.*, **29**; 1898), he gave the result since known as Macdonald's theorem, that the number of zeros of a function $f(z)$ in the region bounded by a contour at each point of which $|f(z)| =$ a constant, exceeds the number of zeros of the derived function $f'(z)$ in the same region by unity, the function $f(z)$ being supposed analytic in the region.

Macdonald's reputation as a discoverer was, however, chiefly due to a third group of researches, which began with his Adams Prize essay of 1902 on electric waves, and was continued in a paper of 1903 on the bending of electric waves round a conducting obstacle, two memoirs on the diffraction of electric waves round obstacles (*Phil. Trans. Roy. Soc.*, 1911–12), several papers on the diffraction of light by opaque prisms, straight edges, etc. (*Proc. Lond. Math. Soc.*, 1913–15), and a series of papers (*Proc. Roy. Soc.*, A) from 1914 onwards on the transmission of electric waves round the earth's surface.

In 1905 Macdonald left Cambridge on being appointed to the chair of mathematics in his old University of Aberdeen. The value of his work was recognised by the fellowship of the Royal Society in 1901, an honorary fellowship of Clare in 1914, a Royal Medal of the Royal Society in 1916, the presidency of the London Mathematical Society in 1916–18, and the Honorary LL.D. of Glasgow in 1934. During the last thirty years of his life, he took an active part in the administrative work of the University of Aberdeen and of educational institutions in the north-east of Scotland, and was almost invariably one of the delegates appointed to any conference of representatives of the four Scottish Universities. In recognition of his scientific eminence and public services, a subscription portrait was presented to the University of Aberdeen in 1933.

Macdonald never married. He died after a short illness on May 16, 1935.

E. T. WHITTAKER.

Prof. W. R. Hodgkinson, C.B.E.

ON April 8, at Blackheath, died, at eighty-three years of age, Prof. William Richard Hodgkinson, one of the older school of chemists, whose interests in chemistry covered a wide field. Born at Sheffield in 1851, and educated at the Royal Grammar School there, he early came under the influence of Sorby, the father of metallography, and to this is to be traced his later work on metals and their treatment.

Having gained a scholarship to the Royal School of Chemistry and of Mines in London, Hodgkinson studied geology, and under Sir Edward Frankland organic chemistry, before proceeding to the University of Wurzburg, where his natural feeling for research was stimulated by Prof. Wislicenus, whose textbook on "Organic Chemistry" he translated. On returning to England his investigations at the Royal College of Science were mostly in organic chemistry, and in this branch of chemistry he published papers on such subjects as the action of the alkali metals on organic bodies, with W. H. Perkin, junr., and on organic bases and on naphthalene derivatives, with Dr. W. Limpach, whose sister he married nearly fifty years ago.

After a short period at the Royal Military Academy, Hodgkinson became lecturer in chemistry and metallurgy at the Ordnance College, and later professor of chemistry there, retiring in 1921 after thirty-one years of service in the College (now the Military College of Science). Most of Hodgkinson's work was thus carried out at Woolwich, and much of it was directed to Service problems and to training many generations of gunner officers, who look back to this

period of their career with much affection for their teacher, but the feature which impressed itself on all who knew him was the exuberance of his mind in suggesting new investigations Of such as have been published may be mentioned his researches on the reducing properties of hydrazine and on hydrazine nitrate as an explosive, and on the carburisation of metals by acetylene He edited and enlarged a textbook of chemistry known throughout many editions to generations of students -Valentin-Hodgkinson's "Qualitative Chemical Analysis"

It will thus be seen that as distinct from modern specialisation, Hodgkinson had an equal interest in and was fruitful in suggestion in organic, inorganic and metallurgical chemistry and became an authority on the chemistry of explosives, writing the Service treatise on that subject. For his work during the War in advising on and directing certain manufactures, he was made a C B E in 1918

Hodgkinson's personality endeared him to all, and his interests were not confined to his main subject Thus he was chairman of the Blackheath School of Art and took a live interest in its work, for he himself was a wood carver of great ability He took part in the local government and in the educational affairs of the neighbourhood of Blackheath, and was founder of the Radium and of the Imperial College Lodges of Freemasonry

Prof Hodgkinson leaves a widow, a son (Capt C. R Hodgkinson, R A) and two daughters, one married to Mr T. Morson A much loved son was killed in the War R. ROBERTSON.

PROF WILHELM KOLLE

BY the death of Prof. Wilhelm Kolle at sixty-six years of age, on May 10, Germany loses one of her foremost bacteriologists, whose reputation was world-wide. Qualifying in medicine in 1892, Kolle entered the Institute of Infectious Diseases in Berlin in 1893 and became assistant to Robert Koch By virtue of his position and work in that Institute, he was invited in 1897 by the Cape Government to conduct a scientific expedition in South Africa for the study of leprosy and rinderpest, and in 1900 was sent on a similar mission by the Egyptian Government to the Sudan, where he founded a laboratory at Khartoum. He was afterwards for a time professor of hygiene and bacteriology in the University of Berne, and in 1915 succeeded Paul Ehrlich as director of the Institute for Experimental Therapy in Frankfort-on-Main, where he remained for the rest of his life

On plague, cholera, leprosy and rinderpest, Kolle made important contributions He was the first to prepare an effective antiserum for an ultra microscopic virus, that of rinderpest or cattle plague, and the simultaneous method of protection against this disease with virus and immune serum was due to him and to the late Sir George Turner, formerly Medical Officer of Health for the Transvaal. In association with R. Otto, he devised a method of immunisation against plague with attenuated culture of the plague bacillus, and with R. Pfeiffer evolved a method of protection against cholera by means of dead culture. At Frankfort, where he was also director of the Georg Speyer-Haus research institutes, Kolle carried out investigations upon syphilis and spirochætes, and was the first to produce the drug 'neosalvarsan', and also another drug, 'spirocid', the forerunner of stovarsol, which was discarded on account of toxicity

Kolle's literary activity was prodigious, and he was the author in collaboration with Wassermann of the classical handbook of pathogenic micro organisms, the last edition of which runs to ten volumes, as well as of a handbook on salvarsan treatment, a textbook of clinical methods of investigation, and one on experimental bacteriology.

R T HEWLETT

PROF V POSEJPAL

WITHIN a few weeks of the death of Prof B Brauner, Czechoslovak science sustained a second heavy loss Prof Václav Posejpal, professor of experimental physics at the Charles University of Prague, died suddenly on April 8. He was born at Chlumec in Moravia on December 20, 1874, and studied at Hradec Kralové before going to Prague and taking his degree in natural sciences in 1900. He selected for his dissertation a thesis on Fourier series After a period in Paris, studying certain Volta effects on magnetic fields, he returned to Prague, becoming *Privatdocent* at the University in 1910 In 1919 he was installed as professor of physics, and was Dean of the Faculty of Sciences in 1929–30.

Prof. Posejpal was one of the leading Central European research workers in experimental physics, and carried out noteworthy investigations on such subjects as the refractivity of gases at low pressures, fluorescence phenomena, X-ray spectroscopy and resonance. He also contributed to our knowledge of the ether and the neutron. Most of his work appeared in Czech scientific journals, but he also published papers from time to time in the *Comptes rendus* of the Paris Academy of Sciences and in German publications.

Prof. Posejpal was a Chevalier of the Legion of Honour and honorary member of many physical societies. He was general secretary of the Czechoslovak National Research Council and a vice-president of the International Union of Pure and Applied Physics. His colleagues and students held him in high esteem and he will be greatly missed in scientific circles in Czechoslovakia. He was known to a wider public through his popular broadcasts on scientific matters.

Prof Posejpal was keenly interested in winter sports and frequently conducted parties of friends and students on ski-ing expeditions to the High Tatras and to the Austrian Alps. J. G. F. D.

MR. R. E. RICHARDSON

THE Middle West of the United States lost an outstanding ichthyologist and aquatic biologist by the death on April 14 of R. E. Richardson, best

known for his work on the monumental volume, "The Fishes of Illinois", written in collaboration with S A Forbes, and for his researches and publications on the use of organisms as indexes of the degree of pollution of natural waters

Robert Earl Richardson was born at Brighton, Illinois, on November 28, 1877 He was the son of Robert and Emily Dickerson Richardson, members of pioneer families of Macoupin county After preparatory work at De Pauw University, he graduated from the University of Illinois in 1901 He was elected a fellow in zoology there and received the M.A. degree in 1903. He was co-author with David Starr Jordan in a series of papers on the fishes of Formosa, Japan and the Philippines From 1909 until 1922 he had charge of the floating laboratory of the Natural History Survey on the Illinois River. His interests in science were wide and he read widely in other fields--literature, biography, history and finance Owing to delicate and uncertain health, he lived a quiet and secluded life

DAVID H THOMPSON.

News and Views

King's Birthday Honours

THE following names of men of science and others associated with scientific work appear in the list of honours conferred by the King "on the occasion of his Majesty's Birthday, and in commemoration of the completion of the twenty-fifth year of his Majesty's reign". —*O M* Sir Frederick Gowland Hopkins, in recognition of his eminent services to biochemistry, especially in connexion with the discovery of vitamins *Viscount*. Lord Bledisloe, lately Governor-General of New Zealand *G C M G.*: Sir Henry Birchenough, president of the British South Africa Company and chairman of the Beit Trustees *G B E* Sir George Newman, lately chief medical officer, Ministry of Health and Board of Education *K C B* Dr G C Simpson, director of the Meteorological Office *K B E* Prof J C McLennan, professor emeritus and visiting professor of physics, University of Toronto, Dominion of Canada, for fundamental discoveries in physics and scientific services *D.B.E.*: Mrs. M M. Ogilvie Gordon, vice-president of the International Council of Women and former president of the National Council of Women *Knights* Mr N Ashbridge, chief engineer of the British Broadcasting Corporation; Prof. J. Barcroft, professor of physiology, University of Cambridge; Prof A J Hall, emeritus professor of medicine, University of Sheffield, for distinguished service to medicine and medical science, with special reference to problems of the health of industrial workers, Mr J. H M Horne, vice-chairman, Advisory Council to Department of Agriculture for Scotland; Dr. L L Fermor, director of the Geological Survey of India; Mr. H H Humphries, city engineer of Birmingham, president of the Town Planning Institute; Mr. P. P. Laidlaw, pathologist to the Medical Research Council, for distinguished service to medical science; Dr. S L Pearce, engineer-in-chief of the London Power Company, Ltd.; Dr. C. L. Woolley, for services to archæology

C.B.: Dr. W. T Calman, keeper of zoology, British Museum (Natural History), president of the Linnean Society of London; Dr. F. S. Sinnatt, director of fuel research, Department of Scientific and Industrial Research; Mr. H. E. Wimperis, director of scientific research, Air Ministry. *C M.G.*: Dr G S. H. Barton, Deputy Minister of Agriculture, Dominion of Canada; Mr. E Harrison, director of agriculture, Tanganyika Territory; Mr E. J. Wortley, director of agriculture, Trinidad *C.I E.*: Lieut-Colonel B Higham, chemical analyser to the Government of Bombay, Lieut-Colonel R. Knowles, professor of protozoology and secretary of the Calcutta School of Tropical Medicine *C.B E* Dr. W F Bewley, director of the Experimental and Research Station of the Ministry of Agriculture and Fisheries at Cheshunt; Colonel W. MacC Burden, chief superintendent of the Research Department, Royal Arsenal, Woolwich, Dr C E Cook, chief protector of aborigines, Northern Territory, Commonwealth of Australia; Dr. G W M. Findlay, member of the scientific staff of the Wellcome Research Institution, London, for services in connexion with the study of prevention of yellow fever, Prof. A Fowler, emeritus professor of astrophysics, Imperial College, South Kensington, for services to science, Mr E Marsden, secretary, Department of Scientific and Industrial Research, Dominion of New Zealand; Dr W L. Miller, president of the Royal Society of Canada; Mr. F T. Shutt, lately Dominion Chemist, Dominion of Canada, Dr N. V Sidgwick, reader in chemistry at the University of Oxford, for services to science *I S.O*: Mr W Dallimore, keeper of museums, Royal Botanic Gardens, Kew. *O B E.*: Mr. C E Blaker, principal, Government School of Engineering, Rasul, Punjab; Prof G B. Bryan, professor of physics, Royal Naval College, Greenwich; Mr. G. R King, lately principal of the Gordon Institute of Technology, Geelong, State of Victoria; Mr. H. S Hensman, superintendent, Government Mental Hospital, and lecturer in mental diseases, Medical College, Madras; Dr W. A. Richardson, principal of the Technical College, Derby; Mr A. Walter, director, Meteorological Service, East Africa; Mr H. Wolfe, deputy director of agriculture, Kenya *M.B.E.*: Mrs. N. L. L. Alcock, plant pathologist, Department of Agriculture for Scotland; Mr W Barnicot, secretary of Rothamsted Experimental Station for Agricultural Research; Mr. E O. Sampson, deputy conservator of forests, in charge Dangs Forests and *ex officio* Deputy Political Agent for the Dangs, Bombay; Mr. G. Walton, assistant agriculturist, Northern Rhodesia.

New Foreign Members of the Linnean Society

THE four recently elected foreign members of the Linnean Society are all botanists Dr A F Blakeslee, assistant director in the Department of Genetics at the Carnegie Institution of Washington, is not only an outstanding geneticist but was also the discoverer of the phenomenon of heterothallism in the Mucorineæ, which has had a most profound influence both on the study of fungi and on theories of sex Prof P A Dangeard, until lately professor of botany at the Sorbonne, is known chiefly as a mycologist and cytologist though he has covered a very wide field in botanical research: he has been responsible for *Le Botaniste* since 1889, contributing the whole of many of the volumes Prof G Senn, director of the Botanical Institute at Basle, is a botanist of many sided activities At first mainly interested in algal flagellates, he turned his attention to the physiology of the plant cell, studying particularly the chromatophore More recently he has written a valuable treatise on the botany of Theophrastus He has also worked on alpine plants Prof C Raunkiaer, formerly professor of botany at Copenhagen, has considerably influenced ecological thought by his work on growth forms He has been chiefly interested in phytogeography, morphology, taxonomy and statistical methods His papers have recently been translated into English under the title "The Life Forms of Plants and Statistical Plant Geography".

Dr. Herbert Smith

THE Principal Trustees of the British Museum have appointed Dr George Frederick Herbert Smith to be keeper of mineralogy in the British Museum (Natural History), in succession to Dr L J Spencer, who retires on July 7 next Dr Herbert Smith was born in 1872. He was educated at Winchester, and at New College, Oxford, where he held a Winchester scholarship He took a first in Mathematical Moderations (1892), Final School of Mathematics (1895) and Natural Science School, Physics (1896) He entered the Museum as an assistant in the Department of Mineralogy in 1897, and soon became recognised as an authority on mineralogy and crystallography, and wrote numerous papers on these subjects His book on gem stones has for many years been used as the standard textbook in the jewellery trade He invented the three-circle goniometer, and a hand-refractometer for the determination of gem-stones Dr Herbert Smith's interest in general civil service problems led to his appointment in 1921 to the post of secretary of the Museum, which he has since held He is honorary secretary of the Society for the Promotion of Nature Reserves, and chairman of the Wild Plant Conservation Board

Franklin Institute Medals Awards

SCIENCE SERVICE of Washington, D C, states that the Franklin Institute, Philadelphia, has recently awarded Franklin Medals to Prof. Albert Einstein for his researches on relativity and the photo-electric effect, and to Sir Ambrose Fleming for his work on the thermionic valve A certificate of merit has been awarded to G S Kelley, of New York, for reducing rock dust hazard The following medal awards have also been made for the work indicated Edward Longstreth Medals to Edmund Bruce of the Bell Telephone Laboratories (short wave radio antennæ), Howard D Colman and B A Petersen of Rockford (an automatic spooler); P Davey of New York (a portable balancing device), and K B McEachron of the General Electric Co, Pittsfield (for developing the material thyrite): John Price Wetherill Medals to Dr F F Lucas of the Bell Telephone Laboratories (photomicroscopy), R E Naumburg of New York (an unusual mechanical apparatus), W H Shortt and F Hope-Jones (precision clocks), Dr J E Shrader of Drexel Institute, Philadelphia (a vibration-measuring instrument); Dr L B Tuckerman of the National Bureau of Standards (an optical strain gauge), H E Warren of Ashland, Mass (the telechron used in electric clocks) Walton Clark Gas Medal to F. J West of Manchester (work in the gas industry) Louis Edward Levy Medal to Dr H L Hazen of the Massachusetts Institute of Technology (mechanical robots or servo-mechanisms).

The Quetta Earthquake of May 31

WITHIN little more than sixteen months, the Indian Empire has been visited by another great destructive earthquake. On May 31, at about 2 45 a m (probably about 9.15 p m. on May 30, G M T), the cities of Quetta, Mastung and Kalat were almost entirely razed to the ground In Quetta alone, the loss of life is estimated at more than 20,000 The region is one that has frequently been disturbed by destructive earthquakes. The valuable report by Mr W D West on those of August 25 and 27, 1931, has recently been noticed in NATURE (April 27, p 661) The earlier shock had its centre near Sharigh, which lies 39 miles east of Quetta, the later and stronger near Mach, 26 miles south-east of the same city In the recent earthquake, the epicentral area—if we may take it as lying along the Quetta-Mastung-Kalat line—is roughly parallel to the zone joining Sharigh to the main part of the Mach area, and about 50 miles to the west. It is also parallel to the main structural lines of the country, and especially to the great boundary fault, 45 miles to the west, that runs along the west side of the Khojak Range for a distance of at least 120 miles It was to a nearly horizontal shift of about 2¼ ft along this fault that the severe earthquake of December 20, 1892, was due

Revision of Ordnance Survey Maps

WE are glad to note that the Minister of Agriculture has appointed a committee, under the chairmanship of Mr. J. C. C Davidson, Chancellor of the Duchy of Lancaster, to consider the measures necessary to accelerate the revision of the Ordnance Survey maps The maps in question are the large-scale plans, that is, the 25-in., the 6-in. and, in some cases, even those on larger scales, but chiefly those

mentioned The small-scale maps, namely, those on the 1-in and smaller scales, present no problem The large-scale plans, which are numbered by tens of thousands, have been gradually getting very much out of date This is mainly due to two causes: the action of the Geddes Committee of 1922 in recommending further reductions in an already reduced department, and the great alteration in the countryside caused by the expansion of the built-up area and the spread of 'ribbon development' There is also the further difficulty that, simultaneously with the enforced slowing up of revision, there has been an increased demand for the large-scale plans for town planning and for land registration It is clearly high time that the whole matter was examined Many interests are involved, as is indicated by the fact that no fewer than six public departments are represented on the Committee The question is somewhat urgent, and it is to be hoped that the Committee may be able to report speedily, for every month the arrears become more serious There is one curious item in the terms of reference; the Committee is to "review the scales and styles of Ordnance Survey maps placed on sale". It is not to be desired that we should enter again upon the 'battle of the scales' which was happily decided more than two generations ago. Nothing has happened since then to throw doubt upon the wisdom of the choice of the 25 in scale as that of our principal large-scale plans That old 'battle of the scales' lasted from 1840 until 1863, and since the latter date the country has enjoyed, in this matter, the great advantage of an uninterrupted, continuous policy

Civil Aircraft in the Royal Air Force

THE Air Ministry has acquired a De Havilland *Dragon Rapide* and an Avro *Ava*, two well-known commercial types of aircraft, for R.A F. use Such purchases indicate two possible lines of attack on the problem of rapid expansion recently announced. The degree of military usefulness of such machines, and the amount of modification necessary, can be studied in actual experiment by the R A.F personnel concerned. Also the more immediate problem of obtaining a sufficient supply of machines for training and flying practice, for the increased establishment under the new R.A.F. expansion scheme, will be helped, if civil machines are found suitable, and can be built immediately in factories already in production of them. It is understood that the first two of the five new training schools are to be opened this month, each school having the equivalent of three squadrons. Thus the problem of equipment is not only to supply these, but also a progressively increasing number of machines for the use of these pupils as they pass out into the service. It has to be discovered whether it is best to allow constructing firms to accelerate the production of their own aircraft, modified to R.A.F. requirements, or to change them over to contracts to build other machines specifically designed for R.A.F. work. Large contracts have also been placed for the construction of aeroplane hangars in various places.

German Commercial Airship Plans

THE new Zeppelin, Airship *L Z. 129*, is now reported to be complete in skeleton, and work on covering has commenced. It is hoped to launch it at the end of July When completed it will be the largest airship in the world It is 813 ft in length, 135 ft maximum diameter, and has gas capacity of 6,720,000 cubic feet Dr Eckener says that he intends to build three further ships for routes across the North Atlantic, South Atlantic, and to India and Batavia, that will operate under American, German and Dutch control respectively The German operating base will be changed from Friedrichshafen to Frankfort, which is not only more convenient for commercial traffic but is also at a lower altitude The loss of available lift due to starting from the higher altitude of Friedrichshafen is estimated to be about three tons for the *L Z 129*. Arrangements have also been completed for the construction of a mooring mast and gas plant at Seville, in conjunction with the Atlantic routes A new operating company, in which the German Government is said to be interested, is being formed with a capital of about £835,000.

The Admiralty Magnetic Survey Ship

AT the sixteenth annual meeting of the American Geophysical Union, held at Washington on April 26, the following resolution was adopted "WHEREAS, The magnetic survey of the oceanic areas, carried on for 25 years by the Carnegie Institution of Washington, was brought to a sudden end by the destruction of the *Carnegie* at Apia, Western Samoa, November 29, 1929, in the course of a cruise designed to determine the secular change of the Earth's magnetism in all oceans, and WHEREAS, It is of very great importance, not only for the practical needs of the navigator but also for the effective study of the Earth's magnetism, that these observations be resumed at an early day, and WHEREAS, It has been announced that the British Admiralty has decided to build a non-magnetic vessel, designed primarily for securing magnetic data at sea, therefore be it RESOLVED, That the American Geophysical Union is highly gratified at this action of the British Government, assuring, as it does, the continuance of the ocean magnetic work, and expresses the hope that the construction and equipment of the vessel may be pushed to a speedy conclusion, and be it further RESOLVED, That a copy of this resolution be sent to the British Admiralty, to the Astronomer Royal, and to the Chairman of the British National Committee for Geodesy and Geophysics" In transmitting this resolution, Dr Isaiah Bowman, chairman of the National Research Council, writes, "All geophysicists must extend grateful thanks to the British Admiralty in making possible the further accumulation of data so essential to the needs of navigators and of scientific enquiry".

Noise Abatement Exhibition at the Science Museum

ON May 31, the Prime Minister opened the Noise Abatement Exhibition which has been organised by

the Anti-Noise League and is being held at the Science Museum, South Kensington, during this month. The opening ceremony was held in the lecture theatre, and was attended by some two hundred guests The chair was taken by Lord Horder, chairman of the Council of the Anti-Noise League Mr MacDonald in his speech opening the exhibition said that formerly a person who confessed that he was troubled by noise was put down as an irreparable crank; but now it is rightly regarded that noise is something that ought not to be tolerated by any decent man or woman. He suggested that their campaign against nerve jarring should be regarded as a great movement in aestheticism It is the duty of all to co-ordinate in the protection of life from jars of the eye and the nerves- jars of the complete human personality. Sir Henry Richards, chairman of the Executive Committee of the Anti-Noise League, in moving a vote of thanks to the Prime Minister, said that the League is an educational body and the exhibition is intended to show to the public the means of escape from noise The Prime Minister made a short tour of the exhibition and inspected among other things a silenced pneumatic road drill, a silenced motor-cycle engine, a ripple tank illustrating the behaviour of sound waves from a speaker in the House of Commons and several models demonstrating the scientific principles of the reduction of noise from machinery and in buildings

The Health of Sunderland and County Durham

DR G F WALKER, of Sunderland, in a letter to *The Times* last December, made an appeal that the deterioration of health of a section of the population in Sunderland and adjacent districts in County Durham, where unemployment has been severe and prolonged, was serious, and deserved more national consideration. In consequence of statements made in Dr. Walker's letter, the Ministry of Health instituted an inquiry by Dr Pearse, Ministry of Health, Dr Glover, Board of Education, and Mr Grant, Ministry of Health, whose report has now been issued ("Report of an Inquiry into the Effects of Existing Economic Circumstances on the Health of the Community in the County Borough of Sunderland and certain districts of County Durham London H M Stationery Office, 1935 9*d.* net) The matter of this report is too lengthy to quote in detail, but is summarised in the concluding paragraph While admitting that there may be some slight deterioration of health and small increase in the incidence of certain diseases, the investigators state that "We are unable to accept Dr. Walker's statement that there has been in this area a 'substantial and progressive deterioration in public health' ".

Technological Advances of the Past Twenty-five Years

SIR FRANK SMITH, secretary of the Department of Scientific and Industrial Research, spoke on June 3 at a special Jubilee luncheon, held under the auspices of the Society of Engineers, on "Some Significant Technological Achievements of the King's Reign". Sir Frank dealt with four outstanding types of achievement of the period. The first was the advances in medicine which have prolonged our lives, the second was the more complete harnessing of the electron, an achievement which has given birth to industries unknown in 1910, the third was the fixation of nitrogen, an achievement which has overthrown the menace to our food supplies resulting from diminishing quantities of Chile nitrate; and finally, the production of new steel cutting tools, which has largely affected mechanisation, the price of manufactured goods and the leisure of man. Speaking of the industrial applications arising from the discovery of the electron, and the researches of Sir J. J Thomson and Lord Rutherford and others on the structure of the atom and on matter in general, Sir Frank said: "When the King came to the throne there was not one listener in the world, for there was no broadcasting station To-day in this country alone there are over 7 million people with licensed receivers There are millions of thermionic valves in use, and on his Jubilee day the King spoke via millions of thermionic valves to hundreds of millions of his subjects The radio engineer was in charge, and by the simple operation of switches, millions and millions of electrons played the parts arranged for them beforehand." The turnover in the radio broadcasting industry, which did not exist twenty-five years ago, was more than 20 millions sterling last year. The harnessing of the electron has been, in Sir Frank's opinion, one of the greatest achievements of the King's reign. It enables one person to speak to and be heard by the whole of the civilised world, it has increased entertainment and amusement through the 'talkies', and it has enabled our homes, our roads and our public buildings to be illuminated in a manner which many would have thought impossible twenty-five years ago

British Standards Institution

THE annual meeting of the British Standards Institution was held on May 28, with Dr. E F Armstrong in the chair, who, in presenting the report, said the year's work showed marked progress in every section. He laid stress on the fact that more than 150,000 copies of the British Standard Specifications have been sold and distributed during the year, an increase over last year of 23,000, and that there are now 700 committees holding more than 1,000 meetings a year, the total membership exceeding 5,000. The machinery of the B.S I. is such that no section of industry need fear that its considered views will not receive the fullest consideration, or that a British Standard Specification would be issued in the face of soundly based objection. Moreover, it has been definitely stated that the Institution does not contemplate setting itself up as a testing authority. Mr. W. Reavell, a past-president of the Institution of Mechanical Engineers, has been elected chairman for the ensuing year. He was one of the first to recognise the necessity for the co-ordination of the work of mechanical standardisation, in which the Institution of Mechanical Engineers is taking a leading part. Perhaps one of the most important results of the year's work is the increasing success of the inter-Imperial co-operation which is now so firmly

established. Australia has a standards organisation with 500 committees manned by more than 4,500 individuals, and during the past year 75 industrial standards have been issued and 20 more are out for public criticism. British Standard Specifications are good propaganda for British trade, and it is to be noted that more than 12,000 copies have been sent to diplomatic and trade commissioners in all parts of the world, so that they may maintain complete sets which may be consulted by those desiring information regarding British products, as represented by British Standard Specifications. The Government continues its whole-hearted support of the B.S.I. as the national standardising body in Great Britain.

Cider Tasting Day at Long Ashton

THE Open Field Day at the Research Station, Long Ashton, near Bristol, was held on May 2. A large and distinguished company of growers, brewers, men of science and administrators met to exchange views, inspect the laboratories and outdoor plots, and to exercise a discretionary taste upon the samples of cider prepared under controlled conditions by the National Fruit and Cider Institute. Representatives from Canada, South Africa, India, and the United States were present. The function has retained its atmosphere of informality and free intercourse throughout its thirty years, in spite of the fact that visitors have increased in number about a hundred-fold since the first meeting of twenty-five members. The desire to take full advantage of the educational opportunities of the day has also grown. The ciders of 1934 were definitely above the average in quality, but were slightly inferior to the superlative product of the previous year—one cannot expect equal quality from two heavy crops in succession. An exhibit of centrifuging as a method of controlling fermentation attracted much interest, whilst experiments and outdoor demonstrations on pomology, plant nutrition, fruit breeding, economic mycology and entomology, willow culture and fruit and vegetable preservation, were also shown. The Agricultural Advisory Centre, Berkeley Square, Bristol, and the National Mark organisation provided additional exhibits.

Soil Research in Scotland

AT a Scottish joint meeting of the Chemical Society, Institute of Chemistry and Society of Chemical Industry held in Aberdeen on May 17–18, at which Prof. Alexander Findlay presided, the work being carried out at the Macaulay Institute for Soil Research provided the subject for discussion. Dr. Ian M. Robertson read a paper entitled "The Agricultural Utilisation of Peat Land", in which the geology of peat formation, the physical and biological properties of peat and their relation to land reclamation were described. Members of the three Societies had an opportunity to visit the Macaulay Institute for Soil Research on May 18, when the Director, Dr. W. G. Ogg, and his staff, described the particular branches of soil research carried out in Scotland. These included geological work on soils, soil survey work, the investigation of soil fertility, and advisory work among farmers.

South Africa: Progress of Twenty-five Years

THE special South Africa supplement of *The Times*, presented with the issue of May 31, deserves mention for its wealth of interest and its authoritative articles. Published to commemorate the silver jubilee of the Union of South Africa, the supplement reviews the progress of the Dominion during the last twenty-five years. Articles on agriculture, mining, migration, education, wild life and native affairs are particularly noteworthy; but other sides of South African life, such as finance, architecture, sport, communications and holiday resorts are not omitted. Altogether, the supplement, which runs to thirty pages and is illustrated with maps and photographs, may be regarded as an important 'volume' on all aspects of South Africa, and one of permanent value.

Malaria in Ceylon

THE seriousness of the epidemic of malaria that has been raging in Ceylon may be realised from the fact that 74,000 deaths are attributed to this disease during the six months, November–April. Up to the end of April, nearly two million rupees were expended in relief, exclusive of sums for medical treatment. The situation has afforded an opportunity to test on a large scale the value of quinine and of synthetic antimalarial drugs, and the report thereon when published should prove of great value.

British Standard Density Hydrometers

THE Hydrometer Sub-Committee of the British Standards Institution has prepared a draft specification for British standard density hydrometers and tables for use with the hydrometers. The draft specification and tables are now being circulated to interested bodies by the Institution for criticism prior to their final publication. The Institution would welcome comments on the proposals from as wide a circle as possible, and a copy of the draft specification and tables will be forwarded to anyone interested on application to the Director, British Standards Institution, 28 Victoria Street, London, S.W.1.

Nutrition Advisory Committee

THE Minister of Health and the Secretary of State for Scotland have appointed a Nutrition Advisory Committee to "inquire into the facts, quantitative and qualitative, in relation to the diet of the people, and to report as to any changes therein which appear desirable in the light of modern advances in the knowledge of nutrition". The members of the Committee are: Lord Luke (chairman), Mrs. Eleanor Barton, Mr. J. N. Beckett, Dr. G. F. Buchan, Prof. E. P. Cathcart, Mr. R. R. Enfield, Dr. J. Alison Glover, Dr. J. M. Hamill, Dr. A. Bradford Hill, Sir F. Gowland Hopkins, Dr. Donald Hunter, Prof. E. Mellanby, Sir John Boyd Orr, Mr. E. C. Ramsbottom, Mr. J. M. Vallance, Mrs. Chalmers Watson, Mr. J. R. Willis, Mr. E. H. T. Wiltshire. The secretaries of the Committee are: Mr. W. J. Peete, of the Ministry of Health, London, S.W.1, to whom all communications on the subject should be addressed; Mr. N. F. McNicoll, of the Department of Health for Scotland;

and Dr H E Magee, of the Ministry of Health (Medical Secretary)

National Baby Week

THE National Baby Week Council, 117 Piccadilly, London, W.1, has issued its report for 1934 The propaganda subject for the year was "The Making of an A 1 Nation", and special propaganda dealt with "The Diet of the Expectant Mother" and "Food and Feeding" National Baby Week is to be held this year on July 1–7, and the special subjects suggested for consideration are "The Welfare of the Pre-School Child" and "Good Nutrition of Mothers and Children" A poster competition is arranged for boys and girls of 'senior schools', and prizes are offered to parents for the best essays on one of two subjects. "What should be done were there an Outbreak of Diphtheria", and "On the Effect of Overcrowding on the Welfare of Mothers and Little Children". The Council will gladly advise and give help on propaganda work, the choice of subjects for lectures, etc, and on other matters relating to infant welfare

South-Eastern Union of Scientific Societies

THE fortieth Annual Congress of the South-Eastern Union of Scientific Societies will be held at Bournemouth on June 26–29, under the presidency of Prof A C. Seward On June 26, Prof Seward will deliver his presidential address entitled "The Herbarium of the Rocks" Prof J Cameron will deliver a public lecture on June 27 at 8, entitled "Egyptology"; and Lieut.-Colonel C D Drew will deliver a public lecture on June 28, at 8, entitled "Recent Excavations at Maiden Castle" The following sectional presidential addresses are announced Archæological Section (Mr T D Kendrick), "Early Christian Art in the British Isles", Botanical Section (Prof H J. Tabor), "Effects of Certain Physical Factors on the Determination of Plant Habitat", Zoological Section (Rev. F. C R Jourdain), "Zoological Progress during the last Half-Century, with special reference to Ornithology", Geological Section (Dr H. D. Thomas), "Some Aspects of Evolution", Regional Survey Section (Dr Vaughan Cornish), "Scenic Amenities in Town and Country" Further information can be obtained from the Honorary General Secretary, Mr. Edward A. Martin, 14 High View Close, Norwood, London, S E.19

Announcements

AT a meeting on April 27, the Leeuwenhoeck Gold Medal of the Royal Academy of Sciences, Amsterdam, was awarded to Prof S. N. Winogradsky, foreign associate of the Academy and also a foreign member of the Royal Society, who is director of the Division of Agricultural Microbiology of the Institut Pasteur, Brie-Comte-Robert, France, for his outstanding contributions to the development of soil microbiology. The medal is awarded decennially to commemorate the discovery of micro-organisms by Antony van Leeuwenhoeck. Previous recipients of the medal have been: C. G. Ehrenberg, Ferd. Cohn, L. Pasteur, M. W. Beijerinck, Sir David Bruce and F. d'Hérelle.

DR. WESLEY BOURNE, of Montreal, has been awarded the first Hickman Medal of the Royal Society of Medicine. Dr Bourne is anæsthetist to the Royal Victoria Hospital, Montreal, and also lecturer in pharmacology in McGill University He is well known to many anæsthetists in Great Britain, both personally and for his researches into the physiology and pharmacology of anæsthesia.

SIR FREDERICK HOBDAY will deliver the Stephen Paget Memorial Lecture on the occasion of the annual general meeting of the Research Defence Society on June 12 at 3, in the London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1, taking as his subject "The Relief of Animal Suffering".

THE Walter Rathbone Bacon Travelling Scholarship of the Smithsonian Institution has been awarded to Dr Richard E Blackwelder, now engaged in entomological work at the U S National Museum, for an intensive study of the staphylinid beetles of the West Indies. Dr Blackwelder will collect these curious little beetles, which are distinguished from other families of beetles by their short wing covers, although nearly all have normally large wings and most of them are good flyers, on twenty-five West Indian Islands, including Cuba, Hispaniola, Puerto Rico and Jamaica. After completing his collections in the West Indies, Dr Blackwelder will study the large collections in the British Museum

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—Three University lecturers and one demonstrator in the University of Cambridge—Mr H. Thirkill, Clare College, Cambridge (June 10). A lecturer in mechanical engineering in the West Hartlepool Technical College—The Secretary for Education, Education Offices, West Hartlepool (June 14). A head of the Science Department, Central Polytechnic, Croydon—The Education Officer, Education Office, Katherine Street, Croydon (June 15) A lecturer in physiology in the University of Bristol—The Registrar (June 19). A lecturer in physics and mathematics in the Northampton Polytechnic, St John Street, London, E C.1—The Principal (June 21) Geologists on the Geological Survey of Great Britain and the Museum of Practical Geology, Exhibition Road, South Kensington, S.W.7 —Director (June 21). A lecturer in physics in the Constantine Technical College—The Director of Education, Education Offices, Middlesborough (June 22). A head of the Chemistry Department in the Rutherford Technical College—The Director of Education, City Education Office, Northumberland Road, Newcastle-upon-Tyne, 2 (June 22). An assistant lecturer in agricultural botany in the South-Eastern Agricultural College, Wye, Kent—The Secretary (June 22) A temporary lecturer in geography in Armstrong College, Newcastle-upon-Tyne—The Registrar (June 25). Two research workers at the research laboratory of the Freshwater Biological Association of the British Empire, Wray Castle, Ambleside, Westmorland—The Naturalist-in-Charge (July 1).

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 962.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Echo Sounding in Fishery Research

THE vessel used for the annual oceanographical investigations in the Lofoten area (the *Johan Hjort*) had a Hughes echo sounding gear (magnetostriction system, frequency 16,000 cycles per second) installed before leaving Bergen last February. The gear worked smoothly all along the coast and besides furnishing a great number of interesting sections, revealed many features hitherto unsuspected; among others, that the clay flooring of deep fjords is invariably about 10 m thick and generally very flat.

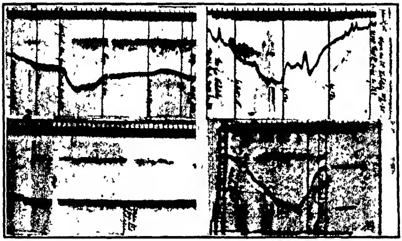

FIG 1 Four 'echo'-records showing spawning cod in midwater at Lofoten. The left-hand diagrams partly with ship stopped. The bottom right-hand record is somewhat disfigured by oscillations set up by excessive shaking of ship's motor, but it shows also a second echo from the bottom, reflected from the surface. Marks on top of each diagram are produced every minute and are 6·7 mm apart.

Marks referable to fish were seen on the record only after the arrival at that portion of the Lofoten fishing area where the most prolific fishing has been going on during recent years—at Høla—a bight of the West Fjord of very restricted dimensions, say, 10 miles by 4 miles. At this place fish were indicated continuously along straight courses of 2 nautical miles and more. The nature of the indications may be seen from Fig. 1, which is a photographic reproduction of four separate records, partly obtained while the ship was stationary among the hand-line boats, which got the fish exactly at the depth indicated.

It is interesting to note that this spawning concentration of cod has apparently no relation to the bottom. This was well known before, but no one could have imagined the fish to be limited to such a sharply defined layer of only 10–12 metres in thickness, extending widely above deep water and shallow, always at the same distance from the water surface. This distance was 72 metres at the first encounter with the spawning shoals (March 11) and 50 metres at the conclusion of this investigation on April 5. Concurrently, the temperature in the 'fish' water-layer had decreased from 6·5°–6·0° to about 3·0° C. In some instances a perceptibly lower oxygen and hydrogen ion concentration was observed in this water-layer than in the layers immediately above and below.

Although two zigzag trips were made across the entire bank area of the West Fjord, strong marks such as those shown in the records reproduced were only obtained at the locality referred to above; in other places only small and widely separated dots. Still a certain amount of fishing, if not very successful, was going on everywhere. A true estimate of the quantity of fish represented by marks of different types can, however, be gained only by further study in connexion with the use of suitable fishing implements.

OSCAR SUND.

Johan Hjort,
Kabelvåg, Lofoten.
April 6.

Absorbing Layer of the Ionosphere at Low Height

THE ionosphere is now generally regarded as divided into two main regions of intense ionisation. The upper (*F* or Appleton) region commences at a height of about 250 km., while the lower (*E* or Kennelly-Heaviside) region begins at a height of about 90 km. Besides these two main regions, the existence of a so-called *D* or absorbing layer has been suggested from time to time[1]. The presence of such a layer has not, however, until now been experimentally demonstrated, and it has rather been the tendency in recent years to discredit its existence. Recently we have, however, in the course of our ionospheric studies at Calcutta been able to detect echoes of radio waves returned from a virtual height of about 55 km. by the well-known pulse method. The echoes from the *E* layer were at the same time observed to be returned from a virtual height of 119 km. The present communication gives a preliminary account of the observations we have made in connexion with the existence of a low-lying absorbing layer.

The appearance of echoes from the *D* layer is closely connected with the weakening of echoes from the *E* layer which is observed with the progress of the day[2]. This absorption may be due either to a decrease in the gradient and lowering of the height of the lower boundary of the *E* layer, or to the formation of a distinct absorbing layer at a much lower

level. Against the first hypothesis, both observations and calculations show that the lower boundary of the E layer must be extremely sharp[1] From such a boundary all frequencies below the critical penetration frequency will be copiously reflected, while all those above will penetrate the boundary Observations made by us, however, show that during daytime there is a frequency band above and below the limits of which no reflection is obtained from the E layer The limits of the frequency band vary with the hour of the day Fig 1 depicts typical limits on a summer day at Calcutta

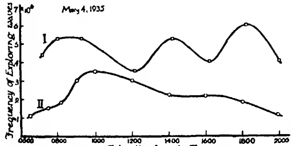

FIG 1 Curve I gives the penetration frequencies of the E layer for various hours of the day Curve II gives the frequencies for which echoes from the E layer first appear from the side of long waves The vertical distance between the two curves for any hour of the day gives the range of frequency for which echoes are obtained from the E layer only

The hypothesis of a diffuse D layer at low height, where collision frequency is very great, offers an easy explanation of these phenomena This layer will absorb long waves strongly, preventing their reflection due to the diffuse boundary, and will only allow waves of lengths below a certain limit to penetrate it These latter waves will either be reflected from or will penetrate the E layer In short, the E layer with its sharp boundary will reflect all frequencies below a certain limit and the D layer with its diffuse boundary absorb all frequencies below another lower limit The sharp boundary of the E layer cannot cause the disappearance of frequencies lower than the critical penetration frequency as shown in Fig. 1 The hypothesis of a diffuse E layer boundary causing absorption is untenable because the virtual height of the E layer as measured by us for a number of frequencies in the frequency band of Fig. 1 has been found to be practically constant.

On very rare occasions when the lower boundary of the D layer becomes extremely sharp, it is able to reflect waves. Such were the occasions on April 2, 3 and 5 between the hours 15 00 and 17 00, when we were able to detect the echoes as reported in the beginning of the note.

There are other arguments in favour of the existence of the D region Without the intervention of such a region, the virtual height of the E layer ought to rise gradually with the setting of the sun Observations show, however, that the height has a tendency to decrease with the close of the day This is easily explained as due to the disappearance of the D layer, which by its presence during the day increases the virtual path of the wave Again, Fig 1 shows that Curve I, which is a graph of the penetration frequencies of the E layer, has pronounced hourly variations. This feature of the curve is present almost every day during this part of the year. Curve II, which is a graph of the frequencies for which echoes begin to appear from the E layer, has no such pronounced hourly variations, but gradually rises and falls with the progress of the day. There being scarcely any correlation between the two curves, it follows that the agency responsible for Curve I must be different from that for Curve II This other agency, according to our hypothesis, is the absorbing layer at a virtual height of 55 km

It is noteworthy that the region where the absorbing layer has been detected by us, is also, according to many authorities, the region of the ozonosphere[4] It is not unlikely that the ionisation in this region is connected with the formation of ozone, as suggested by Chapman[5]

Propagation of Radio Waves over a Plane Earth

THE purpose of this letter is to point out an error in sign in Prof A. Sommerfeld's original paper (1909) on the attenuation of radio waves[1] This error in sign has recently been reflected in Bruno Rolf's graphs[2] of the Sommerfeld formula, predicting dips to zero in the field intensity at finite distances from a radio transmitter and other anomalous phenomena. This error in sign has been corrected in Prof Sommerfeld's 1926 papers[3] and also does not occur in the derivation by B van der Pol and K F Niessen[4]. In this latter paper an exact expression is given for the potential of a vertical infinitesimal dipole (equation 21) After expanding this expression, I found that most of the terms are negligibly small at moderately low frequencies for distances from the source greater than a wave-length, giving for the potential function of a vertical dipole over a plane earth:

$$\Pi (r, 0) = \frac{e^{ik_1 r}}{r}\left[1 - 2\sqrt{p}\, e^{-p}\int_{i\infty}^{\sqrt{p}} e^{w^2} dw\right]$$

$$\text{where } p = ik_1 r\left[1 - \left\{1 + \left(\frac{k_1}{k_2}\right)^2\right\}^{-1/2}\right] \equiv p_0 e^{ib} \quad (1)$$

and $k_1 = \dfrac{2\pi}{\lambda}$, and $k_2^2 = k_1^2(\epsilon + i2c\lambda\sigma)$,

where ϵ is the dielectric constant of the ground referred to air as unity, σ is the conductivity of the ground in electromagnetic units, c is the velocity of light in cm. per sec., λ is the wave-length in cm. and r is the distance in cm.

In the above equation, p is the 'numerical distance' as defined by van der Pol and Niessen and is slightly different for high-frequencies from the 'numerical distance' used by Sommerfeld; this difference makes the above formula accurate for large values of the

parameter b and free from the errors which Rolf[5] made by using the Sommerfeld 'numerical distance'

Rolf used equation (1) with the lower sign reversed on the integral for computing the field intensity from a distant radio transmitter Correcting this error in sign, I have found that the following empirical formula for the field intensity may be determined from equation (1)

$$F = \frac{c}{r}\sqrt{P}\left[f(p_0) - \sin b\sqrt{\frac{p_0}{2}}\,e^{-\frac{5}{8}p_0}\right] \quad . . . . . (2)$$

This formula gives the field intensity, F, in microvolts per metre when the radiated power from the transmitter is P kilowatts and is applicable for $b < 30°$, that is, for frequencies less than about 10,000 kc/s for transmission over ground of average conductivity about 10^{-13} E M U. The quantity in the square brackets is the 'attenuation factor' and reduces to $f(p_0)$ in the case $\left|k_0^2\right| >> k_1^2$. This was the case discussed by Sommerfeld, and values for $f(p_0)$ are given by Rolf in his first paper—van der Pol[6] also gives the following empirical formula for $f(p_0)$:

$$f(p_0) = \frac{2 + 0.3p_0}{2 + p_0 + 0.6p_0^2} \quad . . . . (3)$$

Formula (2) is limited in this application to a plane earth, the actual ground wave field intensity being influenced by the curvature of the earth at the greater distances, this effect being the predominating influence at sufficiently low frequencies

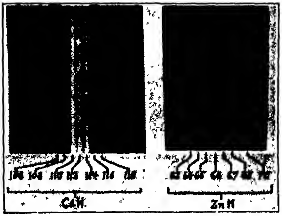
Band Spectroscopic Observations of the Isotopes of Zinc and Cadmium

ACCORDING to earlier mass-spectroscopic investigations by Aston[1], cadmium has the following isotopes arranged in order of their abundances: 114, 112, 110, 111, 113, 116. Later, two additional isotopes, 108 and 118, were observed by one of us[2], as a result of an investigation of the band spectrum of cadmium hydride.

Recently, Aston[3] has reported the discovery of three new cadmium isotopes, 106, 108, 115, but no evidence of the existence of Cd^{118} was obtained. As Cd^{106} appeared to be more intense than Cd^{108}, and the former isotope had not been mentioned by Svensson, Aston concludes that these results are not reliable; in particular, that the existence of Cd^{118} must be considered as rather dubious.

Our spectrograms, on which the above mentioned observations were based, did really give indications of lines corresponding to Cd^{106}, but were not published because of their spurious appearance as compared to the lines of $Cd^{108,118}$ which were present in some thousands of groups in the spectrum. As may be seen from Fig. 1 (*a*) representing the group at λ 4728 A and corresponding to R_2 (18½) in ($v'=0$; $v''=3$) of the $^2\Sigma \rightarrow {}^2\Sigma$ transition, Cd^{106} is present, although having decidedly less intensity than $Cd^{108,118}$. This intensity relation seems to hold throughout the observed spectrum The existence of odd isotopes in cadmium could not be verified[2] on account of insufficient separation of the even components in a group.

The isotopes of zinc have also been the subject of several investigations, contradictory results having been obtained Thus according to Aston[4], the following isotopes are present 64, 65, 66, 67, 68, 69, 70 Bainbridge[5], however, was unable to observe $Zn^{65,69}$. From an unpublished investigation on the band spectrum of zinc hydride, one of us (G. S) observed the following isotopes 64, 66, 68, 67, 65, 63, 70, their abundances being in the order in which the numbers are given Thus agreement is found with the results of Aston regarding Zn^{65} (not observed by Bainbridge) and vice versa regarding Zn^{69} Our new isotope Zn^{63} is clearly visible in Fig 1 (*b*),



(*a*) (*b*)

FIG 1

representing the group at λ 4035 0 A and corresponding to R_1 (33½) in ($v'=0$, $v''=0$) of the $^2\Pi_{3/2} \rightarrow {}^2\Sigma$ transition The line corresponding to Zn^{63} is far more intense than that of Zn^{70}, which is too faint to appear on the reproduction, although clearly visible on the original plates

Our statements regarding the isotopes of zinc and cadmium are based on observations of extensive regions in the spectra of their hydrides. Some thousands of line groups have been measured in each spectrum, the isotope separations being in perfect agreement with the theory of isotope effects in band spectra. We would suggest, therefore, that the disagreement between band spectroscopic and mass-spectroscopic observations regarding the existence of isotopes does not indicate the unreliability of the former method but must be explained in some other way.

Raman Spectrum of Deuterobenzene

WE have photographed the Raman spectra of the various deuterobenzenes. In order to obtain the isotopic shifts of the Raman frequencies with a fair accuracy, the spectra were investigated with high dispersion, which necessitates a rather large volume of the substance, the Raman tube employed contained 18 c c For the preparation of deuterobenzene we have investigated various possible exchange reactions and have finally chosen the Friedel Craft reaction

$$C_6H_6 + 6DCl \underset{AlCl_3}{\rightleftarrows} C_6D_6 + 6HCl.$$

This process has the advantage of high reaction velocity, and further, our experiments indicate an appreciable shift of the equilibrium towards the deuterobenzene Details concerning this reaction as well as the common physical properties of the deuterobenzene will appear elsewhere Of course this method produces a mixture of the various deuterosubstituted benzenes in proportions very nearly corresponding to the probability distribution By photographing the spectra of deuterobenzenes with various contents of deuterium, it is consequently possible to identify the Raman lines belonging to each deuterobenzene

We have measured the complete Raman spectra of the molecules C_6H_5D, C_6D_5H and C_6D_6 All the Raman frequencies of benzene are found to be lowered by introduction of deuterium in the molecule

FIG 1

Fig 1 is an enlargement of a part of two Raman plates and shows the isotopic shift of the strongest line of the spectrum, namely, the frequency corresponding to the symmetrical ring vibration The plates show distinctly greater isotopic shift between C_6H_6 and C_6H_5D than between C_6D_5H and C_6D_6, owing to the comparatively greater alteration in mass in the first case. The Raman frequencies are respectively 992·6, 981 5, 952 4 and 946 6 cm^{-1}.

The Raman frequencies of C_6D_6, together with those of C_6H_6, are as follows:

Raman Frequencies (cm^{-1})

C_6H_6 606 4, 849·7, 992·6, 1175 6, 1585 9, 1604·2, 3048 3, 3061·5

C_6D_6 581·6, 844·7, 946·6. 869·8, 1555 4, 1569 0, 2266·8, 2292 0.

It is interesting to note the great shift of the 1175·6 line in benzene (to 869·8 cm.$^{-1}$ in C_6D_6), which shows that this frequency, as well as the 3048·3 and the 3061·5 frequencies, belongs to a pronounced hydrogen vibration.

The spectra of C_6H_5D and C_6D_5H are much more complicated owing to the split up of the degeneracy of certain vibrations in the symmetrical molecules C_6H_6 and C_6D_6, and are of great interest for the identification of these. A detailed report of the investigation and a discussion of the results will appear shortly elsewhere.

Spontaneous Emission of Neutrons by Radio-elements

I CURIE, Joliot and Preiswerk[1] have shown that by bombarding silicon and phosphorus by neutrons there are produced radio-elements which spontaneously emit neutrons, in addition to electrons (Fermi effect), positrons and γ-rays Thus an entirely new type of radioactivity has been discovered by them

The mechanism of the spontaneous ejection of neutrons is not fully understood. At any rate, it may be supposed that this process is a secondary one, as the experiments on the Fermi effect have shown clearly enough that the potential energy of the neutron in the nuclear field is negative (the barrier is absent), and hence the neutron, having received somehow or other some positive energy, must leave the nucleus immediately or pass into a state of negative energy, exciting another particle or emitting γ-quanta

In their communication, I Curie, Joliot and Preiswerk explain the emission of the neutrons by the following processes

$$(1)\ {}_{13}Al^{28} \to {}_{13}Al^{27} + {}_0n^1 \text{ and } (2)\ {}_{14}Si^{31} \to {}_{14}Si^{30} + {}_0n^1$$

Such an interpretation (primary process) cannot be admitted according to the considerations mentioned above, moreover, it would seem impossible energetically, although we cannot assert this definitely because the accurate values of the masses of all the components of reactions 1 and 2 are not known

I have attempted to find the energy distribution of the spontaneously ejected neutrons or at least to estimate its upper limit. For the detection of the neutrons I used a photographic plate with a thick layer of emulsion (50 μ) specially prepared for the registration of H-particles. At a distance of 0·2–0·4 mm of the plate, there was placed a paraffin film and thus were registered the protons ejected by the neutrons from paraffin (Fig. 1) Radioactive isotopes were being produced in red phosphorus by neutron bombardment. A glass tube containing radon (about 250 mc.) and some powdered beryllium served as the source of neutrons. Every 10 minutes the bombarded phosphorus was brought into the immediate neighbourhood of the photographic plate for a period of

FIG 1 Stereoscopic photomicrographs of the track of a recoil proton in photographic emulsion Length of the track is 72μ (~2 6 × 10⁶ e v)

10 minutes. The total time of the experiment was about 12 hours

As a result there was revealed the presence of 15 recoil protons the energy of which is represented graphically in Fig 2 (protons of energy 10^6 e v and

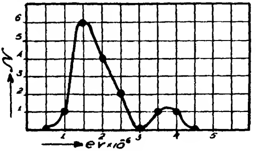

FIG 2

above are detected by this method) The greatest energy of the observed protons was $\sim 4 \times 10^6$ e v Thus the upper energy limit of the neutrons spontaneously emitted by some disintegration products of phosphorus is at any rate $\geqslant 4 \times 10^6$ e v

In conclusion, I wish to express my best thanks to Mr A Jdanoff for his kind help

The Fundamental Paradox of the Quantum Theory

ACCORDING to the general principles of the quantum theory, physical variables $a, b, c,$ are represented by symmetric linear operators $A, B, C,$. in Hilbertian space; and the representation satisfies the following conditions:

$$a^2 \rightarrow A^2, \lambda a \rightarrow \lambda A, \text{ (}\lambda\text{ being an ordinary number)}$$
$$a + b \rightarrow A + B$$

Since $ab = \frac{1}{4}(a+b)^2 - \frac{1}{4}(a-b)^2$, it follows that $ab \rightarrow \frac{1}{2}(AB + BA)$

Similarly,

$$ab.c \rightarrow \tfrac{1}{4}(AB + BA)C + \tfrac{1}{4}C(AB + BA),$$
$$ca.b \rightarrow \tfrac{1}{4}(CA + AC)B + \tfrac{1}{4}B(CA + AC),$$
$$bc.a \rightarrow \tfrac{1}{4}(BC + CB)A + \tfrac{1}{4}A(BC + CB)$$

The general principles will therefore lead to a contradiction unless these three operational representations of abc are all equal. This implies that

$$A(BC - CB) = (BC - CB)A,$$

with two similar equations. Hence the commutator $(BC - CB)$ of any two operators representing physical variables must commute with every operator representing a physical variable Therefore, by Schur's lemma, $(BC - CB)$ must be a numerical multiple, $\lambda_{BC}I$, of the unit matrix I, in any irreducible matrix representation.

Now, if $ab \rightarrow X$,

$$\lambda_{XC}I = XC - CX = \tfrac{1}{2}(AB + BA)C - \tfrac{1}{2}C(AB + BA)$$
$$= \lambda_{BC}A + \lambda_{AC}B.$$

Hence $\lambda_{XC} = \lambda_{BC} = \lambda_{AC} = 0$, and all the commutators vanish Therefore any *two operators which represent physical variables must commute*. This result can only be reconciled with the accepted exchange relations by taking the numerical value of Planck's constant to be zero This destroys the whole structure of the modern form of the quantum theory

Chromosomes of the Tulip in Mitosis

IN a recent study of the development of the male gamete in the style of *Lilium regale*, O'Mara[1] states that no equatorial plate is formed, but that at metaphase the chromosomes lie scattered in the pollen tube Welsford[2], on the other hand, illustrates in *L Martagon* (her Fig 16) the complement normally arranged on a plate

FIG 1 Pollen tube division of *Tulipa Greigi* from an artificial culture of pollen, 24 hours after sowing on 14 per cent cane sugar agar

I have obtained pollen tube divisions in *Tulipa Greigi* in artificial culture, using McClintock's acetocarmine method (Fig 1) The metaphases are perfectly normal, with a definite equatorial plate, and the anaphases resemble those of the pollen grain except that the poles of the spindle are considerably farther apart

In my experiment, the artificial medium may permit of the formation of wider pollen tubes than in *L. regale* It is unlikely, however, that an irregular metaphase would give the regular anaphase distribution required to produce the viable gametes of this species More probably, therefore, a true metaphase plate is formed, though the stage may be rapid and not easy to find

The technique which I have used further reveals the structure of the mitotic chromosomes in a way not otherwise possible The method can only be applied to the study of mitosis in pollen grains and pollen tubes, but the thick wall of the pollen grain apparently modifies the action of the fixative

By this fixation the chromosomes show striations which are independent in each chromatid, and are presumably caused by a slight separation of the coils of the spiral chromosome thread It is not possible to determine the direction of coiling, but there is evidently no change of direction, since there are no breaks in the spacing of the coils

The following measurements show the sizes of the structures involved :

Length of arm of chromosome	17 0 μ
No of spirals	33
Diameter of chromatid	1 2 μ
Calculated diameter of chromosome thread $= \frac{17\ 0}{33}\ \mu =$	0 52 μ.

Evidently the structures shown by this technique are comparable with those illustrated by Vejdovsky at metaphase in *Ascaris*[3] and by Darlington at telophase in *Fritillaria*[4] The whole volume of each chromatid is taken up by a chromosome thread 0 5 μ in diameter compactly coiled to give a rod approximately twice its diameter.

Those findings are therefore incompatible with those of Sharp[5] and other workers of the chromonema-matrix school

Use of Reflected Light in the Examination of Fossils

SEVERAL very ingenious methods for facilitating the microscopic examination of the structure of plant fossils have been recently described and illustrated in NATURE No mention, so far as I have noted, has been made of that by which the smoothed surface of a fossiliferous rock is examined by reflected light, as may be done with the 'ultropak' microscope. In this instrument, as many will know, the light is introduced laterally into the body of the microscope, reflected downwards by an annular mirror and brought to a focus by an annular condenser in front of the objective

FIG. 1 Photomicrographs of coal Left hand Megaspore or megasporangium on smoothed surface of Wigan coal parallel to bedding × 32 5 diam. Right hand. Transverse section of stem seen on smoothed surface of Westphalian coal. × 75 diam.

The accompanying photomicrographs (Fig 1) were made by this way, from ordinary coal. The method is equally applicable to siliceous and calcareous fossils, but the results, obtained with a few minutes' preparation from coal fossils, usually so hard to deal with, seemed to me most surprising Higher magnifications giving 300–400 diameters with oil-immersion lenses are also feasible.

Effect of Orange Juice on the Growth of *Laminaria* Gametophytes

SOME interesting nutritional effects have been observed in cultures of gametophytic and young sporophytic plants of *Laminaria saccharina* Lamour by the addition of low concentrations of orange and other fruit juices After the *Laminaria* spores had been introduced into petri dishes containing 25 c c of filtered sea-water, orange juice was added in the proportion of 1 c c of a 1 per cent extract to each dish Control cultures were kept under identical conditions of light and temperature

Normally, on germination the contents of the spore pass through the germ-tube into the enlarged distal end, giving the early stage of the 'effective plant' In cultures containing sea-water alone, the young gametophytes remained in this condition for a period varying from a few days to some weeks In cultures to which orange juice has been added, this temporary resting stage is greatly reduced

Previous investigators have shown that sexual organs may be produced either in the one-celled condition or from any cell of a filamentous gametophyte. The filamentous form of gametophyte is produced either when temperature and light intensity are high, or when phosphate is present in excess of nitrate[1]. The presence of orange juice stimulates the formation of filamentous gametophytes and also the production of sexual organs (Fig. 1, *a* and *b*)

Algologists have frequently observed that, in culture, the plants floating in the surface film of the medium show reactions different from those of the submerged plants. It is, perhaps, not without significance that in cultures to which orange juice has been added, the greatest growth is usually observed in the submerged germlings.

Analyses of sea-water made at different times of the year show a marked diminution in the amounts of dissolved nitrate and phosphate present during the spring and early summer. Experiments carried out with cultures supplied with 1 c.c. of 0·01 molar potassium nitrate, potassium iodide and potassium phosphate in addition to the fruit juices show an acceleration of growth and development which is equally marked (Fig. 1, *c* and *d*). Vigorous young sporophytes have been produced in these treated cultures.

Further experiments are in progress to determine the effect of different concentrations of various fruit

juices, of the addition of ascorbic acid (vitamin C) contained in these juices and of other growth-

Birds and Butterflies

IN reference to the palatability of butterflies, it may be interesting to record that the Australian grey butcher bird, *Cracticus torquatus*, does not object to eating butterflies A tame bird which I have had under observation, though pinioned, manages to catch skippers of the species *Anasynta sphenosena*, when these are flying round flowers within reach. I have also seen the bird catch the same species in the early morning before the butterflies have become active. The butterflies are seized with the bill, beaten once or twice against the ground or against some hard object, and then swallowed whole. The fact that on one occasion the bird caught and ate a skipper soon after it had been fed with its customary ration of raw meat indicates that it was not hunger that persuaded the bird to take the butterfly.

The same bird also eats the introduced sand hill snail, *Helix pisana*. The victim may be either crushed with the powerful bill or beaten against the ground, but an anvil stone such as used by the English thrush is not utilised. Much of the shell is swallowed, to be disgorged later in the pellet Examination of these pellets also shows that ants are freely eaten.

Chemistry of Œstrogenic Substances

IN view of the results published by E. Friedmann in NATURE of April 20, we decided to investigate the effect upon ovariectomised rats of the two compounds specifically mentioned by him as œstrogenic, namely, sodium benzylidenepyruvate and sodium furylidenepyruvate These were prepared and purified exactly as described by Friedmann[1] They were dissolved in water, the strength being 100 mgm in 3 c c, and administered in 6 doses of 0·5 c c, each compound being injected into 5 rats The technique employed was that described in the paper by Allan, Dickens and Dodds[2]

A similar experiment was performed using the two free acids (100 mgm dissolved in 3 c c of sesame oil and divided into 6 doses of 0 5 c c), five rats being used for each of the two acids

Examination of the vaginal smears showed that there was no œstrogenic activity either with aqueous solutions of the sodium salts or with solutions of the free acids in oil when injected in amounts of 100 mgm per rat

Research and the Library

THE suggestions of Drs Berry and Bonser on this subject[1] will be of interest to all who are appalled by the unabating flood of scientific literature

There are two points to which I would direct attention First they state: "It has long been the practice of chemical journals to accept only new matter, and this cut down to the briefest account. This principle can be adopted with advantage in other scientific subjects" Chemistry is an exact science, and what may be an excellent method of presenting its results may not be best for a biological subject. In zoology a statement of results or observations is valueless unless it is followed by a discussion in which the new results are correctly orientated in relation to previously known facts Facts by themselves mean nothing, only when they are seriated into a hypothesis do they take on any value.

The adoption by certain zoological journals of the criteria of chemical journals has had the unfortunate effect of restricting discussion and has produced a multitude of isolated pieces of information Thus I cannot agree with Drs Berry and Bonser when they suggest that accounts of the debates of certain societies should not be published, for by ordered discussion alone can science be advanced. The mere accumulation of details and isolated facts is not scientific advancement

A scientific paper should consist of three parts: an introduction explaining why and how the investigation was undertaken; the observations; and finally their interpretation. If all papers were so composed and there was adequate discussion of all points raised, not only would the publication of

incomplete work be checked, but also the number of papers published would be halved, for the discussion would show the writer that half the facts he would normally record are insignificant details having no bearing on his general argument

Secondly, the suggestion of Drs Berry and Bonsor that there is a tendency for the young research worker to be judged upon the number of his papers rather than on their quality, gives rise to many thoughts which cannot be touched on here But it does prompt the question as to how much research is done with the idea of the advancement of some branch of science and how much for added professional qualification To-day, even for minor posts, candidates are expected to have research qualifications, and quantity rather than quality will continue to count unless those responsible for making such appointments are prepared either to seek such expert advice on the publications of the candidates as they would for a senior post, or to pay less attention to this aspect of the qualifications

Whether the apparent respect paid to all forms of research is genuine is another matter, for the reward for the most brilliant research would appear to be, not the means and leisure to continue it, but a post involving such administrative or teaching duties as to make further research impossible

Plasticity of Rock Salt and the Taylor and Becker-Orowan Theories of Crystalline Plasticity

In Prof Taylor's theory of crystalline plasticity[1] the process of slip is conceived as the result of the propagation through the lattice of a definite type of deviations from the 'ideal' structure, so called dislocations[2] The path of a single dislocation in general is limited by the faults or flaws in the crystal and it is assumed that the number N of propagated dislocations increases during the course of the process Every dislocation is the centre of a field of stress, the various dislocations influence each other's motions and it is shown that centres will escape from each other only if the applied exterior stress exceeds a certain value, increasing with N Hence the stress necessary for further deformation increases with the deformation already attained ('shear hardening') It is suggested by Taylor that the dislocations might arise as a consequence of thermal agitation, but no explicit explanation is given of the progressive increase of N

Now, in the Becker-Orowan theory, gliding is conceived as starting from 'jumps', originating at favourably situated flaws under the combined influence of the exterior stress τ (enhanced by the so-called stress-concentration effect), and of thermal agitation (producing local stress fluctuations[3]) This conception leads to a relation between τ and the rate of flow, from which also the minimum value τ_f necessary to produce an observable rate of shear at a given temperature can be estimated. It is put forward by Orowan (l c, p. 639) that these local jumps initiate dislocations of similar type as considered in Taylor's theory If such dislocations, once formed, move only over a finite distance and are then arrested at 'opaque' flaws, it would seem to us that they will give rise to an 'interior' field (similar to that introduced by Taylor, though now essentially connected with the lattice distortions at the places where dislocations have been arrested), of a stress τ_i increasing with the number of dislocations formed In those regions where jumps have occurred the interior field in the main will counteract the exterior field, and thus we must expect that the production of new dislocations will take place at a continuously decreasing rate When τ_i has increased so much that $\tau - \tau_i$ approaches to the value τ_f, the deformation practically comes to a stop, as then new dislocations are formed so slowly that their only effect will be a very small creep. Reasoning along these lines it seems possible to arrive at a combination of the two theories, which explains both the shear hardening effect and the dependence of the rate of flow upon exterior stress and temperature[4].

The picture obtained suggests that the plastic properties of a crystal will be enhanced if it is possible to keep down the interior field τ_i It seems worth while to consider from this point of view the remarkable fact, observed by Smekal[5], that on stretching a piece of rock salt the actual gliding among several equivalent sets of glide planes chooses that set, for which the direction of gliding occupies the shortest way in the piece If it is assumed that a certain proportion of the dislocations which arrive at the surface layer of the crystal are able to 'escape', so that they do not contribute to the interior field, the interior field for a given total shear will be the smaller when the number of dislocations that can arrive at the surface is greatest, which will be the case for the shortest glide path

To some extent, similar reasoning may perhaps help to understand the much discussed influence of water on the plasticity of rock salt If the water has a 'healing' effect on the surface layers, those dislocations which were arrested by flaws in these layers can escape, and thus a decrease of τ_i will be effected This means that a definite exterior stress can give rise to the birth of a larger number of dislocations and thus to a larger shear

The above suggested 'explanation' of the Joffé effect as a 'surface effect' apparently fits in with the conceptions of W Ewald and M Polanyi[6] If it were assumed, as has been proposed by Smekal and co-workers[7], that the water penetrates into the crystal, an increase in plasticity could be effected also if the 'opacity' of *internal* flaws for the passage of dislocations were diminished, thus increasing their mean 'free path' L This second explanation would be similar in nature to that accepted by Taylor for the influence of temperature on the degree of plasticity

Electrical Properties of Wires of High Permeability

IN the course of an investigation into the properties of wires of the high permeability nickel-iron alloys of the mumetal group, we have found some interesting results when such wires are made to carry alternating current at audio-frequencies

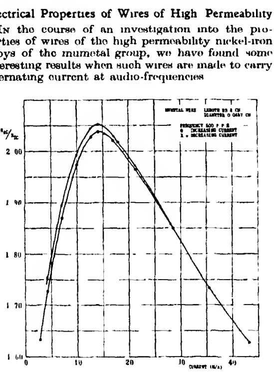

FIG 1

There is a pronounced 'skin effect' even in fine wires, owing to their abnormal permeability, at frequencies as low as 50 periods per second, at present the limit of our experiments In addition, the application to the wire of a small external axial magnetic field of the order of that of the earth, causes a strikingly large change in its impedance

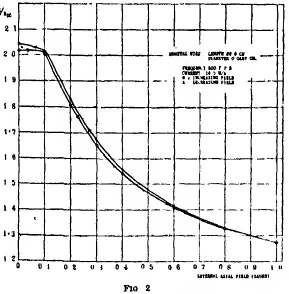

FIG 2

When the external field is constant it is found that the effective (A C.) resistance varies with the value of the alternating current in the wire, and for any frequency always comes to a maximum for some particular current which for convenience we may call the optimum current for the wire at that frequency As an example, in a mumetal wire, 23 5 cm long and 0 0457 cm in diameter (dimension ratio 510) suitably heat-treated, the variation of effective resistance with current at a frequency of 500 p p s is shown in Fig 1 It will be observed that there is a slight but appreciable hysteresis effect

When the current in the wire is kept constant at the 'optimum' value of 14 5 milli-amperes, and the external axial magnetic field is varied, the variation of effective resistance is shown in Fig 2 A small hysteresis effect is again noticeable For currents either larger or smaller than the optimum, the corresponding field-resistance curves lie below that shown in Fig 2, and their maximum gradients are smaller

Changes in reactance as current or external field is varied also occur, but are in general smaller than those of effective resistance

By using a wire with a larger dimension ratio, the changes of effective resistance in fields less than 0 2 gauss may be considerably increased As an example, a wire of length 15 25 cm and diameter 0 0179 cm (dimension ratio 850) carrying A C at 500 p p s, and lying horizontally at right angles to the magnetic meridian, suffered a decrease in effective resistance of about 18 per cent when turned through 90° in the horizontal plane This, combined with a power factor in the wire of 0 97, means an impedance change of about 17 per cent, if the small reactance change be ignored

A detailed account of these experiments will shortly be published elsewhere

Thermal Oxidation of Formaldehyde

CARRUTHERS and Norrish[1] have observed that the polymerisation of formaldehyde is induced by formic acid, produced in the photochemical oxidation An induced polymerisation apparently accompanied by an induced decomposition occurs in the thermal oxidation, at temperatures as high as 317° This reaction possesses many features of interest from the point of view of the theory of chain reactions Direct analysis has shown that the rate changes with time as predicted by the theory for chains with degenerate branching[2] Furthermore, in a series of mixtures, the initial rate depends on the third power of the formaldehyde concentration and is independent of oxygen concentration down to pressures of a few millimetres In a single experiment, however, these conditions do not hold good, and with a sufficiently high initial velocity, good unimolecular constants can be obtained over a large range.

It is not easy to explain this effect by a catalysis due to the final products, but Semenoff[3] has shown that such behaviour is to be expected in reactions where there is a mutual interaction of chains Perhaps the most unusual feature occurs in the experiments with vessels of different diameter No considerable

difference could be observed in the amounts of CO and CO_2 produced in a given time in a series of vessels ranging from a 161 c c bulb down to a 1 mm capillary tube, despite the fact that polymerisation in the narrow tubes was sufficiently rapid to cause a considerable diminution in pressure instead of the usual increase due to the reaction $2HCHO + O_2 \rightarrow 2CO + 2H_2O$ However, when a tube packed with powdered Pyrex glass was substituted, the course of the reaction changed and the gaseous product consisted almost entirely of CO_2 Packing has a similar effect on the course of the oxidation of acetylene[4], but the rate of production of CO falls off rapidly when the diameter is decreased below 6 mm[5] This critical region of diameters, if it exists, must lie well below 1 mm in the case of formaldehyde, yet the other characteristics of the reaction are certainly indicative of a chain mechanism

Points from Foregoing Letters

THE addition of echo sounding gear to the *Johan Hjort* enabled that vessel to reveal unsuspected features of the flooring of deep fjords, and to locate swarms of spawning cod in the neighbourhood of Lofoten. These, writes Oscar Sund, were mainly in a layer of 10–12 metres thick at a constant depth where a somewhat lower oxygen concentration and greater acidity could also be detected

Prof S K Mitra and P Syam report the detection of radio waves returned from a height of only 55 km Although these have only been detected occasionally, the authors believe that the ionised layers to which the effect is due exist usually in a diffused form which strongly absorbs longer waves, and affects the virtual height of the Kennelly Heaviside region above it

An error in sign (later corrected) in Prof Sommerfeld's original paper on the attenuation of radio waves had led to the prediction of a zero field intensity at finite distances from a radio transmitter K A Norton points this out and gives a new empirical formula for the field intensity, applicable, however, only to a plane earth

The existence of a cadmium isotope of mass 118 has been deduced from the band spectrum of the light emitted by cadmium hydrides, but has not been identified by means of the mass-spectrograph. Gösta Stenvinkel and Erik Svensson claim that the evidence from the spectrum of the light emitted by the hydrides is conclusive, as is shown by its ability to detect the existence of other known isotopes of cadmium and zinc, for which the mass-spectroscopic evidence is conflicting

The introduction of heavy hydrogen in place of the ordinary variety in organic compounds changes the Raman spectrum of the light scattered by those compounds From the shift observed in certain spectrum lines of benzene, A Klit and Dr A Langseth associate some of the spectrum lines with the structural characters of the benzene molecules

The neutrons spontaneously emitted by phosphorus previously bombarded with other neutrons (from a radon-beryllium source) may possess more than four million volts energy In I. Gurevich's view, neutron emission is a secondary process, and not a primary process as suggested by Curie, Joliot and Preiswerk.

From the general principles of the quantum theory, Prof. G. Temple deduces the paradox that any two 'operators' which represent physical variables must commute. This would make Planck's constant zero.

The arrangement of the chromosomes during cell division in the pollen tube of the tulip is found by Miss M B Upcott to be normal, unlike the behaviour reported by O'Mara in the case of the *Lilium regale*. From measurements of the structures involved, Miss Upcott concludes that the whole volume of the chromatid is taken by a chromosome thread compactly coiled

Prof H H Dixon submits photomicrographs of coal by reflected light, taken with the 'ultropak' type of microscope in which the light is introduced laterally into the body of the microscope, and reflected downwards by an annular mirror

The addition of orange juice to sea-water quickens the development of the sea-weed, *Laminaria saccharina* (sugar wrack) in its early stages, the greatest growth being observed in submerged germlings P W Carter gives diagrams showing this effect, and also that of the addition of potassium salts.

As a contribution to the discussion on the palatability of butterflies, L Glauert writes that he has observed the Australian butcher-bird catching specimens of the species *Anasynta sphenosena* even when not driven by hunger.

Experiments by Profs J W Cook and E C Dodds fail to confirm the recent observations of E. Friedmann on the œstrogenic activity of sodium benzylidenepyruvate and sodium furylidenepyruvate upon rats

In order to explain the progressive increase in the shearing force needed, and the irreversible deformation with temperature in the case of experiments with rock-salt, Dr. W. G. Burgers and J. M. Burgers propose a combination of the theories of Taylor and of Becker-Orowan. The new theory, it is claimed, also explains the increased plasticity of rock-salt in process of solution, ascribing this behaviour to a surface effect, as against Smekal's hypothesis of internal cracks.

Nickel-iron wires of high permeability show an abnormal 'skin effect' (mainly surface conduction, owing to increased internal resistance) for low audio-frequencies. An external magnetic field increases the resistance. Dr. E. P. Harrison, G. L. Turney and H Rowe give graphs showing the variation of the resistance with current strength and with the external magnetic field.

The presence of powdered glass changes the course of polymerisation and decomposition of formaldehyde (at temperatures up to 317°), producing carbon dioxide instead of carbon monoxide and water. Dr R. Spence interprets this effect as due to the breaking of the reaction chains owing to deactivation of active molecules by collision with increased surface.

Research Items

Giant Hand-Axe from Sheringham, Norfolk An altogether remarkable and gigantic hand-axe, discovered embedded in the beach below Beeston Hill, Sheringham, by Mr J P T Burchell, has been figured and described by Mr J Reid Moir (*Proc Prehistoric Soc East Anglia*, 7, Pt 3) The implement measures in its greatest length 15½ inches, in greatest width 6½ inches, in greatest thickness 5½ inches Its weight is approximately 14½ lb It was derived originally from the base of the Cromer Forest bed, which rests upon the surface of the chalk The implementiferous bed runs in beneath the Forest Bed strata and the glacial deposits which form the cliff, some 200 ft in height. The material of the axe is of flint, the colour of the flaked surfaces being jet black The ridges and outstanding parts are abraded, and it is striated in places There is a small area of the cortex remaining, which shows a ferruginous staining It is a specimen of the 'platessiform' type, that is, rhomboidal in section in the anterior portion and showing the remains of both the dorsal and ventral planes or platforms of the rostro carinate stage In two other specimens cited for purposes of comparison, coming from East and West Runton, one is clearly of the 'platessiform' type, but the ventral plane is partly transformed into a cutting edge, while the second is equally clearly of the 'batiform' type, in which the section through the anterior portion is triangular in section, the lower angles of the triangle representing the cutting edges Hand-axes showing these characteristics have been discovered not only in England but also widely distributed over the earth's surface The numerous specimens discovered in the basement bed, belonging to the early Pleistocene epoch, are as highly specialised as are those of any later prehistoric period and represent a very definite and necessary stage in implemental development No adequate explanation of the purpose which the gigantic size of the Sheringham axe could serve has been offered

Racial History in Scandinavia. Dr Stanislas Zejmzejmis has constructed an anthropological map of Scandinavia, and from this has reconstructed the racial history of the peninsula in the light of archæological and historical material. He has drawn his anthropological data mainly from military statistics and other published material, which he has analysed in accordance with the anthropological methods of Czekanowski (*L'Anthropologie*, 45, 1–2) The existence of four physical types is established as 'fundamental' in the sense of Czekanowski Mediterranean, Nordic, Lapoid and Armenoid The Mediterranean provinces, which play an important part in the peninsula, are centrally situated at Dalecarlia in Sweden, and Hedmark and Oppland in Norway They are surrounded by provinces of transition in which the Mediterranean type diminishes in favour of the Nordic or Lapoid. The essentially Nordic provinces form not one, but two zones, the first in southern Sweden (Skaraborgs, Jänköpings, Oestergötlands, Göteborgs, Aelvsborgs), the second in Norway (North and South Tröndelag), lying on each side of the lenticular centre. Outside these provinces are territories in which is found a strong proportion of the Lapoid element In the north of Norway (Tromsø and Finmark) this reaches as high as 33 per cent In Sweden the proportion is not so great, in the south, Scania and the adjacent regions correspond to the Norwegian Rogaland The Armenoid does not play an important part, and nowhere does it exceed 3–5 per cent The most ancient stratum of the prehistoric population (for example, Stagenas of the Ancylus period) is Mediterranean, possibly Cro-Magnon It is followed by the Lapoids of the south, who possibly are to be related to Ofnet The northern Lapoids are distinct and later, being Laps The Nordics appear with the last great neolithic migration into Scandinavia The brachycephals of southern Scandinavia are to be closely associated with Maglemose and the Danish kitchen middens The Nordics belong to the following *Littorina* period when the climate of Europe, becoming drier, was favourable to their nomadic habits The Norwegian Nordics are of secondary origin The Armenoids appear to have arrived at the end of the neolithic or beginning of the bronze age

Spearman's General Factor in Mental Activity. *Character and Personality*, 3, No 2, contains an article, "On the Nature of Spearman's General Factor", by Prof Wm McDougall He presents Prof Spearman's case for the existence of a general factor, usually represented by the letter *G*, which enters into all mental activity and is revealed in mental testing, and he considers the problem of determining the nature of *G* Two questions arise First, in what kind of operation does *G* most clearly manifest itself? Secondly, what is the underlying cause or condition which thus manifests itself? To the first question a satisfactory answer can be given, but the second presents a number of problems Spearman favours "a quantity of intellective energy" as the answer McDougall criticises this view, and suggests that both the supply and the direction of energy should be considered, and that a definition of *G* as "power of effective concentration of energy" is nearer the truth. The study of the effect of emotional excitement on cognitive activity, and the lack of any common factor so far from tests on animals, leads to the conclusion that 'integration' is the answer to the problem "In proportion to the degree of integration achieved the whole mind works as one system which dominates and controls all its parts" Prof. McDougall does not claim that his solution is final, but his arguments are stimulating and convincing

Chinese Fishes. In the *Journal of the Shanghai Science Institute* (Section 3, vol 1, 1934), Mr Shigeru Kimura publishes a "Description of the Fishes collected from the Yangtze-kiang, China, by late Dr. K. Kishinouye and his Party in 1927–1929" The collection is very large and of considerable interest, coming from the tributaries of Yangtze-kiang, from Szechwan Province, and consisting of fishes belonging to 63 genera and 28 families There are among them 11 new species, one of which is a handsome member of the Salmonidæ, *Hucho bleekeri*, represented by one specimen only from a mountain stream The name *Hucho* is from *Hu yu*, meaning tiger-fish, a name given by the natives to various different forms Seven new species belong to the Cyprinidæ, and one each to the Cobitidæ, Siluridæ and Bagridæ. The paper is well illustrated by plates in black and white, and there is a map showing the localities from which the material was collected.

Crustacea of the Vanderbilt Expeditions. The fifth volume of the "Scientific Results of the World Cruise of the Yacht *Alva*", 1931, with William K Vanderbilt commanding, deals with Crustacea (*Stomatopoda* and *Brachyura* By Lee Boone *Bull Vanderbilt Marine Mus*, 5, 1934 Huntington, L I, New York, U S A Printed Privately) It describes the zoological material personally collected by Mr Vanderbilt during a series of cruises in his yachts, and deposited in his marine museum The latest collections were made by the yacht *Alva*, and the present work is as beautifully printed and illustrated as were the former volumes Miss Lee Boone describes every species in detail, many of them being very rare, citing the type of each and where it is to be found, its distribution and reference to previous descriptions There are three new species of crabs *Actæomorpha alvæ*, an interesting form representative of a little-known genus of the family Leucosiidæ and resembling in appearance the cancroid genus *Actæa* · *Lissocarcinus elegans*, a new swimming crab connecting the sub-family Caphyrinæ with the Lupinæ and *Actæa aphrodita*, a pretty little crab from the coral reefs of Bali Colour plates and notes of several forms were made at the time of collecting by Mr W E Belanske, staff artist of the expedition, under the direction of Mr Vanderbilt, and are deposited in the Vanderbilt Marine Museum

Storage of Avocado Pears As Memoir No 1, the Low Temperature Research Station of the Imperial College of Tropical Agriculture publishes a study of storage possibilities with Avocado pears, which includes points of both scientific and commercial interest. The authors, Dr C. W Wardlaw and Mr E R Leonard, point out that most of the orchards of this plant in the West Indies are stocked with plants grown from seed so that there is great variety in the produce, a diversity which extends to their behaviour in storage conditions and makes their behaviour quite impossible to predict in relation to an export trade They emphasise, therefore, that the first step, if an export trade is to be built up, is to select certain definite varieties, which these preliminary tests show to possess possibilities, to use these only for purposes of propagation, and to study the behaviour of experimental consignments of these varieties under export conditions It is suggested that these preliminary exports should be kept at a steady temperature of 45° F At this temperature many of the local varieties manifest phenomena of 'chilling' which have considerable interest. Maturation processes still continue in the internal tissues in these chilled fruits, but the biochemical processes take an abnormal trend. The onset of chilling is shown to be closely associated with a phase of the process of ripening in the fruit.

Taxonomy of Wild Hybrids. In his presidential address to the Botanical Section of the American Association for the Advancement of Science (*Science*, 81, 161), Prof K. M Wiegand discussed the subject of wild hybrids from the taxonomic point of view. He cited his experience with the genus *Amelanchier* in eastern North America, in which, after many sortings of herbarium specimens, he finally reduced them to six piles (species) and a seventh pile including heterogeneous forms with intermediate or combination characters, local distribution and other features of hybrids In Newfoundland, where the conditions had been disturbed by forest cutting, a mixture of hybrids was found, but in less disturbed areas the plants were more uniform The conditions of hybridity in various other genera, such as *Crataegus*, *Rubus* and *Quercus*, are discussed, and it is concluded that hybridisation has probably played little part in evolution The eastern American species are regarded as nearly all going back to the Glacial period or much earlier, and species formation as a very slow process While this doubtless contains much truth, it is possible that the evolutionary importance of polyploidy, and particularly amphidiploidy, has been underestimated

Life-History of *Endophyllum sempervivi*. A very full account of the life-history of a rust fungus on house-leek plants has recently been published by Dorothy Ashworth (*Trans Brit Mycol Soc*, 19, Part 3, 240-258, February 1935) Investigations have been made into almost all the phases of activity of the fungus Binucleate sporidia germinate to form germ tubes, which penetrate the epidermal walls of the host Uninucleate mycelium is produced, and spermagonia appear in spring Masses of æcidial primordia occur at the base of each spermagonium, and after the production of secondary primordia, the hyphæ become binucleate by nuclear migration Æcidiospores formed from these mycelial threads have four nuclei, and give rise to a tri-septate promycelium from which four sporidia or basidiospores are abstricted It is interesting to note that æcidia can be formed without the intervention of the spermatia, diploid mycelium can be produced as a result of hyphal fusions *Endophyllum sempervivi* is a perennial fungus, and the mycelium appears to be always uninucleate until æcidia begin to develop It is not typical of the rust fungi in that æcidiospores produce basidia directly, without the intervention of uredo- or teleuto-spores

Ship Waves T H. Havelock (*Proc Roy Soc*, A, April 10) has made some calculations on the wave making resistance of simplified ship forms, taking into account fluid friction. In the absence of fluid friction, the energy absorbed in making waves is the same whether the model is moving bow first or stern first, even when the model is not symmetrical fore and aft The main effect of fluid friction is to lower the relative wave-making effects of the after parts of the surface, and in some cases calculated the effectiveness of the stern is lowered by about 40 per cent This reduction introduces a difference between the wave resistances for ahead and astern motion Calculations are also made of the wave profile using the corrections for fluid friction, and these agree well with observation

Rotation of Molecules in Liquids. X-ray studies have shown that the molecules of a liquid possess a spatial distribution comparable with that occurring in a crystalline solid The centre of gravity of a liquid molecule can be imagined as oscillating about a point which is itself slowly moving Furthermore, there exists a coupling between neighbouring molecules, and hence the latter cannot be considered as completely free to rotate. Instead, they are constrained to perform rotatory oscillations about an axis the orientation of which varies slowly. The effect of this constraint on the molecular polarisation and the Kerr effect of a liquid substance has been examined by P. Debye (*Bull Classe Sci.*, *Acad. roy Belg*, 31, 166; 1935). The calculation shows that the coupling, measured by the energy required to rotate a molecule through 90°, is quite large, being as much as 10 kT for water. The fact that the

molecular polarisation and the Kerr effect of a substance in solution are both less than for the same substance in the vapour state also follows from the theory. Thus the effect of dissolving monochloro benzene in hexane is completely explicable on the basis of a coupling energy equal to 0·75 *kT*.

Negative Ions in the Glow Discharge. Little work has been done on negative ions in the glow discharge, and they are commonly neglected in theories of the discharge. J. L. Spencer Smith has carried out careful work on the glow discharge in iodine (*Phil. Mag.*, April and May, 1935), and he finds that in this vapour negative ions are present in large numbers and exert a strong influence. In one series of experiments various regions of the discharge were investigated by the Langmuir probe method, and an analysis of the probe currents showed that negative ions are present in numbers about equal to the positive ions. In further work, negative ions from the discharge were drawn through a perforated probe electrode into an independently exhausted space and analysed by a magnetic field. I^-, I_2^- and I_3^- ions were found. The beams of negative ions obtained in this way were used for some approximate measurements of the collision probability between negative ions and neutral iodine molecules by measuring the absorption of the beams in iodine vapour.

New Method of Distinguishing Amylases. Basing himself upon the observations of Wijsman (*Rec. Trav. Chim.*, 9, 1, 1890), K. Venkata Giri has recently suggested a simple qualitative method of characterising different amylases which may prove to have a wide range of usefulness (*J. Indian Inst. Sci.* 17A, 11, 127–129). A small drop of the enzyme is added to an agar gel carrying a suspension of starch and allowed to diffuse for 24–28 hours at laboratory temperature. The gel is in a Petri dish, and at the end of this period a dilute solution of iodine is poured on for a few minutes, until the diffusion zones show clearly. In the case of β-amylase the central diffusion zone is coloured violet; in the case of α-amylase it is colourless. The results of its use with taka-diastase, salivary amylase and pancreatic amylase are described.

Standard Methods for Testing Wood Preservatives. In 1930, a conference was held in Berlin to discuss the possibility of arriving at a standard method for testing the toxicity of wood preservatives in the laboratory. At this conference there was general agreement as to the form which the tests should take, and a report of the decisions taken was published in NATURE (126, 921, 1930). A committee was set up at the meeting to organise a series of co-operative tests to determine how far the suggested method could give consistent results when carried out in different laboratories by different workers, and to settle details of technique. The results of the committee's work have been published in *Angewandte Chemie* (48, 21; 1935) in which is given an account of the experiments made in order to compare the activity of various isolations of the different test fungi chosen, and of the results obtained in different laboratories in comparative tests on identical samples of sodium fluoride and creosote. A detailed description of the standard method adopted for carrying out the recommended wood block test (*Klötzchenmethode*) is also included, together with a note on the 'agar' method (*Rohrchenmethode*). It is to be hoped that, in future, laboratory tests upon the toxicity of wood preservatives will be carried out, so far as possible, by this standard method, so that results obtained in different laboratories may be directly comparable.

Boundary Friction of Oxidised Lubricating Oils. Dr. Redgrove's paper on the "Boundary Friction of Oxidised Lubricating Oils", read before the Institution of Petroleum Technologists on April 9, is in fact an account of experiments conducted during the period 1927–31. Conclusions then reached agree substantially with those obtained as a result of more recent research, even though the particular problems under consideration were attacked from an entirely different angle. Since small percentages of the higher fatty acids improve lubricating qualities of mineral oils under boundary conditions, experiments were made to ascertain whether the less volatile petroleum acids exerted a like beneficial effect. Preliminary investigations with blends of a mixed base distillate oil and 1 per cent of fatty acids showed that there was a definite variation of coefficient of friction with temperature. A special apparatus was, therefore, designed in which temperature could be rigidly controlled, and results proved that the lower molecular weight fatty acids do not reduce the coefficient of static friction of mineral lubricating oils under boundary conditions. Moreover, they showed that the true criterion of lubricating values is rather the effective length of the hydrocarbon chain, normal to the *bearing surfaces, attached to the adsorbed* polar group, than the volume of the molecule. The greater the length of this hydrocarbon chain, the greater the flexibility of adsorbed molecules. Such a theory in conjunction with thermal vibration explains the low coefficient of friction of mixtures containing the higher molecular weight saturated fatty acids. Certain oxidation products of mineral lubricating oils are believed to be multipolar, and to them is due the elimination of the friction/temperature rise normally characteristic of non-oxidised mineral lubricating oils. If, however, asphalt is formed and deposited on the bearing surfaces as a result of the oxidisation, then an increase in the coefficient of static friction is likely to occur.

Systematic Displacements of Lines in Stellar Spectra. The radial velocity of a star as *determined from the* line displacements in its spectrum is found to depend slightly on the lines chosen for measurement. The lines of different elements give different results, though in general these differential effects are only very small. They may be caused by the influence of interstellar matter or by conditions in the stars themselves. The latter cause of the effect has been studied by Adams and McCormack (*Astrophys. J.*, 81, 119, 1935) in the case of nine stars of different types, all of which are sufficiently near to eliminate the effect of interstellar absorption. The chief lines affected are the *H* and *K* lines of calcium, the sodium *D* lines and a pair of Al I lines, all of which give systematic differences of the order of −5 km./sec. from the normal stellar lines. It is suggested that the hypothesis of a gradually expanding envelope surrounding the star affords the best explanation of these results. Three of the stars (including γ Cygni) are exceptionally interesting. The neutral Fe lines give larger results than those from ionised Fe, and Ce II gives larger values still. In such cases the hypothesis of radial convection currents affecting lines of different levels differently seems to be the only adequate explanation.

Iron and Steel Welding

THE enormous change in the general outlook on welding which has taken place during the last twelve or fifteen years was never so well exemplified as by the attendance of some nine hundred persons at the first meeting of the symposium on the welding of iron and steel organised by the Iron and Steel Institute with the co-operation of fifteen other scientific and technical societies, and held at the Institution of Civil Engineers on May 2-3 Sir Harold Carpenter presided, and pointed out that the whole question of welding had been raised by Dr H. J. Gough for the consideration of the Department of Scientific and Industrial Research

The object of the symposium was of a two-fold character It was designed in the first place, and mainly, to discover what is now known, and in the second place to map out fields of work for future development. Although welding is still in large measure an empirical art, a considerable amount of fundamental scientific work is now being done, and the results of this have been brought together in a collection of papers which represents by far the most important and comprehensive collection of information on the welding of the ferrous metals which has ever been made. The papers were divided into a series of groups, of which the first dealt with present-day practice and problems connected with welding in the engineering industries Shipbuilding, bridge and structural engineering, railway material and pressure vessels, formed one sub section of this group, the other dealing with the aeronautical and automobile industries, the production of chain, the electrical, heavy engineering and machinery industries and the welding of iron and steel castings and of wrought iron.

Group 2 was concerned with the practice and technique of welding, including the apparatus and plant required The metallurgy of welding, and the questions of specifications, inspection and testing formed Groups 3 and 4 It will come as a surprise to many to discover how much real research is being done, and how fundamental are the advances which are being made, at any rate in certain directions

From the various papers and discussions certain suggestions emerge regarding the lines on which future development and research might usefully proceed These include:

(1) The development of plant for electric welding in which the current is automatically adjustable to suit the rate of deposit, together with the necessary control of the arc

(2) Despite the work which has already been done, there are still very considerable gaps and discrepancies in our information regarding the factors which affect the fatigue resistance of all types of welded joints, particularly in comparison with similar solid, bolted or riveted constructions, and extensive research work on this point is most essential

(3) The investigation of the effect on the fatigue strength of various types of treatment and electrodes and the comparative influence of alternating and direct current

(4) The development of forms of welded construction which are based on a real knowledge of the fatigue properties of the welds for dynamically loaded structures (such as bridges)

(5) Work on the welding of the high carbon and alloy steels

(6) Work on non destructive methods of testing welded joints

No aspect of welding, so far as it is applied to iron and steel, was omitted from this highly successful symposium The most grateful thanks of producers and users of welded structures are due to those responsible for the meeting on one hand, and the authors of the papers on the other The only note of a critical nature which can possibly be struck is the fact that the material presented was of such enormous dimensions that the time available for its discussion was inevitably greatly restricted. A further discussion of this material at some future date would form a fitting corollary to the meeting already held.

F. C. T.

Royal Observatory, Greenwich

ANNUAL VISITATION

THE Astronomer Royal read his report to the Board of Visitors of the Royal Observatory, Greenwich, on the occasion of the annual visitation of the Observatory on June 1.

The construction of the new reversible transit circle has been completed by Messrs. Cooke, Troughton and Simms, Ltd., and the instrument is undergoing final tests. The construction of the two glass circles of 28 inches diameter, and the etching of divisions spaced at intervals of 5 minutes of arc have been carried out successfully. When completed, the new transit circle will be housed in the Christie enclosure next the Yapp 36-inch reflector. A contract for a slit spectrograph for use with the latter telescope has been placed with Messrs Adam Hilger, Ltd This spectrograph is designed for use with one or three prisms at will, the optical parts being made from ultra-violet glass giving good transmission down to 3500 A

During the year, 9,576 transit observations were made, including 130 observations of the sun and 94 of the moon. The observations of the moon continue to show a decrease in the correction to the longitude given by Brown's Tables, which were introduced into the *Nautical Almanac* in 1923. Nova Herculis was observed on the meridian six times above pole and twice below pole. The position for 1935·0 is α 18^h 5^m $39{\cdot}85^s$, δ $+45° 50' 54{\cdot}2''$ (Epoch 1934·99). 42 plates were exposed on Nova Herculis in the slitless spectrograph attached to the Yapp 36-inch equatorial reflector All these have been calibrated for photometry, and where possible a comparison star has been included These plates will provide material for the study of the distribution of energy throughout

the spectrum. In addition, work has been carried out with the new telescope on the programme of colour temperature work

The spectrohelioscope at Greenwich was used on 179 days. A photometer has been added to the instrument in such a way that the intensities of prominences and bright patches on the solar disc can be measured in terms of the brightness of the undisturbed disc in wave-lengths outside the absorption line concerned Measures of prominences have been made both in Hα and Hβ Work on the intensities of the Fraunhofer lines has been commenced A hut has been built in the Christie enclosure, in which a 16-inch cœlostat has been mounted Sunlight is fed into the basement below the 36 inch equatorial, where it is analysed by a 4 inch concave grating

Magnetic observations have been carried out at Abinger throughout the year The mean values of the magnetic elements for the year 1934 are as follows

Declination,	W 11° 41 1′
Inclination,	66° 39 7′
Horizontal Intensity,	0 18533
Vertical Intensity,	0 42955

Some innovations have been introduced with the meteorological observations Regular observations of the amount of solid matter suspended in the air were commenced on July 1, 1934 In November last, the worst month, a mean weight of 178 mgm of solid impurity was found in each 100 cubic metres of air Compared with the figures recently published for the previous year at other stations, it would appear that the pollution at Greenwich is fully as great as that at any London station, and is not on the average surpassed by any reporting station in Britain, although in Central Glasgow the pollution is worse at the worst times of the day The gaseous pollution of the atmosphere by sulphur dioxide has also been measured daily from January 1, 1935

The mean temperature for the year was 51·9°, which is 2 4° higher than the average for 1841–1915. There were 79 entirely sunless days, and only 39 entirely cloudless nights, that is, nights on which Polaris left an unbroken trace on the night sky camera

A number of improvements have been introduced in the detailed working of the observations for time with the small reversible transit circle Three observers are employed, instead of one, and the observations are corrected for personal equation to the mean of three observers (It is hoped shortly to construct a personal equation machine and obtain absolute personalities) Again, the chronograph and relay system has been brought up to date, and an oscillograph is now used to determine lags in the reception of wireless signals The accordance between Greenwich time and that sent out by foreign observatories is now much closer than was the case a few years ago The mean difference for 1934 between Greenwich and Paris is $-0\ 018^s$, and that between Greenwich and Nauen is $+0\ 013^s$, the sign + meaning late on Greenwich

During the past year, Mr. Furner, assistant, retired after forty-six years' service, and Mr Blackwell was appointed junior assistant

Concluding his report, the Astronomer Royal referred to the atmospheric pollution, which hampers astronomical work Silvered mirrors and circles tarnish rapidly, and soot and grit are deposited A further difficulty is due to the increasing brightness of the sky at night, which results from the use of mercury lamps for street lighting Photographic work with rapid plates at low altitudes in the sky is impossible in certain directions in which the new lighting is extensively used, and representations have been made to the Greenwich Borough Council on the subject of street lighting

R v d R W

Alchemy and Music

THE first combined meeting of the Chemical and Musical Societies in the history of the ancient University of St. Andrews was held in the Chemistry Lecture Theatre of the United College, St Andrews, on April 24, when Prof John Read, professor of chemistry, delivered an illustrated lecture under the title "The Frankfurt Emblems . a Research in 17th Century Alchemy" The culminating event of the evening was the singing, possibly for the first time in three hundred years, of some unique alchemical music which Prof. Read encountered some time ago in his alchemical studies, and which has formed the subject of a recent research by Mr F H Sawyer, lecturer in music in the University of St Andrews

Alchemy, said Prof. Read, has been variously defined as the pretended art of transmuting base metals into gold, as the chemistry of the Middle Ages, and so forth ; but in its broadest aspect it was a system of philosophy which claimed to penetrate the mystery of life as well as the formation of inanimate substances. Like modern science, alchemy had its theories, notably the theory of the four elements, with the allied conception of the Philosopher's Stone, and the sulphur-mercury theory of the constitution of metals. Alchemical theory, however, like alchemical symbolism, is a complex and intricate subject, rendered even more difficult by its protean character of change The age of alchemy extended approximately from the early years of the Christian era until the end of the seventeenth century

Among many features of interest in the declining years of alchemy are the piquant illustrations, so racy of the alchemical soil of the seventeenth century The Twelve Keys of the mysterious Basil Valentine, in particular, were handled repeatedly by new artists, who provided them with an honoured place in alchemical publications of this time Each of the Keys consists of an emblem with an allegorical description.

Judging from the age-long popularity of Ben Jonson's play, "The Alchemist", which was first produced in 1610, there was a considerable public throughout the seventeenth century for attractive expositions of alchemy Frequenters of the playhouses of those days were familiar with that technical language of contemporary alchemy and astrology which is so much 'heathen Greek' to the modern playgoer. Thus, the production of titillating alchemical works, abounding in pictorial illustrations, came probably as a response to a wide demand

The first issue of the Basilian emblems appears to have been made from Frankfort , and other

notable alchemical works with similar pictorial embellishments were published, either in their original or later editions, from this famous centre of early book illustrations There was method in this apparent madness of obscure expression, as Basil Valentine remarked, the obscurity of expression was imperative because the substance of the magic Philosopher's gold-making Stone was within reach of everyone, "and there is no other way of keeping up the divinely ordained difference between rich and poor" If alchemy had survived, remarked Prof. Read, it would have become political

Certain works published at, or near, Frankfort during the seventeenth century, largely under the name of Michael Maier, are rich in such allegorical illustrations, which Prof Read terms for convenience "the Frankfurt Emblems" This Michael Maier was a very remarkable man Besides being a musical alchemist, he became physician and private secretary to the Emperor Rudolph II at Prague, and apparently occupied a high position in the Society of Rosicrucians, or Brethren of the Rosy Cross The publishing firm of Lucas Jennis, of Frankfort, took a prominent part in issuing the works in question, several of which were reviewed in some detail by Prof Read. The emblems were often provided with a Latin epigram, together with a cryptic title and a discourse in the same language "Atalanta Fugiens" ("Atalanta Fleeing"), published by Michael Maier at Oppenheim in 1618, contains fifty such epigrams set to music by the versatile author These so-called 'fugues' are in reality rounds or part-songs for three voices, bearing a marked general resemblance to the well-known, but less dignified, "Three Blind Mice" In allusion to the classical legend of Atalanta and the golden apples, the three parts are quaintly termed "Atalanta, or the Fleeing Voice", "Hippomenes, or the Pursuing Voice", and "The Apple in the Path, or the Delaying Voice"

At the end of Prof Read's lecture, Mr Sawyer, who has made a detailed study of this unique alchemical music, explained its construction and characteristics, after which some of the canons were sung under his direction by members of the St Andrews University Musical Society It is to be presumed that these 'incantations' were intended to be sung at critical moments during the concoction of the Philosopher's Stone, such operations being directed also by prayer and astrological influences In one of the 'fugues', for example, the Stone is likened unto coral, and the epigram opens in the following words

Planta maris vegetans Siculi sub fluctibus uda
Ramos sub tepidis multiplicavit aquis

Or, in English, "The plant of the sea, flourishing moist under Sicilian waves, has multiplied its branches beneath the warm waters " Another 'fugue' takes as its theme the thesis that "Fire loves not gold-making but gold". The music had a quaint and appealing quality which seemed to accord with its esoteric purpose.

Prof Read's illustrative lantern slides, made from the original engravings, included a contemporary representation (1609) of an alchemical laboratory, displaying a selection of musical instruments among the stills and furnaces, with an attached legend stating that "music disperses sadness and malignant spirits".

University and Educational Intelligence

CAMBRIDGE —It is announced that the Museum of Zoology will shortly benefit from the bequest of the late W. D. D Crotch. The capital passing to the University is about £6,000, and a Grace recommending that a new endowment be added to the Crotch Fund, created out of the bequest of his brother, the late G R Crotch, will be submitted to the Regent House

Mr J. T Saunders, of Christ's College, has been appointed a member of the Freshwater Biological Association of the British Empire.

The Gordon Wigan Prize in chemistry for 1934 has been awarded to J E Carruthers, of Emmanuel College, for a dissertation entitled "The Photo-oxidation of Gaseous Formaldehyde"

Prof O T Jones has been appointed to represent the University on July 3 and the following days at the opening of the new Museum of Practical Geology and at the celebration of the centenary of the Geological Survey of Great Britain

The following representatives of the University at conferences abroad have been appointed —Prof. A C Seward, Master of Downing, professor of botany, at the Botanical Congress, Amsterdam, next September, Prof E H Minns, Disney professor of archæology, and Mr L C. G Clarke, curator of Museum of Archæology and Ethnology, at the tercentenary of Peter Pazmany University, Budapest, next September; and Prof G H F Nuttall, emeritus professor of biology, at the tercentenary of the French Academy this month

LONDON —The Court has received gifts towards the Ceremonial Hall to be built on the University site in Bloomsbury from the Worshipful Companies of Needlemakers, Carmen and Spectacle Makers The City Corporation has made a grant of £5,000 (spread over five years) to Birkbeck College towards the new College buildings also to be erected on the University site in Bloomsbury. The Chadwick Trustees have renewed their grant of £200 a year for three years in aid of the Edwin Chadwick Department of Municipal Engineering and Hygiene at University College, and Messrs Bovril, Ltd, have instituted at King's College two research studentships in physiology at £350 a year, and will defray in addition the cost of the special materials, apparatus and assistance needed

The Principal of the University of London announces, in his report on the work of the University during 1934–35, that the first block of the buildings in Bloomsbury, of which the foundation stone was laid by His Majesty the King two years ago, should be ready for occupation next year. This block is to contain the Senate House, administrative offices and part of the library Presumably, therefore, next year will see the removal of the University's home from South Kensington, where it has been sheltered for so many years by the Imperial Institute Towards the finance of the great building scheme the local authorities are contributing sums amounting in the aggregate to £700,000. Gifts promised by the City of London Corporation and forty-six of the City Companies towards the cost of the Great Hall reach a total of £174,000, while the Goldsmiths' Company is giving £50,000 towards the new building for the Goldsmiths' Library. Among many other benefactions mentioned in the report is an undertaking by the Carnegie Corporation to provide 22,000 dollars a

year for three years for the Institute of Education, to aid in the development of the Institute's relations with students from the Dominions and Colonies, this is to be used for short-period fellowships for students from the Dominions and for payment of a university teacher from the Dominions to act as "Adviser to Overseas Students" An interesting and important development on the 'external' side of the University concerns the recognition of colleges for the purpose of the external degree in engineering As external candidates will in future have to submit course work carried out in an approved institution, colleges in various parts of Great Britain have applied for, and forty-two have already obtained, approval for this purpose Certain overseas colleges are contemplating similar action.

OXFORD.—Mr T W Chaundy has been reappointed lecturer in mathematics for five years from October 1. Mr C N Hinshelwood, Dr A S Russell and Mr H J George have been appointed, or re-appointed, lecturers in chemistry for the same period

Dr. Donald Pollock has undertaken to provide £500 a year from October 1 towards the stipend of the Donald Pollock reader in engineering science, a new readership

Congregation on May 28 recorded its thanks to the Czechoslovak Government for its loan six months ago, for three years, of 1,636 mgm of radium for use in the Clarendon Laboratory

Degrees of D C.L , *honoris causa*, will be conferred on June 26 on Lord Bledisloe, Sir Herbert Samuel and Sir John Reith, and the degree of D Sc on Prof. Peter Debye

The Romanes Lecture on "Then and Now or the Changes of the Last Fifty Years" will be given on June 14 by Prof Gilbert Murray

Science News a Century Ago

Death of Edward Troughton

Edward Troughton, the famous Fleet Street instrument maker, whose name is still borne by the firm of Cooke, Troughton and Simms, Ltd , died on June 12, 1835 Like the other eighteenth century mechanicians Sharp, Graham, Bird and Ramsden, Troughton came from the north, being born in Corney, Cumberland, in 1753 At first brought up to farming, at seventeen years of age he became an apprentice to his older brother John in London, and the two for a short time were partners as mechanicians. On his brother's death, Troughton carried on the business alone until 1826, when he took into partnership William Simms (1793–1860) So early as 1778, Troughton had introduced a new method of graduating arcs of circles, which was eventually to lead to the award to him of the Copley Medal, and he gradually gained a reputation as an instrument maker second to none Instruments of his were erected in observatories at Paris, the Cape, St. Helena, Madras, Cracow, Cadiz, Brussels, Edinburgh, Cambridge and Greenwich.

A man of simple and frugal habits, Troughton was never married, and towards the end of his life, it is said, he was seldom absent from his dingy parlour at 136 Fleet Street, London, where he sat with a huge ear trumpet at hand, wearing clothes stained with snuff, and a soiled wig. Elected fellow of the Royal Society in 1810, he was an original member of the Royal Astronomical Society, and a marble bust of him by Chantrey, subscribed for by his friends, was placed in the Royal Observatory, Greenwich His grave is in Kensal Green Cemetery.

Wilkinson on Gunpowder

According to the *Athenæum* of June 20, 1835, the Friday evening meetings of the Royal Institution for the summer closed on June 12 with a lecture on the history and manufacture of gunpowder by Mr. Henry Wilkinson, who had on several former occasions delivered lectures on warlike machines of the ancients, etc Mr Wilkinson was of opinion that gunpowder was known to the ancients, and that it was highly probable that Alexander the Great actually met with gunpowder and firearms in India. He quoted the Gentoo laws to show that they contain a prohibition of gunpowder and firearms, and from this and other authorities referred to, he seemed to be of opinion that gunpowder had been known in China and Hindustan, far beyond all period of investigation His lecture was accompanied by some interesting experiments on the action of fulminating powders on gunpowder

Progress on the London and Greenwich Railway

In the *Mechanics Magazine* of June 13, 1835, is a communication from a correspondent who wrote "On Monday last a number of shareholders and directors of this undertaking met at the works near the Blue Anchor-road to witness the experimental running of the Company's locomotive engine 'The Royal William' A distance of one mile was performed in about four minutes A glass of water, filled to the brim, was placed on the block holding the rail, to ascertain the degree of vibration, when the engine, with the tender with water and coal, and several passengers, the whole train weighing at least 14 tons, passed along Not a drop of water was spilled, nor was any vibration perceptible Persons who stood under the arches when the engine passed over, were astonished to find that the noise was no greater than what would be occasioned by the passing of a hackney coach"

Airy and the Royal Observatory, Greenwich

In the latter part of 1834, Airy, then at Cambridge, had been asked whether he would accept the office of Astronomer Royal, but a change of Ministry caused a delay in the negotiations The various steps which finally led to his appointment are given in his autobiographical notes for 1835 "The Ministry," he wrote, "had again been changed in the spring, and the Whigs were again in power On June 11th Lord Auckland, who was again First Lord of the Admiralty (as last year) again wrote to me to offer me the office of Astronomer Royal, or to request my suggestions on the filling up of the office On June 15th I wrote my first reply, and on June 17th wrote to accept it On June 18th Lord Auckland acknowledges, and on June 22nd the King approved." On August 13 Airy had a meeting with Lord Auckland and Mr Charles Wood, the Secretary of the Admiralty "At this meeting Lord Auckland and Mr Wood expressed their feeling, that the Observatory had fallen into such a state of disrepute that the whole establishment ought to be cleared out I represented that I could make it efficient with a good First Assistant , and the other Assistants were kept. But the establishment was in a queer state ." Airy took charge of the Observatory in October 1835, having for his first assistant Robert Main

Avebury—the Nation's Responsibility

AN interest in the preservation of areas of natural beauty or historic interest, now widely diffused among the public, affords hope of the success of an attempt which is being made to secure the famous site of Avebury and its immediate neighbourhood in Wiltshire from vandalism once and for all, and to promote its further archæological exploration

Of the importance to the prehistorian of the site at Avebury there can be no question Even in the unlikely contingency that future excavation should bring no additional monuments to light, Avebury as it stands, with its satellites, constitutes one of the most imposing assemblages of the work of prehistoric man, not in Britain alone, but in the whole of Europe The circle itself, with its three rings, is the largest known to exist It covers twenty-nine acres of ground and is surrounded by a rampart and a fosse, now mostly silted up, three quarters of a mile in length An avenue a mile long leads from one side to the remarkable sanctuary on Overton Hill This avenue was marked by standing stones, but many are missing or fallen The missing members are being sought underground by Mr Alexander Keiller, and as they are found are being replaced Even this work of exploratory repair has thrown fresh light on the cultural history of the settlement A similar avenue of like length may have led from the circle in almost exactly the opposite direction This too may prove a guide to future discovery

The remains directly linked with the circle by no means exhaust its archæological context At a distance of a mile to the north-west lies the camp on Windmill Hill, which Mr Keiller's recent excavations have made a *locus classicus* in the annals of archæology , and at the same distance to the south is Silbury Hill, of which the bare statement that it is the largest artificial circular mound in Europe gives little idea of the impressiveness of its height and mass Nearby are the East and West Kennet barrows, the largest long barrows in Britain Both long and round barrows are numerous in the area ; and not far away stands Stonehenge.

The mere enumeration of the monuments of the area is a sufficient indication of its pre-eminence in early cultural development, while their size and construction, necessitating the preparation, transport and erection of these great blocks of stone, as well as excavation on a grand scale,

must have involved an organisation of labour and an engineering skill such as could have been possible only at a point of concentration of a relatively large population over a considerable period of time It requires little exercise of the imagination and no straining of the facts to see in Avebury a great centre of early tribal and religious activity. Lying on the periphery of European prehistoric culture, it is the meeting place and the goal of lines of ethnic and cultural migration, of which the paths across Europe are now emerging as the result of recent archæological research Already at Avebury and in the neighbourhood, excavation has established a cultural succession in the neolithic and early bronze ages of the third and second millennia before our era, which eventually may afford a clue to the causes which led to this great efflorescence of cultural development and the reason why it should have taken place precisely at this point.

Mr. Ormsby-Gore's appeal on behalf of Avebury, in *The Times* of May 31, is an exceptional measure to meet a difficult situation As a Minister of the Crown and the responsible head of the department which has been entrusted by Parliament with the protection of our ancient monuments, he presses urgently for the co-operation of the public in the preservation and further exploration of this centre of ancient civilisation By his action, the future of Avebury has been raised to the status of a national problem. Normally, the Office of Works does not take action in such matters except on outside representation; nor do its powers to protect ancient monuments under schedule extend, except in certain conditions, to ensuring the preservation and systematic and scientific investigation of the evidence which lies beneath the surface of the ground Hence in the conflict of private ownership and scientific and historic interests, the latter, even in the face of public protest, may go to the wall It is with the object of averting this catastrophe at Avebury that Mr. Ormsby-Gore has intervened to urge the need for immediate powers to control the future of the site.

At present, exact and scientifically assured knowledge of Avebury and its surroundings covers only a small part of the field; and an intensive exploration of a considerable area is essential before anything like a comprehensive view of its development will be possible Mr. Ormsby-Gore, indeed, holds that this investigation is of such moment that it should take precedence of all other schemes; and he couples Avebury with the Roman Wall as being of international importance. Further, he stresses the danger which threatens the character and archæological development of the site through the erection of "haphazard bungalows, petrol pumps, or other less desirable forms of our ephemeral twentieth-century 'development' ".

The danger is acute Mr Ormsby-Gore points out that the Office of Works has effective 'guardianship' only over Silbury, the West Kennet Barrow and the sanctuary on Overton Hill, and although the stones now standing or lying above ground are 'protected' under schedule, the land which everywhere may cover precious evidence of this great neolithic civilisation is in the hands of small landowners, who not unnaturally are desirous of making the most of their opportunities

What is the remedy? Mr. Ormsby-Gore is anxious that the urgent work of conservation and further exploration should proceed forthwith, and suggests the immediate application of a scheme under the Town and Country Planning Act For this it would be necessary to secure joint action on the part of the local authorities of Wiltshire, the owners and the Office of Works itself, as well as the support of "the various public bodies interested in the progress of British archæology" While local bodies in Wiltshire will no doubt be sufficiently public-spirited to lend the weight of their authority, private owners may be less ready to acquiesce if the scheme involves serious interference with their rights to deal with their own property.

Without details it is impossible to say how far this method of procedure is likely to attain adequate preservation of the antiquities in the area and ensure the facilities necessary for future research. Under existing legislation, archæological exploration would seem to be a necessary precedent condition of effective protection, and this will be both a lengthy and a costly business If Avebury is of international importance as Mr Ormsby-Gore maintains—and no archæologist would be prepared to deny this contention—its possession by Great Britain imposes upon the nation a duty not only of maintaining the area in a condition worthy of its character and history, but also the duty of making accessible its full evidential value in the history of European civilisation—in other words, of assuming the responsibility for its exploration. Avebury and its

surroundings should be made a national possession and a reserve under Act of Parliament much as is the Yellowstone Park in the United States and a sum should be set aside annually in the provision for the Office of Works for its archæological investigation As the system of farming in Wiltshire is not such as need interfere with the character of the area as a setting of archæological remains rents under Crown holdings would reduce the cost of such a scheme In such a way but scarcely otherwise would this generation carry out to the full its obl gati n to posterity

Reviews

Vitamin Research

Methodik der Vitaminforschung Von Dr Christian Bomskov Pp xvi+301 (Leipzig Georg Thieme 1935) 24 gold marks

THIS is a book that can be recommended without any hesitation or qualification to all those who are concerned with biological chemical or physical assay of the vitamins So thoroughly has the ground been covered including even those portions of contiguous territory with which too many vitamin assayists seem to be unacquainted that it can be confidently recommended to all who are engaged in any kind of biological assay whatever The introductory pages being con cerned with the rearing and maintenance of a healthy animal colony emphasise however briefly *matters of fundamental importance to every* animal laboratory

On this question of an animal colony there is one sentence in the introductory chapter that almost deserves to be printed in letters of gold The author is discussing the spontaneous appearance of diseases in an animal colony and tersely remarks Die beste Prophylaxe ist immer noch die Sauberkeit im Tierstall He gives some interesting tables showing the different stock diets that have been proposed by different investigators and his tables showing the composition of different constituents will save many workers time in looking up figures and making their own calculations It is however curious that when stating the average weight of young animals produced on different diets recorded he makes no distinction between the pure albino rat and the pied or hooded animal, though it is well known to workers in this field that certain strains of the latter may have a growth rate and a final weight 50 per cent greater than those of the former It would obviously be quite unfair for example to condemn diet *A* because it permits in pure albinos less vigorous growth than diet *B* permits in pied albinos

Before directing attention to certain of the author's views and venturing to criticise some minor points it is necessary to point out that this is the only volume available on its subject and has therefore to be judged on its merits without odious comparisons Of the standard books on vitamins we recognise the English survey published by the Medical Research Council and the American Chemical Society s monograph by Sherman and Smith as authoritative and permanent The former lays naturally rather more emphasis on the clinical aspect than the latter which is written by and for chemists between them they give a comprehensive account of known facts and suspicions The vast monograph by Ethel Browning marred by a number of inaccuracies commands respect for its bibliographic completeness as also does the more limited but also more accurate bibliographical Survey of Vitamins published by Wodlinger in 1932 Besides these we have certain specialised books—for example Barnett Sure s Vitamins in Health and Disease Hess s monographs on rickets and scurvy Blunt and Cowan s Ultraviolet Light and Vitamin D in Nutrition —and a number of semi popular expositions but nobody has so far gathered together in one place an account of all the varying techniques employed in vitamin research The excellent series of papers by Jung in the *Zeitschrift fur Vitaminforschung* only occupies 54 pages and is confined to methods of assay in food and pharmaceutical products in Dr Bomskov s much more comprehensive publication all methods proposed by workers of standing have been described in detail and made to some extent the subject of critical consideration One can particularly admire the way Dr Bomskov has managed to produce by September 1934 (the date of his preface) a book that actually takes cognisance of the recommendations made by the Vitamin Conference in June of that year

We might it is true with advantage have had a rather more detailed discussion of the principles involved in vitamin assay Had this been done the curious understatement that in certain circumstances pure bred animals are to be preferred ' could have been made considerably clearer The change in methodology implied by the introduction of standard preparations into

vitamin assay should have been discussed explicitly, particularly since some German workers in the field have been amongst the worst sinners in depending upon animal reactions for their units of measurement.

After a general section, occupying 25 pages, there follows the special section of the book, in which every known vitamin is discussed separately In addition to A, D, E, B_1, B_2 and C, the author has thought fit to include a discussion of the "fat-soluble growth vitamin", by which he understands the "Coward factor", though his references also cover the work of Evans and Lepkovsky on the unsaturated fatty acid dietary factor, which is perhaps a rather unfortunate confusion In the water-soluble group he has included, besides B_1 and B_2, the following factors . B_6 (anti-pellagra), extrinsic factor or anti-sprue factor, B_3, B_4, B_5, F (reported by Sure, Kik and Smith, and possibly identical with the flavine factor), Chick and Copping's Y factor, the insoluble factor R of Hunt and Lewis and vitamin H of Györgyi, as well as the vitamin C_2 of Bezssonoff and von Euler Besides this miscellaneous collection of vitamins, some of them of distinctly dubious respectability, we find in the last two pages of the book a section entitled "Vitamins of Doubtful Nature", including such things as McCay's trout factor, the anti-paralytic factor of Keenan and colleagues, the growth factors of Mapson, Daggs, Seegers-Smith, Madsen, Norris, and Bethke, with a final allusion to Wesson and Murrell's carbohydrate-exchange regulating factor

The book is throughout profusely exemplified with tables and illustrations, the latter reproduced from original publications in various countries Dr Bomskov has adopted a sound, but rather unusual, course in reproducing most of his tabular matter in its original language, and has been remarkably successful in avoiding printer's errors during the process (A very few, such as "scaily tail", "Osteolin", and so on have been noticed) He has also inserted a number of tables of his own, as for example, the comparative list of vitamin B_1-free diets (p. 170), which includes seventeen variants proposed by twelve different workers or groups of workers

The book is, naturally, concerned predominantly with biological methods of assay, but the author has given an adequate account of such procedures as the chemical evaluation of reducing power, proposed by Tillmanns, Harris and others for assaying vitamin C, and has even included the Reichstein, Haworth and Micheel syntheses of ascorbic acid, for which he has used the configuration put forward by the Birmingham workers and now generally accepted. Again, he has given adequate recognition, following the findings of the 1934 Vitamin Conference, to the spectrophotometric method of assaying vitamin A, and does not overlook Chevallier's ingenious adaptation of this method.

Towards the end of each section on a particular vitamin, short special sections give information as to the requirements and storage of the vitamin in various animals, including man It is interesting to note that the author regards vitamin B_2 as consisting of a flavine growth factor, Gyorgyi's antipellagral B_6, and the extrinsic factor of Castle, a view that we do not think will find general acceptance at the present moment In the general section he also remarks, in passing, that on a particular stock diet of his own, the young animals have such large reserves of vitamin B_1 that they cannot be used for its investigation In view of current controversy, however, his discrimination between the flavines and the anti-pellagral factor seems to be more important than his assignation of the term "B_2" to the former

The book is extremely well served with references, the author has elected to place them at the foot of the pages to which they apply, and to dispense with the usual author index The subject index of twelve pages is perfectly adequate The high quality of Dr Bomskov's work has been ably backed by his publisher, though it is a pity that a book likely to be handled as often as this one should be published in paper covers

A. L. BACHARACH.

The Works of Huygens

Œuvres complètes de Christiaan Huygens, publiées par la Société Hollandaise des Sciences Tome 18 *L'Horloge à pendule ou à balancier de 1666 a 1695, anecdota.* Pp. iv+703. (La Haye Martinus Nijhoff, 1934) n.p.

THE eighteenth volume of the monumental edition of the works of Christiaan Huygens, in course of publication by the Dutch Society of Sciences, appears less interesting than many of its predecessors The reason for this impression does not lie in the value of its contents On the contrary, it is because the greater part of the volume is occupied by the classical work "Horologium Oscillatorium", which alone would have sufficed to establish the enduring fame of its author But this was the mature outcome of years of earlier research; the polished work is not only more familiar, but also the phase of creative effort has an interest which cannot be altogether sustained in a formal textbook, however original.

Huygens went to Paris in 1666, and nearly the whole of the following fifteen years were spent in the French capital He had been in intimate correspondence with some of the leading founders of the Royal Society, and he took a natural place, and soon a dominant place, in that group of men who, under the encouragement of Colbert and his royal master, founded the Paris Academy of Sciences. What constitutes the greatness of Huygens is the universal character of his outlook and method His distinction lies at once in observational science, in his mastery of physical manipulation and in natural philosophy The practical and the theoretical side of things shared his interest Hence his persistent and fertile efforts to improve the construction of the clock conferred a recognised benefit on mankind Yet the motive came from the recognition of the clock as a scientific instrument of fundamental importance, and this in turn led him from the contemplation of one type of mechanism to the profound study of the fundamental laws of dynamics

At heart, Huygens was devoted to the cultivation of science as a purely intellectual pursuit Geometry, which for him meant Euclidean geometry of course, was the key. But no man of science ever preserved a more harmonious balance between all those sources by which scientific truth can be revealed

As an acknowledged masterpiece of the first order, the "Horologium Oscillatorium" needs no description Published in 1673, it is cast in the classical mould in the true line of descent from the Greek geometers Although the main results embodied in the work were already in the possession of Huygens before he left Holland, as previous volumes of the present edition of his works have shown in detail, they had in many cases not been published in any definite form, if at all Hence the publication in the shape of a regular treatise constituted an event of capital importance in the history of science in general and rational mechanics in particular. Nothing else is needed to show the remarkable state of development which dynamical ideas had reached at the very moment from which we are accustomed to trace the Newtonian system of dynamics.

Huygens returned finally to Holland in 1681 The present volume, in addition to the capital treatise here presented in French and Latin versions, contains all the fragments of his work bearing on the perfection and performance of the clock between 1666 and 1695. Their interest is mainly of a controversial, or purely technical, kind rather than of a general character.

H. C. P.

British Marine Zoology

The British Sea Anemones By Prof T A. Stephenson Vol 2 (Ray Society Vol 121 for the Year 1934) Pp xii+426+16+plates 15–33. (London Dulau and Co , Ltd , 1935) 37*s* 6*d*

THE sea anemone fauna of Great Britain is now known much better than that of any other area in the world, largely as a result of the twenty years work that has been put into Prof T A Stephenson's magnificent monograph, just completed by the appearance of the descriptive volume

In addition to the very full accounts of anatomy and the references to all previous work, the author of this comprehensive monograph, although he was obliged to omit his contemplated review of actinian physiology and behaviour, has given many interesting descriptions of the animals' habits This has been facilitated by the comparative ease with which anemones can be maintained for observation in aquaria, a fact that is proved by the pathetic story of Mr Evans's *Actinia equina* during the War Left in an aquarium without food or aeration, in water that was becoming increasingly more salt through slow evaporation, the anemones held on until their owner's return, very much reduced in size, but still recognisable The palm for longevity under artificial conditions—seventy-three years—is held by the famous individuals of *Cereus pedunculatus* at present in the care of Prof J H Ashworth at Edinburgh

A few of the discussions of special interest that deserve notice are parasitism and burrowing habits in *Peachia* , the range of variation and the viviparous reproduction of the well-known and widely distributed *Actinia equina* , the colouring, reproduction and commensal algæ in *Anemonia sulcata* , autotomy of tentacles in *Bolocera* ; apparent suppression of tentacular feeding in *Aureliania* , the unusual action of the *Fangtentakeln*, and laceration in *Diadumene cincta* , the puzzle of the distribution, relation to environment, and original home of *D lucia* , dwarf races, laceration and planktonic feeding in *Metridium senile* ; resorption of tentacles in *Calliactis* , commensalism in *Calliactis* and *Adamsia* ; laceration in *Sagartia elegans* and *Actinothoe* ; and what may be regarded as neoteny in *Metridium senile* and *Sagartia troglodytes*

Lovers of the living things of the sea in particular will be grateful to Prof Stephenson for the help he gives them in the identification of the British anemones He provides not simply a key, the ends of which might be defeated by careless use, but a combination of a key and a summary

of the most important features The volume is illustrated by numerous and beautifully executed text figures of anatomy and patterning, as well as by eight more exquisitely drawn plates in colour and eleven plates of photographs Together with the charming and fanciful (if not strictly relevant) vignettes which terminate some of the chapters, they make the work one of artistic as well as scientific importance It is a critical and masterly account with a good bibliography of a difficult subject by one of the world's greatest experts who, although he has shown himself sympathetic with the demands of the modern schools of physiology and ecology, is not one of those who take lightly the responsibilities of the systematist.

A K TOTTON

Short Notices

Methods of Air Analysis By Prof J S Haldane and J. Ivon Graham (Griffin's Scientific Text-Books) Fourth edition, revised throughout and enlarged Pp vii+176 (London · Charles Griffin and Co , Ltd , 1935) 7*s* 6*d* net

ALTHOUGH it is twenty-three years since Dr Haldane's little book was first published, the methods and apparatus which he has described with such minute attention to detail are still in everyday use for the examination of air and mine gases With the collaboration of Mr J. Ivon Graham, the fourth edition has now been enlarged and admirably brought up to date without changing the general character of the book

Owing to the toxicity of carbon monoxide, much attention has been directed of late years to the determination of very small quantities of this gas, for which purpose the portable and laboratory types of apparatus used in the Mining Research Laboratory, Birmingham, and capable of detecting 0·0005 per cent are recommended

From the point of view of safety in mines, the new chapter dealing with the application of gas analysis to the detection of spontaneous combustion is of particular interest, the authors state that the analytical method is capable of greater sensitivity than the older one depending on smell

Another trend in the technique of gas analysis has been the development of specialised instruments such as the Hartridge reversion spectroscope and the Katz recorder for carbon monoxide, the McLuckie apparatus for inflammable gases, and the Owens dust collector, to mention only a few of those described in the present volume

Handbook of Chemistry : a Reference Volume for all requiring Ready Access to Chemical and Physical Data used in Laboratory Work and Manufacturing. Compiled and edited by Prof. Norbert Adolph Lange, assisted by Gorden M Forker. With an Appendix of Mathematical Tables and Formulas, by Prof. Richard Stevens Burington Pp. xiv+1265–248+29. (Sandusky, Ohio . Handbook Publishers, Inc., 1934) 6 dollars.

THE present reviewer has kept this handbook beside him for several months and has put it to the test repeatedly. It has met the requirements on every occasion, in chemical matters as well as in purely mathematical.

One of the best sections of the book comprises the 234 pages dealing with 4,452 organic compounds, for each of which is given a 'Beilstein' reference, in addition to the usual information This reference is a particularly useful feature as it enables the reader to find at once the page in the enormous and unwieldy Beilstein where he can obtain further information. The section on inorganic compounds extending to 112 pages is also very useful

In addition to the data given in the tables just mentioned, all the more important properties are given tables to themselves, and when only a limited list of substances is mentioned, the reader is directed where he can find a more complete list

Among the interesting and novel features are changes in atomic weights from 1894 until 1933 ; a large table of alloys (including heat- and corrosion-resisting alloys), classification of crystals ; organic reagents for inorganic analysis ; laboratory solutions ; hazardous chemicals and their handling There is a wealth of data covering not only a very wide field of pure chemistry (physical, inorganic and organic) but also every conceivable section of applied chemistry The information is also brought well up to date

It is impossible to give a complete catalogue of all the subjects treated in this valuable handbook, but great care seems to have been taken to make the information as complete and accurate as possible Further, considerable attention has been paid to the arrangement of the details, which will be found very convenient.

The Complete Book of British Butterflies. By F. W Frohawk. Pp. 384+32 plates. (London and Melbourne : Ward, Lock and Co., Ltd., 1934) 10*s*. 6*d*. net.

IT is now nearly thirty years since South's "Butterflies of the British Isles" was first published, and this, in its successive editions, has remained the best book on the subject for both the beginner and the more advanced collector. In 1929, Mr. Frohawk brought out his "Natural History of the British Butterflies", but the price of this was beyond most pockets. Mr Frohawk has now challenged the supremacy of South's book by re-issuing, in a cheaper form, the essential illustrations from his larger book with good descriptions of all stages of the insects and excellent biological notes. All the illustrations and the greater part of the letterpress are the original work of the

author. This has many advantages but some drawbacks, as, for example, a rather sweepingly exact statement that in *Erebia epiphron* "The larval stage lasts 288 days".

References are made to variation, protective coloration and migration, sufficient at least to excite the interest, and, as one would expect from Mr Frohawk, there is an excellent account of the relation of the larva of *L arion* to ants Only one misstatement has been noticed, and that not about a truly British insect, contrary to what is said on pp 38 and 41, the Monarch butterfly has an adult life up to about ten months and has a definite period of semi-hibernation in the southern United States

The classification and Latin names are the most up-to-date possible, that of the Royal Entomological Society's recent list, but the author shows either misapprehension or unbounded optimism where he refers to this as an "established International Rule" and a "permanent International Classification", we wish that it were so! Among the English names we wonder if he is trying to introduce the law of priority when he replaces the well-known 'Gatekeeper' by the older 'Hedge Brown'

On the whole an excellent book, particularly for the young naturalist in whom the desire for collecting can be replaced by wider biological interests

C B W.

Structural Geology with Special Reference to Economic Deposits By Bohuslav Stočes and Charles Henry White. Pp xv+460. (London. Macmillan and Co, Ltd, 1935.) 25s net

THE mining geologist who has a sound knowledge of the various types of crustal deformations and of the form, extent and position of mineral deposits of economic importance with their relationships to the host rocks, is well-equipped for one of the most important aspects of his work, and whilst experience in the field will always remain the best training ground, it is essential that he should be familiar with structural types of various kinds, particularly those encountered in certain mining areas in different parts of the world.

Hitherto, the mining geologist has been handicapped by the lack of a suitable treatise, for although it is true that a number of books on structural geology have been published, few of these appeal strongly to mining engineers and mining geologists, who prefer clear illustrations of dislocations and deformations as revealed by undergound mining, to long and involved descriptions of structural types which are largely hypothetical and based only on surface indications. Dr. Stočes, professor of geology at the National School of Mines of Czechoslovakia, whose former work on this subject was published in both Czech and German, and Dr. White, who has had practical experience as a consulting mining geologist in many countries since his retirement from the professorship of mining and metallurgy at Harvard University, have rendered conspicuous service to mining engineers and mining geologists by the publication of this authoritative volume. It differs from other books on structural geology in at least three important aspects it is written specially for graduate and post-graduate students of applied geology, the reading matter has been wisely subordinated to remarkably clear and well-selected sketches, diagrams and photographs, numbering in all 663, almost two to every page, and the illustrations include a large number of the structural types encountered in mining areas in different parts of the world

W R JONES

Inorganic and Theoretical Chemistry By Dr F Sherwood Taylor Third edition. Pp xiv+832+19 plates (London. William Heinemann, Ltd, 1935) 12s. 6d. net

THE third edition of this book is only 14 pages longer than the first edition, but includes sections on most of the recent developments, such as *ortho-* and *para-*hydrogen, heavy hydrogen, neutrons and positrons, atomic transmutation and artificial radio-elements The current view, that the nucleus is composed of protons and neutrons, is mentioned, but it is not adopted in the figure illustrating the isotopes of neon

Certain weaknesses, which have persisted from the first edition, still call for comment Thus, although a clear distinction is drawn between covalent and electrovalent links, salts are still occasionally formulated as covalent molecules, as when a fictitious ring-structure is assigned to barium peroxide (p 600). Conversely, an ionic structure is incorrectly assigned to hydrogen bromide (p 208), which is surely only ionised in presence of a 'base' or proton-acceptor. The student is also frequently misled by equations in which protons are shown instead of oxonium ions, as in the dissociation of water (p. 137), of acids (p. 186) and of hydrogen sulphide (p. 620) There is also a curious contradiction between the definition of a base (p 186) and a subsequent statement that substances such as ammonia are "incorrectly called bases" (p 194). These features, however, are only of minor importance in a book the merits of which have already been described in an earlier review (NATURE, 129, 919, June 25, 1932)

Technical Gas Analysis. By Dr George Lunge. Revised and rewritten by Dr H. R Ambler Pp. xvi+416. (London and Edinburgh: Gurney and Jackson, 1934) 21s net.

LUNGE'S book has held the field during twenty years, so that the new edition is overdue. The book has been largely rewritten, it aims at being comprehensive of all processes and types of method, as well as giving detailed working descriptions of the more noteworthy

Gas analysis increases in importance as more industrial operations are brought under scientific control, the degree of accuracy required varying according to circumstances: time is often an important factor. Continuous recording instruments are coming into use when possible The book follows well-known lines, and is illustrated by diagrammatic drawings of the apparatus. It should find a place in all technical and analytical laboratories.

Reclamation of the Pontine Marshes*

By DR ROBERTO ALMAGIÀ, University of Rome

THE Pontine region (in Latin, *Ager Pometinus*, from the name of the ancient Volscian city of Sessa Pometia), known more commonly in the past as the Pontine Marshes, is situated in the southern part of Latium, and has been famous from remote times During recent years, the attention of the civilised world has been directed to it, owing to the extensive reclamation works which have completely transformed its traditional aspect

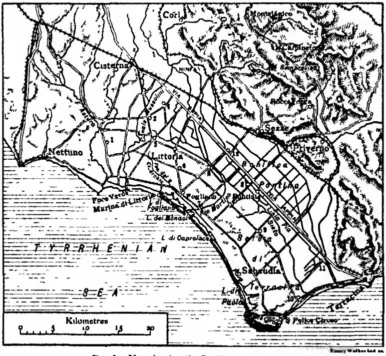

FIG 1 Map showing the Pontine region in 1933.

1	Borgo Bainsizza	7	Borgo Grappa
2	Borgo Podgora	8	Borgo Pasubio
3	Borgo Piave	9	Borgo Vodice
4	Borgo Carso	10	Borgo Montenero
5	Borgo S Michele	11	Borgo Hermada
6	Borgo Isonzo	12	Borgo Faiti

The region lies to the south of the volcanic Latium Hills and occupies the space between the Lepine Mountains—a range composed essentially, like the Central Apennines, of secondary limestones and hence of Carsic structure, and about 1,500 metres high (Monte Semprevisa, 1,536 metres)—and the Tyrrhenian Sea Close to the sea is the isolated Monte Circeo, with a structure analogous to that of the Lepines Towards the end of the tertiary and the beginning of the quaternary periods, the whole territory, with an area of about 750 sq. kilometres, must have been still, as regards its greater part, a shallow marine gulf, Monte Circeo being then an island Later in the quaternary period it became transformed into a lagoon, as a result of upheavals, which were more pronounced near the sea than at the foot of the Lepines Hence the greatest depth of the lagoon was in the interior and followed a line roughly parallel to the mountains Alternating subsidences and upheavals doubtless took place afterwards, the natural appearance of the region being repeatedly changed during prehistoric ages and perhaps also during historic times Climatic variations, affecting the flow of the water-courses and the humidity of the whole region, also came into play To-day the rainfall is less than 800 mm in the coastal district, increasing to about 1 metre at the base of the Lepines and to still more on their slopes

Without going in detail into the characteristics of the Pontine region, it may be pointed out that this may be divided into three parts·

(1) *The coastal region*, which extends from Nettuno to Terracina This is characterised by long chains of dunes of recent origin, 20 metres or more in height and more or less fixed by vegetation The dunes separate the sea from long, narrow coastal lakes, the Lake of Fogliano, the most northern, having an area of 4 65 sq km and that of Paola, the most southern, an area of 3 9 sq km; in between come the smaller lakes of Caprolace and Monaci These lakes probably represent ancient creeks, which have become separated from the sea by the formation of the dunes The two larger, exhibiting indentations on their internal shores, communicated with the sea through breaks in the line of dunes, but such breaks sometimes became filled in and so acted only intermittently Moreover, being subject to seasonal changes of level, the lakes were surrounded by stretches of marsh As will be indicated presently, work is in progress which will stabilise their configuration.

(2) *The region adjacent to the lakes* inland stands somewhat higher—20–25 metres and sometimes

* Translated from the Italian.

40 metres—and consists of sand, often of a chalky nature According to some geologists, this region represents a series of cemented quaternary dunes, which were hitherto the undisputed domain of the Mediterranean scrub and of tall forests, with only limited clear areas

(3) *The true internal region*, lying between the preceding and the foot of the Lepines, constitutes the marsh proper and corresponds approximately with the deepest part of the ancient lagoon The hydrographical conditions of this region were very irregular and variable Abundant Carsic springs at the base of the Lepines—such as those of Ninfa—fed comparatively large water-courses, the natural flow of which was hindered by the slight slope of the ground, by the chain of dunes, by the vegetation, etc

The soil varies in character throughout the region, being rich in humus and fertile in the lowest parts, where it is mixed with detritus of volcanic origin, mostly clayey and marly in the higher areas, and sandy and hence little suited to farming near the sea The region is said to have been well cultivated and thickly populated in the Volscian age (twenty-four inhabited centres are spoken of, the largest being Pometia) The destruction of the Volscian State and its subjection to Rome, together with the abandonment of the drainage schemes, in which the Volscians must have been highly expert, and possibly also climatic changes, resulted in desolation. Actually, however, there is little exact knowledge of the conditions of the region in the pre-Roman epoch, but in early Roman times the marshy areas must have been very extensive Attempts at reclamation date back to the end of the Roman Republic. Others were made during the Empire, in the Middle Ages by enterprising pontiffs like Martin the Fifth, and in modern times, under Leo the Tenth, Sixtus the Fifth and Urban the Eighth, who made appeal to the experience of Dutch engineers The most impressive endeavour was that made at the end of the eighteenth century on the initiative of Pius the Sixth, but the main drainage canal, constructed over a length of about 30 km parallel to the Appian Way, and fed by lateral channels, proved inadequate to drain the whole of the marshy area. This area, including land boggy only at times, amounted to 370 sq km. Napoleon caused the problem to be studied again by well-known hydraulic engineers, such as Fossombroni, but failed to find time to give effect to the projects elaborated

It is not possible to give here the history of the successive efforts made in the nineteenth century or of the earlier ones of the present century, which, like the splendid work of Pius the Sixth, led only to a partial and temporary solution. The more the problem was studied, the more complex it appeared The drainage question was, indeed, the first, but not the only one, demanding solution, as it led naturally to the sanitary problem—the struggle against malaria and the creation of the conditions for healthy existence There was also the agrarian problem, comprising preparation of the soil for its immediate utilisation, population and colonisation, and installation of roads and other means of communication All these issues required simultaneous resolution, and this was the aim of the law of Integral Reclamation (*Bonifica integrale*), which concerned Italy as a whole, but

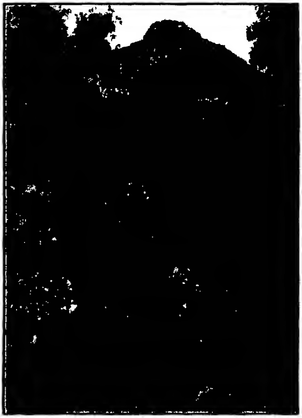

FIG 2 Mount Circeo and scrub country

found in this region its greatest and most complete application The whole of the work involved was entrusted to the Opera Nazionale dei Combattenti

The drainage problem was met by creating three systems of canals, which partly utilised existing water-courses The waters of the more northern portion of the plain flowing from the Lepine Mountains—the so-called *high waters*—were conveyed to the sea by a direct route, mainly by an extensive collecting canal (the Mussolini Canal), which is 27 km long and is the most important drainage work yet accomplished This is able to deal with a flow of 450 cubic metres per second and flows, under suitable control, into the River Astura *The middle waters* flow into another

large collector and pass to the sea through old water-courses, the principal of these being the Martino River (the work of Pope Martin the Fifth) and its tributaries the Cicerchian and Nocchian 'ditches', which have been re-organised *The low waters* flow partly into the Pia water-course, which is still in good order, and partly are collected by a network of channels and led to the Fiume Sisto (named after Pope Sixtus the Fifth), the bed of which has been widened and deepened In all, 1,756 km of canal have been excavated and renovated Other work has resulted in the drainage

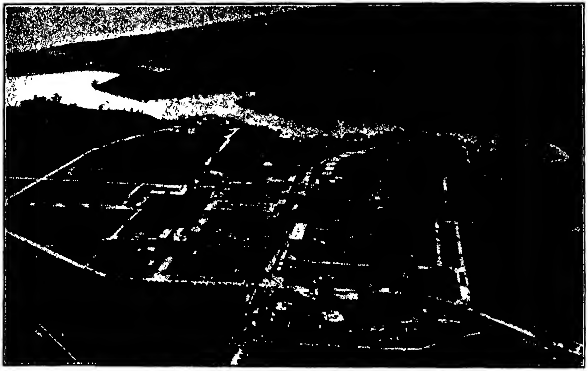

FIG 3 The new city of Sabaudia

of many wells and stagnant pools throughout the scrub zone—the so-called *Piscine* Operations on a still larger scale are in progress with the object of keeping the coastal lakes within definite bounds A number of difficult technical problems are here involved Work on Lake Fogliano, which is well stocked with fish, is already well advanced; its bed is being deepened, its banks made up and the marshy margins dried, and permanent connexion with the sea is being established. Development of Lake Paola and of the district of Sabaudia on its shore is likewise proceeding. Work on the two smaller intermediate lakes is also under way; in the case of Lake Caprolace, certain areas around it are below sea-level, and have needed special means for drainage.

The reclaimed lands were not as a rule ready for immediate cultivation. In most cases deep tilling and manuring, particularly with phosphates, have been necessary Great difficulty has been encountered in the destruction of the thick Mediterranean scrub, consisting of deep-rooted trees, and both fire and dynamite have been employed to get rid of the roots For tilling, use has been made of powerful multiple ploughs of the Fowler type The so-called Terracina Forest, containing most of the tall trees, has been preserved for inclusion in a national park, which takes in also part of Monte Circeo.

The whole plan of reclamation outlined above was, as already mentioned, put into the hands of the Opera Nazionale dei Combattenti at the end of 1931. The average daily number of workmen employed was 13,500, board and lodging being provided for them by the creation of two large villages, as well as a number of smaller settlements

During the first year—to October 1932—10,500 hectares were reclaimed and made ready for cultivation, in the second 14,100 and in the third about 17,000 The total agricultural land thus made available by the end of 1934 exceeded 41,500 hectares. In addition to the actual ploughing, etc., this necessitated the construction of houses and other buildings for the new colonies, and the creation of a network of roads, etc so as to render the region fitted for permanent occupation.

All this has involved revolutionary changes.

since, until a few years ago, the Pontine region had no stable population The section of coast from Nettuno to Terracina was, perhaps, one of the longest tracts of desert coast in the whole peninsula A few hamlets (*casali*) existed along the Appian Way, and two or three in the remaining territory. From remote times the region had had a transitory population engaged in wood-cutting, production of charcoal, and raising cattle, sheep and pigs This population lived in the most primitive huts, which contained only a single apartment and had a small, low door, with no other opening The contents consisted of a hearth built of a few stones, beds, and a few essential articles of furniture. Such huts were found especially in the forest clearings (*lestre*), sometimes in groups of three or five or more, and occasionally in villages with a hundred or more inhabitants This population came from the villages of sub-Apennine Latium (Filettino, Trevi, Veroli, Alatri, etc) and spent eight or nine months in the region (October–June).

The huts have now almost entirely disappeared, and separate farmhouses, of two or three different types, are being built at regular intervals in the newly reclaimed area As is natural in an agricultural district, the populace is a scattered one On an average, 10–12 hectares of land, with house, are allotted to each family, the area being increased twofold on the poorer soils Each farmhouse comprises living rooms, with stables below for the larger cattle Small accessory buildings contain a furnace and accommodation for pigs and chickens, and a well and drinking troughs for the cattle are also supplied, together with implements, chemical fertilisers, etc. After a certain period of tenancy, the farms will pass into the possession of their occupiers. During the first three years, ending with the year 1934, about 2,450 farmsteads were built, the colonisation proceeding from north to south and from the coastal districts inland

At certain points, chosen for ease of access, centres known as boroughs (bearing the names of battle-sites) have been instituted. Of these boroughs (*borghi*), which include a bureau of agricultural control, a health station, sometimes a school, a church, etc., twelve had been formed by the end of the year 1934. In view, however, of the vast extent of the area colonised, more important urban centres were also required to provide public services, business establishments, hotels, hospitals, places of entertainment, etc. The first of these, Littoria, was commenced on June 30, 1932, on the site of the former Quadrato, and was inaugurated on December 18 of the same year. The second, Sabaudia, situated in a magnificent position on the inner shore of Lake Paola, was begun on August 5, 1933, and officially opened on April 15, 1934 In October 1934, the first stone was laid of the third urban centre, Pontinia, in the farthest inland and lowest region, near the Appian Way, and in a zone where the work of reclamation has only just been begun ; this was to be ready for occupation in April, 1935 Two further urban centres, Ausonia and Aprilia, are already projected

Population of the agricultural districts of the Pontine region has been accompanied by that of the coasts, where seaside resorts have been developed. Among those already built are Foce Verde—to serve the Cisterna country—and Littoria Under construction is Sabaudia Beach, which will be connected with the main centre by a bridge over Lake Paola at its narrowest point During the past summer a seaside colony entertained 400 children from the families of the farmers of the Pontine region

As regards the population of this region, it should be pointed out that the occupants of the new settlements are derived, not from the district that formerly supplied its temporary inhabitants, but from distant, over-populated parts of Italy · Friuli, Vicentino, Polesine, Ferrarese, etc Admission to the colonies has been rigorously controlled, preference being given to the families of ex-service men and, among these, to the more numerous

Whereas, in the past, the Pontine region had only a single road for wheeled traffic—the old Appian Way—and a few tracks and bye-ways, the whole of the colonised portion is now traversed by a fine network of roads (416 km up to the end of 1934), adequate to meet the requirements of the new conditions and arranged according to a predetermined plan

The mainstay of agriculture is corn, which has cropped well during the first three seasons in the Littoria district Tree-fruit is also being grown and, in the south, horticultural produce—notably tomatoes, in the district between Terracina and Circeo The lower slopes of Circeo and the environs of Terracina have been noted from ancient times for their vines Beet-growing has commenced and the installation of a sugar factory at Littoria is projected. Attention will, however, probably be devoted mainly to corn, of which Italy is greatly in need.

The profound transformation brought about in Southern Latium by the Pontine reclamation is felt also in adjacent districts, especially in the Lepine towns, the relations of which with the plain below date from the earliest times The new condition of things has also had an important consequence from the administrative point of view, as it has determined the creation of a new province—the ninety-third in Italy—which

embraces a vast region reaching, towards the south, to the River Garigliano and having Littoria as its capital

The new province of Littoria has an area of 2,100 3 sq km and a population now approaching 200,000 The capital, Littoria, is a city constituted almost exclusively of offices, business houses, places of assembly, scholastic establishments, hospitals and the like, etc Its fixed population is only 2,500, but, like Sabaudia, it has been planned with a view to extensive development in the future

To Sir Charles Vernon Boys on his Eightieth Birthday

Why does Sir C V Boys elect
To do the things we least expect,
And always choose a task that seems
More suited to the land of dreams
A problem other men would shirk,
Yet solve the task, and make it work
By means that *no one* else employs ?
The answer is Boys will be Boys !

What made him buy an Otto bike—
Two wheels abreast—a thing to strike
Terror in any rider's soul,
Yet somehow manage to control
Its actions and avoid a spill,
And using his uncanny skill -
Delight in a precarious poise ?
Again we say Boys will be Boys

Why snatch a bullet in its flight,
Lit by a single spark so bright
That on a photographic plate
The fleeting shadow seemed to wait—
With wake and bow-wave primly set -
All posing for their silhouette—
And leave a picture of the *noise* ?
Because, of course, Boys will be Boys !

Why did his bold, untrammelled thoughts
Conceive the scheme of fusing quartz,
Using an arrow, as it fled,
To draw a microscopic thread,
And from the fusion to "unreel"
A gossamer more true than steel,
Which every Physicist enjoys ?
The fact is this Boys will be Boys

What made our friend so seeming rash
As to pursue a lightning flash
By lenses rapidly revolved,
And even get the problem solved -
Both of its speed and structure—by
A photograph "which cannot lie" ?
That gave a thrill that never cloys,
And showed us still, Boys will be Boys

To weigh the earth—to check the Therm -
Explain the logarithmic term—
To build with bubbles, and maintain
The opal colours in their train !
These are his pleasures, these his ploys
(Where skill with mind and Truth allows)
For which, in Science, as in Toys,
We thank our stars, Boys *will* be Boys !

R A S P

Obituary

Sir George Cory

SIR GEORGE CORY, who died on May 7 at seventy-two years of age, had spent forty-four years of his life in South Africa He received his scientific training at King's College, Cambridge, where he took honours in the Natural Sciences Tripos in 1888 After holding various academic appointments in the schools of Grahamstown, which is in the Eastern Province of Cape Colony, he was appointed professor of chemistry in Rhodes University College in 1904, and occupied the chair with great distinction until his retirement with the title of professor emeritus in 1925

Cory was undoubtedly a good teacher and was beloved both by his colleagues and his students, whom he could, and did, inspire with his own enthusiasm Indeed, some of his men have done extraordinarily well, but the truth is that though his heart was in his work, his real interest in life lay elsewhere As a consequence of this, no scientific discoveries of any great value can be placed to his credit He had neither the temperament nor the vision for chemical or physical research, and as Rhodes College was off the beaten track, there were no chemical souls with whom he could commune

Cory was really an antiquary Very soon after his arrival at Grahamstown, where much of the early South African history was enacted, he realised, as indeed did others, that records of the doings of the 1820 settlers and of others would soon be lost if an attempt was not made to collect them While others talked, Cory acted He never took a holiday, but spent all his spare time in trudging over the country covering great distances, enduring much physical discomfort, to carry on his self-imposed task All interested in South Africa know that his "Rise of South Africa", in six volumes, was practically completed some little time ago For his work in this and in other but similar directions, Cambridge awarded him the honorary degree of D.Litt. in 1921 and when he was knighted in 1922 he came to England which he had not seen for more than thirty years and did further historical research. He was awarded the gold medal of the Royal Empire Society in 1933.

MR. W R BUTTERFIELD

THE town of Hastings has suffered a grievous loss through the death of its museum curator and librarian William Ruskin Butterfield came from Bradford in 1894 as a school teacher, and soon began to take a prominent part in the work of local scientific societies as a field naturalist In 1905 he was appointed curator of the museum in the Brassey Institute, Hastings, and in 1909 librarian of its reference library, both of which under his care grew greatly in importance as centres for the study of the natural history, archæology and arts of south east Sussex In 1929 the mansion of John's Place was purchased by the town as a home for the museum This gave Butterfield his opportunity. In its new quarters under his skilful hands the museum became a live thing, each room the sanctuary of a particular science or art Meanwhile, the reference library was rehoused in the old museum, and a lending library and reading rooms were added The whole was a wonderful achievement for a man constitutionally unable to delegate responsibility, but a breakdown in health followed. From this, Butterfield recovered sufficiently to set up as an annexe to the museum the "Indian Durbar Hall" (from the Colonial and Indian Exhibition of 1886) which had been given to the town by the late Lord Brassey, and to arrange in it with his old skill the collections of "The Voyage of the Sunbeam", but he never regained complete health and died suddenly on March 24 at the age of sixty-two years

Butterfield was a great Nature lover and an accurate observer, and he contributed papers to the *Museums Journal*, of which he was for a time editor, and to local scientific periodicals His knowledge of the locality embraced not only his favourite subjects of birds and insects, but also every branch of natural history and archæology This first-hand knowledge made him an excellent expositor, whether in the museum or on Nature rambles, and many hundreds of townsfolk must owe their first interest in science to his inspiration T S D

WE regret to announce the following deaths

Sir Robert Blair, education officer of the London County Council in 1904-24, on June 10, aged seventy-six years

Mr J T Cunningham, lecturer in zoology in Queen Mary (East London) College in 1917 26, on June 5, aged seventy-six years

Mr Daniel Nicol Dunlop, O B E, a director of the British Electrical and Allied Manufacturers' Association, and a founder of the World Power Conference, on May 30, aged sixty seven years

Prof R M Holman, associate professor of botany in the University of California, an authority on the longevity and germination of pollen, and author of well known botanical textbooks, on April 23, aged forty-nine years

Prof Alice Werner, C B E, emeritus professor of Swahili and the Bantu languages in the University of London, on June 9, aged seventy-five years

News and Views

The Actonian Prize of the Royal Institution

THE Managers of the Royal Institution have awarded the Actonian Prize for 1935, of one hundred guineas, to Mr W T Astbury, for his papers on "X-ray Studies of the Structure of Hair, Wool and Related Fibres" The Prize is awarded septennially, and is given, in the quaint phrasing of the deed of trust of the Acton Endowment, to the "author of the best essay illustrative of the wisdom and beneficence of the Almighty in such department of science as the said Committee of Managers for the time being of the said Institution shall in their discretion select" It is provided that the award may be made in respect of essays or papers already published Mr Astbury was for some years an assistant in the Davy Faraday Research Laboratory of the Royal Institution, working with Sir William Bragg on various problems in connexion with the X-ray analysis of crystal structure He left the Laboratory in 1928, and is now lecturer in textile physics and director of the Textile Physics Research Laboratory of the University of Leeds. He has applied the X-ray technique acquired during his earlier work to textile problems, and the Actonian Prize is awarded to him in respect of the two valuable papers, under the general title given above, published in the *Philosophical Transactions of the Royal Society*.

Dewar Research Fellowship

THE bequest by Lady Dewar of a sum of money for the furtherance of research in the Royal Institution, in memory of the work of her husband, the late Sir James Dewar has already been announced The Managers of the Royal Institution have resolved, as the best method of giving effect to Lady Dewar's wishes, to establish a Dewar Research Fellowship, and conditions governing the award of the Fellowship have now been drawn up The research must be carried on at the Royal Institution, in a branch of science at the discretion of the Managers The appointment, which is open to persons of either sex, will be for a period of three years in the first instance, with a possible extension to five, and will carry with it a salary of £400 a year It is hoped to appoint the first Dewar fellow later this year, and applications are being invited through the usual channels

Award to Sir Frederick Banting

THE Society of Apothecaries of London at a Court Dinner held in Apothecaries' Hall at Blackfriars on June 4 conferred upon the discoverer of insulin, Sir Frederick Banting, the Society's Gold Medal in Therapeutics, the highest honour which the Apothecaries' Company can bestow After the presentation, Sir Frederick thanked the Society on behalf of those

who were associated with the early work on insulin, and referred to the desire of Canadians to be in touch with 'the old land' He said that, as professor of medical research in the University of Toronto, he saw research students passing away from the University, in one year forty-five per cent of the graduates of the University went to the United States; nevertheless their bond with the British Empire was stronger than with America, their desire was to become more British He asked that Canadian students should be made kindly welcome in Britain in order that their sentiments of kinship might be made stronger In Canada they are endeavouring to send their students to Britain, for the great thing about British medicine is that it rests on a solid foundation Traditions are only beginning in Canada, in this respect there is a great difference from Britain The Canadian who comes over here takes back with him on his return some of the high traditions which guide men in Great Britain The bonds of fellowship are stronger and more enduring than financial inducements, which are a source of weakness Sir Frederick's great wish is that the ties with Britain should be strengthened

The Quetta Earthquake

FEW details of scientific interest have as yet reached England from the Quetta district Shocks of course continue to be felt, some of them strong enough to bring down walls left standing among the ruins The destruction of Quetta City is almost complete Landmarks of all kinds have disappeared, and the city is a widespread mass of debris An official report gives the number of killed in it as 26,000 out of a population of 40,000 In addition to the towns of Kalat and Mastung, at least one hundred villages have been totally destroyed within a band 130 miles long and 20 miles wide, the number of killed in them being estimated as between 12,000 and 15,000, so that the total number of deaths is probably about 40,000 So impossible is it to excavate the dead bodies in Quetta City that all the survivors have been removed in fear of an outbreak of disease. The city has been surrounded by barbed-wire entanglements and will be protected by guards in order to save the property of survivors from marauding tribesmen, it is intended that the city shall remain so sealed for a whole year

International Co-operation in Americanist Studies

AN important proposal for the promotion of studies in American ethnology and colonial history on an international basis is to be submitted to the next General Assembly of the League of Nations It originated with M. Levillier, delegate of the Argentine, who proposed to the last General Assembly that arrangements should be made for the publication by international co-operation of a series of original and authoritative works dealing with the indigenous peoples and cultures of the Americas and with the history of the discovery, geographical exploration, conquest, settlement and colonial government of the continent in the sixteenth century. The proposal was approved in principle and referred to the International Institute of Intellectual Co-operation for consideration and report on the organisation and financial arrangements necessary to give it effect Such a scheme has now been prepared by a committee of Americanists appointed by the International Institute. The Committee is a strong body of distinguished diplomatists and historians, but as much stress is laid on the importance of the ethnology of America and the history of indigenous cultures, it is a little surprising to find that anthropology is represented on the Committee by one member only Although that member, M Paul Rivet, is a host in himself, it might, perhaps, have been expected that some, at least, of the numerous distinguished authorities on American ethnology and culture would have been included in the list of those consulted by correspondence, where Prof Stolyhwo of Warsaw appears as the only anthropologist

THE suggestions of the Committee provide for the publication of, approximately, fourteen volumes dealing with indigenous ethnology and culture, and fifty dealing with the historical side of Americanist studies These volumes would be published over a period of years at the rate of, say, four a year, two in ethnology and two in history. In a comprehensive and detailed synopsis of topics, the subject-matter has been classified into six sections, of which the first covers the geology and natural history of America and the archæology, physical anthropology, demography and culture of the Indians The remaining five sections cover European relations with America before and after the Spanish discovery, the history of the discovery and exploration of the various parts of the continent, the conquest, the colonial period and administrative, social, religious and economic organisation during the sixteenth and down to the beginning of the seventeenth century from all points of view The preparation of the volumes, which will appear in English or French, and will be in the nature both of monographs on specific points of research and treatises of a synoptic and general character, will be entrusted to scholars of admitted and international repute The general aim of the Committee in preparing the scheme has been to promote the better mutual understanding of the peoples of the Americas and Europe and at the same time to remove popular misconceptions as to the methods and aims of the conquistadores and early colonists While the Committee is unable to suggest precisely the price at which volumes should be published, as this must vary according to the amount of illustration, it mentions as an approximate figure 60 francs, with a subscription price of 40 francs, and invites advanced promises to subscribe in order to facilitate consideration of its proposals

Origin of Man Again

AT the Victoria Institute or Philosophical Society of Great Britain, on March 25, Mr. Douglas Dewar read a paper entitled "A Critical Examination of the supposed Fossil Links between Man and the Lower Animals". The paper contains no critical examination

of any of the fossils, but it shows how expert opinion has differed regarding the interpretation of the relationships of the relatively few specimens which have been found. The interpretation of fragmentary fossils is a ticklish business (witness the controversy regarding the significance of the Caithness fossil *Palæospondylus*, notwithstanding that scores of complete specimens are known), so that no one need be unduly disturbed by different interpretations of anthropoid fragments. Nevertheless, Mr Dewar correctly sums up the position when he states that "science can truthfully say that it knows not when, where or how, man originated", but he understates the truth when he says that this is all that science knows, for although there is "no conclusive evidence that any Primate genus has been transformed into any other genus", there are resemblances in detail and gradings which require much explanation if transformism is to be rejected To say that "each new type appears in the rocks having all its characteristics, as if it had migrated from some other locality", simply pushes the problem back to the 'other locality' How did it originate there?

Special Creation or Evolution?

MR. DEWAR does not say so, but probably he would agree with the view of the president of the Victoria Institute, Sir Ambrose Fleming, that man and every other genus began as a special creation In support of that thesis, Sir Ambrose regards the Java, Heidelberg, Piltdown and Pekin 'men', as biological abnormalities, passing over the probabilities against the disappearance of all the normal forms of their time, and the preservation of abnormalities only He holds that "if nearly as many [human] individuals die as are born in a year, there can be no particular contest for food and one of the factors in the Darwinian causes of evolution is thereby removed" ("Modern Anthropology *versus* Biblical Statements on Human Origin". Second edition. London. Victoria Institute, 1935 1*s*) But this mortality rate is what actually happens in every stable species of plant and animal, and the enormous destruction has generally been regarded as affording just that opportunity for selection which Darwin postulated These and other aspects of the anti-Darwin controversy are dealt with in a lively booklet by Sir Arthur Keith, "Darwinism and its Critics" (The Forum Series, No. 20 Pp. vii+56 London. Watts and Co., 1935 Paper, 7*d*. net, cloth, 1*s* net), in which he defends the theory of evolution against the arguments of Sir Ambrose Fleming, and of other critics, some obviously ill-informed as to the facts. Sir Arthur clings to his hard-hitting style, but his punches are clean, and he swings a good knock-out. Also he adheres to the adage of a recent school grammar book—"explain clearly, as if to a Scotsman . . ."

London Television Station

THE Postmaster-General announces that the Television Advisory Committee has recommended the adoption of the Alexandra Palace for the London Television Station. This recommendation has been approved by the Postmaster-General, and the British Broadcasting Corporation has made arrangements with the Alexandra Palace trustees for the use of a portion of the buildings for the station The ground at the Alexandra Palace is 306 ft above sea-level, and it is proposed to erect a 300 ft mast on the site, thus providing an aerial height of 606 ft above sea-level which, it is considered, should enable a high definition television service to be provided for the London area The Baird Television Company and the Marconi-E M I Television Company are being invited to tender for the supply of the necessary apparatus for the operation of their respective systems at the station The Baird Company proposes the adoption of a standard of picture definition of 240 lines sequential scanning, 25 picture traversals a second, 25 complete frames a second, and the Marconi-E M I Company propose a standard of 405 lines, 25 pictures a second, interlaced to give 50 frames a second, each of 202½ lines The Committee proposes that the vision signals shall be radiated on a wave-length of about 6 6 metres and the associated sound signals on a wave length of about 7 2 metres

Television in Germany

A REGULAR television transmission service has already been inaugurated in Berlin by the German Post Office authorities, and arrangements are made whereby the public can attend demonstrations so that they may see for themselves what the new service has to offer An article describing the proposals for the further development of television in Germany was given in the *Wireless World* of May 24, as an abstract of a paper by W Scholz, recently published in *Elektrische Nachrichten Technik* The television transmissions are of the 180 line, 25 pictures per second type and are given on ultra-short waves of less than 8 metres Both sound and vision transmissions take place on these wave-lengths, so that a single heterodyne oscillator may be used at the receiver for both portions of the programme A total band-width of 2,400 kilocycles per second is allocated to each station for the combined programmes In the scheme proposed, it is assumed that a minimum field-strength of 1 millivolt per metre has to be provided, and that the transmitters will have aerial powers of from 2 to 20 kilowatts on wave-lengths between 5 7 and 7·5 metres The lower-power stations will be erected on mountain peaks at heights ranging up to 4,000 ft, and it is estimated that the effective range of these stations will be of the order of 85 miles On this basis, it is considered that the whole of Germany can be provided with a television service by means of twenty to thirty stations, the wave-lengths being distributed geographically so as to avoid mutual interference.

Progress in the Gas Industry

THE seventy-second annual general meeting of the Institution of Gas Engineers was held in London on June 4–7 under the presidency of Mr. C. Valon Bennett of Rochester. He reviewed the present

position and general trends in the industry as a supplier of solid, liquid and gaseous fuels There is a movement for gas works to pass into the control of holding companies, a process which has led at times to increased efficiency and a reduction in prices to the consumer Mr Bennett indicated the dangers to be feared where undertakings were bought at inflated prices, owing to the availability of cheap money, and where the motive force was financial opportunism irrespective of public good In some countries, organisations have been established for the official testing and certification of gas appliances Mr S Lacey and Mr C A Masterman contended that such a movement could bring no advantage in Great Britain, where the safety and efficiency of gas apparatus already exceeds that current in other countries Mr W L Boon described the rapid advance of gas coke in public favour for domestic purposes. The development of the gravity feed boiler has resulted in coke displacing oil firing of central heating installations With these boilers, uniform conditions can be maintained automatically, with attendance once in 24 hours, at a very low fuel cost Open coke grates are increasing in popularity and already some 70,000 have been installed in London alone

Flock of Birds Mistaken for Sea-Serpent

LIEUT A. J. COBHAM, R N, sends us an account of a flock of low-flying birds being mistaken for a sea-serpent Similar observations have been made before, but it is worth while to put Lieut Cobham's notes on record On March 14, 1935, H.M.S *Electra* was 100 miles S W of C Spartel (North Africa) At about 17 30 G.M T, weather being fine and visibility a maximum, Lieut. Cobham was on the bridge with a midshipman and a signalman Suddenly to the westward, about 200 yards off, what seemed to be a sea-serpent was seen, travelling at about 30 knots on a slightly divergent course. "It had a small head, on the surface, creating a bow-wave, and behind, at intervals of approximately 12 feet, there were four humps, each with a bow-wave Every 20 seconds or so the beast submerged for a few moments. Inspection with binoculars showed the phenomenon to be a flock of small birds of the guillemot family (*Alle alle* or *Fratercula arctica*). They were flying in five 'V'-formations, skimming so closely over the water that from time to time they were hidden by a swell. The light, due to a heat haze, was peculiar The sea, to the westward, appeared to be an oily grey colour, against which the birds showed black All three of us had the same impression on sighting, and so 'real' was the appearance that after establishing the truth with binoculars, the birds still looked exactly like a sea-serpent when seen with the naked eye"

Avon Biological Research

THE annual report of the biological research which is being carried out on the River Avon at Southampton in association with the University College there gives an account of the varied lines of work pursued in the second year of this scheme (Southampton. University College 2*s* 6*d*). The general condition of the coarse fish in the area is described, with a special note on the incidence of 'black spot' disease among them Methods are being sought for checking the loss of fish in mill-races, in the flooding of water-meadows, and by poisoning from decaying masses of weed The use of green light has been tried to deter fish from entering dangerous waters, as well as a revolving fish screen which automatically keeps itself free from debris Preliminary experiments have been made on the hatching and rearing of salmon and trout under natural and artificial conditions, and the resulting yield and condition of young fish were determined The work was seriously hampered throughout by the drought conditions of 1933-34

National Institute of Agricultural Botany

THE fifteenth annual report (1933-34) of the National Institute of Agricultural Botany, Cambridge, shows that continued progress has been made in all departments An important change in the stations at which crop testing is carried out took place in the autumn of 1934, when a new centre was established at Askham Bryan near York, in place of that at Good Easter, Essex, which was closed down The results at the latter station had proved so similar to those at Cambridge, that it seemed more valuable to extend the Institute's activities in a northward direction. Two new winter wheats from the Cambridge University Plant Breeding Institute were tested (162/8/1*E*, and W 70 *A*) and gave very promising results, while 'Resistance', the new winter oat which had proved so outstanding in former trials, was put on the market for distribution Continued progress is recorded in the work of the Official Seed Testing Station, 29,487 samples being dealt with during the year under review. With regard to the activities of the Potato Testing Station at Ormskirk, eighty-seven entries were received for the official immunity trials, and all but three of these remained free from wart disease in the field It is noteworthy that, with the exception of three varieties known to be duplicated, all the new varieties entered for the trials proved to be distinct. This is a striking tribute to the way in which the Potato Synonym Committee has been able to check the practice of distributing old varieties under new names and at an enhanced price

Report of the Development Commissioners

THE twenty-fourth report (1933-34) of the Development Commissioners which has just been published (London: H.M. Stationery Office. 2*s*. net) deals mainly with the various purposes for which advances from the fund were made to assist agriculture, rural economy and fisheries. In general, the allocation of grants was very similar to that in the previous year, but although no actual payments were made, arrangements were completed whereby the work at certain British institutes, hitherto financed by the Empire Marketing Board, could be continued.

Since detailed descriptions of the scientific work in progress at the various research institutes aided by the Development Fund are published elsewhere, only a brief outline of their work is given in the present report. The scheme, organised by the Society of Friends, for assisting unemployed men in cultivating allotments, was once again given financial support, in view of the great success of the work in 1933. Disappointment, however, is expressed that it was not possible to assist as many as had been hoped, chiefly owing to the difficulty in securing suitable land. The Rural Economy Section reports progress on nearly all sides, and rural industries are being developed over most of Great Britain on practical and profitable lines. Fishery research has also produced valuable results, particularly with regard to the herring and haddock industries. The determination of the best-sized mesh to use to ensure that undersized fish are not landed has enabled definite legal regulations to be enacted, and the survey of young haddock stock has rendered it possible to forecast the quantities of marketable fish and their probable distribution in future years. The report concludes with a financial statement and a schedule of the grants allocated during the year under review.

Agricultural Research in East Africa

THE Colonial Office has issued the sixth annual report (1933-34) of the East African Research Station at Amani (London: H M Stationery Office 1s net), from which it is evident that progress has again been made in all the various research activities with which the Station is concerned. As regards coffee investigations, the earlier impression that heavy applications of organic manures to *arabica* coffee effectively offsets the harmful influence of soil acidity has now been confirmed, while culture solution studies suggest a marked correlation between acidity of the medium and the degree of branching of the roots which occurs, high acidity being associated with an unbranched type of root system. Results of importance have also been obtained by the plant pathology section, as the vector of the mosaic disease of *Cassava* has been definitely proved to be a species of white fly (*Aleurodidæ*). On the biochemical side comes the discovery that the fermentation of coffee is an unnecessary process so far as quality is concerned, though the difficulties of correlating quality with the method of preparation of the coffee are still not overcome. The cultivation of sisal (*Agave amaniensis*) continues to increase, and the first lot of seedlings raised at the research station are now becoming available for fibre tests, the standardisation of which has been considerably developed during the past year.

Fishery Research in the U.S.S.R.

THE organisation of fishery research in the U.S.S.R. is the subject of a brief but highly important article by Prof. B. S. Ilyin in the current issue of the *Journal du Conseil* (9, No. 3. Conseil Permanent International pour l'Exploration de la Mer. Andr. Fred Høst et Fils, Copenhague. December 1934). The Scientific Institute of Marine Fisheries, formerly the Central Scientific Institute of Fisheries (Moscow), and the State Institute of Oceanography (Moscow) have been united under the name of the "Union Scientific Institute of Marine Fisheries and Oceanography". The new Institute is designed to function as a planning, guiding and co-ordinating centre for the activities of the numerous fishery stations situated around the coasts of the U.S.S.R. Its purpose is to promote the welfare of the fisheries by acquiring data concerning marine biological and oceanographical phenomena, and intelligently applying the results. In this connexion the formation of an economic section is of especial interest and importance in view of present events and tendencies in the fishing industry of Great Britain. The Institute will issue three series of publications—*Transactions*, *Records* and *Bulletins*—all in Russian, but the first two will be furnished with English, French or German summaries. The address of the Institute is Moscow, Vorkhne Krasnoselskaya 17.

Research in the Electrical Industry

THE fourteenth annual report of the British Electrical and Allied Industries Research Association (the E.R.A.) shows that the electrical industry is fully alive to the commercial value of research. It has been well supported both by the Government and the various branches of the industry during last year, and although we do not agree that there can never be a point "at which research has all the support it needs and deserves", it has certainly not been "oversubscribed" in the past. The long list of researches the Association has before it, still inadequately financed, shows that there is need for further co-operative help. It is interesting to read that designers of insulating material for electrical material are now attaching less importance to a knowledge of the electric strength of their materials and more to their thermal conductivity. The importance of Fourier's theorems on the conduction of heat is being fully recognised, and also that temperature is a leading factor in electrical breakdowns. For some years the flame of the Méker burner has been the standard for the determination of "resistance to naked flame". It has been found that the standardisation of the burner flame in conjunction with simple correction factors is unsatisfactory, as flame temperature is not correlated to the calorific value of the gas in a simple manner. Further experiments are being made to develop a standard flame for scientific tests in connexion with 'inflammability'. The electrical resistivity map of the soil of England and southern Scotland has now been completed, and a summary of the work done on telephone interference has been published. Tests on radio interference are in progress. A list is given of the Government departments, engineering and scientific institutions, universities and colleges which have co-operated in the work of the Association.

Progress in Radio Communication

A paper by Col. A. S. Angwin giving a review of the progress of radio communication for the year

1934 (*J Inst Elec Eng*, Feb. 1935) is of general interest. The great technical progress made in broadcasting during the last two years is reflected in its rapid development At the beginning of 1932, the number of licensed listeners in Europe was nearly 14 millions, and two years later it was nearly 20 millions In 1929 the total power used in broadcasting was 420 kilowatts, whilst two years later it was more than ten times greater Now that an average high-power station consumes 2 million electric units a year, it is important to use only transmitters of high efficiency The extended use of short-wave telegraph working in ships has enabled the British P O stations to communicate regularly with whaling boats in the antarctic and in eastern waters Directive aerials have been erected at these stations covering all the main shipping routes of the world, and this has greatly improved the services Additional radio-telephone services from Great Britain to South Africa, Egypt and India have been opened up, while services to Japan, Shanghai, Kenya and Iceland are projected By extension to circuits already existing, radio communication is now possible with nearly all the South American States The outstanding feature in radio research has been the intensive study with the help of the cathode ray oscillograph of the propagation of waves in the ionosphere. The methods now in use indicate that the reflected signal resulting from a single pulse incident on the ionosphere consists frequently of a doublet the components of which are separated by a small time-interval The reflected components are apparently electrically polarised waves of opposite rotational sense

Machine Mining and Labour Problems

ALTHOUGH machine mining has made comparatively rapid progress during recent years, there is still room for a great advance in mechanisation In a paper by Mr J Dooley, printed in the *Mining Electrical Engineer* of February, it is stated that in Yorkshire, which is one of the most progressive coal fields of Great Britain, only about one third of the coal produced is cut by machines and only about a sixth is loaded on to conveyor belts. There are a few coal seams from which coal simply rolls over into the 'tub', and it would be quite unnecessary to 'machine-cut' the faces of these seams But even in these cases mechanical loading could be economically applied by means of conveyors of suitable design. Another economic factor which has to be taken into account is the possibility of a shortage of suitable labour in the near future. This question may rapidly become acute as newer and more attractive industries and interests arise to attract the boys and young men who would otherwise automatically enter the pits. It is true that to some extent machines displace labour temporarily, yet the position may be reversed, and collieries be compelled to put in machines because sufficient labour is not available. It is essential for colliery managers to get to work with new ideas, and arrange and organise systems of work so that full advantage be taken of the existing types of machinery. There are machines already in use designed to carry enormous loads in supporting the roof and protecting other machines employed for cutting, loading and conveying coal simultaneously American collieries have very large outputs per 'man shift', far in advance of anything ever attempted in Great Britain

Pacific Science Association

THE Fifth Pacific Science Congress of the Pacific Science Association was held in Canada in 1933 under the presidency of Dr H M. Tory, president of the National Research Council of Canada. The Congress, which was held under the auspices of the National Research Council of Canada and through the generosity of the Government of Canada, was a notable achievement in the history of the Association Representatives of no less than thirty-two countries attended the Congress, while the total number taking part in the meetings exceeded four hundred The meetings were held in Victoria, B C, on June 1-4 and in Vancouver, B C, on June 5-14. The success of the Congress has now been crowned by the publication of the *Proceedings* in five large volumes amounting to more than four thousand pages (Toronto: University of Toronto Press, London. Oxford University Press, 1934 5 vols 84*s* net) These volumes form a noteworthy summary of scientific knowledge from many aspects contributed by research workers of those countries bordering the Pacific Ocean It is clearly not possible to review the contents of these volumes, but mention should be made of the lavish hospitality extended to the members and participants by the Canadian authorities The many social functions and the interesting excursions arranged for the entertainment of the visitors must have largely fulfilled one of the main objects of the Pacific Science Association, which is "to strengthen the bonds of peace among Pacific peoples by promoting a feeling of brotherhood among the scientists of all the Pacific countries" This alone should be sufficient tribute to the devoted care and energy given by those responsible for the organisation of the Congress

German Science

A NEW quarterly review in English of German science has appeared under the title "Research and Progress" (Terramare Office, Berlin W 8), the editor being Dr. Karl Kerkhof. In the second number, which appeared in April, the articles are mostly geographical or cultural and historical in character Prof Erich von Drygalski discusses the effect of the polar regions on the history of the earth, dealing with the influence of currents of air from the pole from the physical, biological and human points of view, while Prof Rudolf Spitaler considers the influence of shifts in the earth's axis on the production of earthquakes. Prof. Diedrich Westermann deals with a subject on which he has already made his views familiar to English readers—the changing African. The introduction of syphilis from the New World in 1493 is characterised by Prof. K. Sudhoff as a legend; it is suggested, however, that it may have spread by earlier contacts between the Old

World and the New through eastern Asia No reference is made to recent research, which seems to point to its existence in Europe in early prehistoric times The cults and ritual of myth are discussed in two articles, one by Prof K Th Preuss on the significance of birth and death and their relation to initiation and other forms of ceremonial in which sex is an element, and the second by Prof Gustav Hubener, who regards the position of the hero in early epics as based upon his power as an exorcist. Although this does not exhaust the list of contents, mention can be made here of one other paper only—Prof Erich Haenisch's interesting suggestion that the vertical arrangement in Chinese writing is due to the form of the ancestral tablet The papers are brief, running to two or three pages only, and the treatment summary and popular As a counter to English comment on Germany's 'purge', it does not make a really impressive showing

Studies of the Rarer Elements

IN his address as retiring president to the Chemical Society given on March 28 and entitled "Recent Researches on Certain of the Rarer Elements" (*J. Chem. Soc*, p 554, April 1935), Prof G T Morgan outlined some of the most important advances which have been made in recent years in the study of the rarer elements The British Empire is endowed with mineral resources to an extent unsurpassed by those of any other nation It is obviously the duty of British chemists to undertake the systematic investigation of the rarer elements of the Empire, for it is certain that results of inestimable value will be forthcoming. Prof Morgan is himself an outstanding leader in this kind of work and the results which he and his colleagues have accumulated form the main topic of the address The extraction of germanium and gallium from Northumberland coal-ash has been started by Dr. G. R Davies Certain seams of Northumbrian coal give an ash containing up to 1 per cent of germanium and 0·05 per cent of gallium The germanium is distilled out with acid as tetrachloride, whilst gallium trichloride remains in the still. A diagram of the apparatus is given. Rhenium has been extracted from Australian molybdenite by a lengthy process involving fractional volatilisation and ultimate separation with organic reagents such as 8-hydroxyquinoline and dipyridyl The address concludes with some notes on the co-ordination compounds of ruthenium, amongst which is an ammine which dyes natural silk in red shades but is extremely difficult to isolate in a state of purity.

A Central Statistical Institute

DESPITE the immense increase in the amount of statistical material which has become available during recent years, investigators still lack the data for even approximate measurement of many of the most important economic forces. In an article in *World Survey* of May 1935 entitled "The Case for Economic Measurement", Mr G D. H. Cole pleads for the establishment of a Central Statistical Institute in Great Britain which would undertake the regular and prompt compilation and issue of this type of information, including regular surveys of production, prices, wholesale and retail trade, population movements and the like He also advocates the publication of an annual "Progress of Britain Report" like that issued by the Government of India The annual "Statistical Abstracts of the United Kingdom", it is true, go back nearly to the middle of the nineteenth century, and though greatly improved since the early issues, they have by no means been expanded in proportion to the development of the official *corpus* of statistics taken as a whole, and anyone who wants to collect the bare essentials of the current statistics in Great Britain has to work through much scattered material in numerous official publications Mr Cole also states that the publications of the Stationery Office on the subject are often expensive; while in most towns it is impossible to find any place where even the most important public documents can be consulted, and for private students or even small institutions, the cost of buying the bare minimum of requisite reports is excessive

Prices of Biological Books in 1934

THE analysis of the cost of biological books in 1934, by John R Miner (*Quart Rev Biol*, Dec 1934, p 496), illustrates the significance of the devaluation of the dollar in affecting relative prices of American and foreign books. The estimates of cost are worked out in cents per page, the price of a foreign book being converted at the current rate of exchange, and the total number of pages upon which the calculations are based is 123,876 The only country in which prices have fallen is U S A where (at 0·93 cents a page) there has been a drop of almost 9 per cent compared with 1933 prices British Government publications have dropped from 1 39 to 0 89 cents a page and are now the cheapest of the lot apart from U S Government publications, which are issued at the amazingly low price of 0 18 cents a page; but the British Government sample was too small to be reliable British books, on the other hand, have risen in terms of dollars by 45 5 per cent, French by 35 and German by 32 As to relative prices, British books now slightly exceed in price American books (0·96 against 0 93), France stands at 1 00 and Germany at 1 89 cents a page As was noted in the report for 1933, the high prices of German scientific books and periodicals have proved a hardship to libraries and individual workers, and although as the result of a conference with German publishers some reductions in the prices of scientific periodicals have been made, evidently these reductions do not extend to scientific books

Books on Horticulture

MESSRS. WHELDON AND WESLEY, LTD, of 2, 3 and 4 Arthur Street, New Oxford Street, London, W C.2, have rendered a valuable service to gardeners by compiling a "Comprehensive List of Books on all Branches of Modern Horticulture, and a Selection of the Early Literature" (New Series, No 39, 1935).

More than 1,000 titles are included in the forty-four pages of the pamphlet, and they cover every aspect of gardening, both practical and scientific. The section on early literature contains eighty-seven numbers, and includes the rare "Niewe Herball" by Dodoens, the first English edition of which was published in 1578. Sections on soils, manures, diseases, pests and propagation introduce the garden reader to well-chosen books on these subjects, whilst volumes describing vegetables, fruit, greenhouse produce, cacti, alpines, orchids, roses and other flowers are amply represented, as well as works on garden design and general practice.

The Green Flash

A NOTE in NATURE of May 25, page 866, gave a number of references to observations of the green flash and the conditions producing the phenomenon. In connexion with this subject, Dr Raymond M. Bell, of the Pennsylvania State College, directs attention to Admiral Byrd's account of the phenomenon in the *National Geographic Magazine* (58, 186, 1930). Admiral Byrd observed the green colour for as long as thirty five minutes in Antarctica as the sun rolled along the horizon.

Announcements

A REUNION dinner of former students of the University of Leipzig will be held in London on November 2; further particulars will be announced later. Those who desire to attend should send their names either to Prof. W. Wilson, F.R.S., Bedford College, London, or to Prof. F. J. Wilson, Royal Technical College, Glasgow, as soon as possible, but not later than October 1.

THE International Congress on Malaria which was to have been held at Madrid next October has been postponed to the spring of 1936.

A SOCIETY OF EUGENICS has recently been founded at Bucharest under the presidency of Prof. G. Marinesco, professor of nervous diseases and electrotherapy in the University.

AN international radio station for the distribution of medical consultations to ships of every nation on the high seas has been founded at Rome with the Marchese Marconi as president of honour.

THE autumn meeting of the Iron and Steel Institute will be held in Manchester on September 16–18. Further information can be obtained from the Secretary, The Iron and Steel Institute, 28 Victoria Street, London, S.W.1.

THE tenth international congress of the history of medicine will be held in Madrid under the presidency of Prof. G. Marañon on September 23–29, when the following will be the principal subjects for discussion: Arabian medicine in Spain, medicine in America during its discovery and colonisation; medical folklore in various civilised countries. The subscription is 75 pesetas each for members of the International Society of the History of Medicine and 100 pesetas for others. Further information can be obtained from the Secretariat of the Congress, Arrieta 12, Madrid.

AT the eighteenth annual meeting of the American Society of Ichthyologists and Herpetologists held at the Carnegie Museum, Pittsburgh, Pa., on May 2–4, the following officers were elected for the ensuing year: *President*, Clifford H. Pope, American Museum of Natural History; *Vice-Presidents*, Henry W. Fowler, Philadelphia Academy of Natural Sciences, Tracy I. Storer, University of California, E. H. Taylor, University of Kansas; *Secretary*, M. Graham Netting, Carnegie Museum; *Treasurer*, A. W. Henn, Carnegie Museum; *Editors*, Carl L. Hubbs and Helen T. Gaige, Museum of Zoology.

A GENERAL discussion on "Phenomena of Polymerisation and Condensation" has been arranged by the Faraday Society to be held in Cambridge, on September 26–28. The following workers from outside Great Britain have promised contributions and hope to be present: Dr. H. J. de Boer (Eindhoven); Dr. R. Houwink (Eindhoven), Prof. J. R. Katz (Amsterdam), Dr. O. Kratky (Vienna), Prof. H. Mark (Vienna), Dr. J. C. Patrick (Yardville, U.S.A.), Dr. G. Salomon (Zurich), Prof. R. Singer (Berne), Prof. H. Staudinger (Freiburg-im-Breisgau), Prof. H. I. Waterman (Delft), Dr. H. B. Weiser (Houston, U.S.A.), Prof. G. S. Whitby (Ottawa). It is also hoped that Prof. A. Favorskij (Leningrad), Prof. F. Medrodjev (Moscow), Prof. K. H. Meyer (Geneva) and Dr. W. Carothers (Wilmington, U.S.A.) will be present. Further details can be obtained from the Secretary, Faraday Society, 13 South Square, Gray's Inn, London, W.C.1.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A junior assistant, a research investigator and a junior research investigator to the British Non-Ferrous Metals Research Association—The Secretary, Regnart Buildings, Euston Street, N.W.1 (June 17). A lecturer in bacteriology in the University of Birmingham—The Secretary (June 22). A civilian educational officer in the Royal Air Force Educational Service (engineering or physics)—The Secretary (A.E.), Air Ministry, Adastral House, Kingsway, London, W.C.2 (June 24). NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 1002.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Passage of Helium through Compact Solids

IN NATURE of January 5, p. 30, experiments were described showing that gelatine, celluloid and cellophane, like vitreous silica, will allow helium (but not air) to pass fairly freely through them at the ordinary temperature. I have since found that vitreous boron trioxide has the same property. Vitreous borax, like the common glasses, does not possess it.

As regards the behaviour of single crystals, I have tried a number of them, and have failed to prove the passage of helium at the ordinary temperature through any. The provisional positive result with a beryl crystal before reported has proved to be erroneous, and is withdrawn.

Experiments on crystals at a higher temperature are in hand. The known facts about the extraction of helium from minerals by heat suggest that a positive result is likely.

Isotopic Constitution of Platinum and Rhodium

THE analysis of the platinum ions from a high-frequency spark[1], using a new spectrograph, shows that this element consists of five isotopes with masses 192, 194, 195, 196, 198. The middle three form a triplet of almost equal strength, while the heaviest is decidedly weaker and the lightest very faint.

In the new spectrograph, the ions are deflected through 90° in a cylindrical condenser and are then further deflected through 180° by a magnetic field. The distances and radii of curvature are arranged so as to bring a divergent bundle of ions with small differences in their energies to a focus at the centre of the photographic plate. With a slit 0.1 mm. wide, images of about the same width were obtained, giving a resolving power of 1 in 1,000. Using an alloy of platinum with 10 per cent rhodium as electrodes of the spark, the isotopes of platinum were widely separated, and the doubly charged platinum ions could be compared directly with the rhodium isotope at 103, previously observed by Dr. Aston. No companion to the latter could be found even though the main line was much over-exposed. From its position we would expect platinum to have very nearly integral masses. On this assumption the average of six photographs gave an atomic weight of $102 \cdot 92 \pm 0 \cdot 03$ for rhodium, in approximate agreement with the chemical atomic weight.

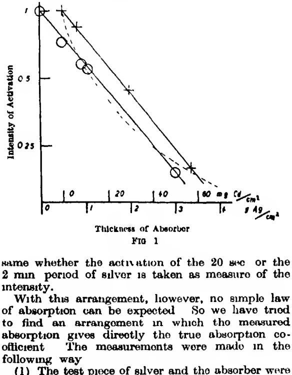
Absorption of Slow Neutrons

FERMI and others[1] have shown that slow neutrons are very strongly absorbed by various elements; they found that the absorption curves are by no means exponential. The arrangement used in their experiments was to put the flat test-piece between sheets of the absorber inside a hole in the paraffin block that contained the source. Experiments that we have made under similar conditions have led to the same result, the absorption observed being the



Thickness of Absorber
FIG. 1.

same whether the activation of the 20 sec. or the 2 min. period of silver is taken as measure of the intensity.

With this arrangement, however, no simple law of absorption can be expected. So we have tried to find an arrangement in which the measured absorption gives directly the true absorption coefficient. The measurements were made in the following way.

(1) The test piece of silver and the absorber were placed outside the paraffin block containing the source, which consisted of 150 mC. radium emanation mixed with beryllium. If the test piece is put inside a hole in the paraffin, a neutron which has already crossed the test piece once can be scattered back again so as to return to the test piece, so that the effective thickness of the absorber becomes greater than the measured value. In our arrangement no neutron can reach the test piece a second time after having passed through it once.

(2) The paraffin block was shaped so that there was no wax in the direct path (about 20 cm.) between the source and the test piece; the activation produced by fast neutrons could therefore be allowed for, by subtracting the activity produced in the absence of paraffin.

(3) The absorbers consisted of hollow spheres or cylinders so large compared with the test piece in the centre that those neutrons which reach the test piece must traverse the absorber nearly normally.

The absorption of cadmium and silver was measured The logarithms of the measured intensities are plotted in Fig. 1, against the thickness of absorber. The absorption is in both cases exponential so far as the observations extend, that is, down to one fifth of the original intensity. The half values are 1 25gm /cm [2] for Ag and 24 mgm /cm [2] for Cd Fermi's values for cadmium are given as the dotted line in Fig 1

This result, that slow neutrons are absorbed exponentially under suitable experimental conditions, suggests either that the active neutrons are of fairly homogeneous speed or that, in the region of velocity of the neutrons concerned, the nuclear cross section does not depend appreciably on the velocity of the neutrons

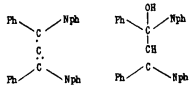
Experimental Demonstration of the Allene Asymmetry

WE have succeeded in verifying the prediction made by van't Hoff in 1875, but hitherto unverified, that unsymmetrically substituted allenes,

would be found to exhibit enantiomorphism

The difficulty in demonstrating the association of optical activity with this structural type lay chiefly in the synthesis of a substituted allene with suitable salt-forming groups This difficulty can be avoided by the employment of asymmetric catalysis, and we have by this means obtained diphenyl di α-naphthyl allene (I)



I II

in optically active forms (It has long been recognised that the dissymmetry of van't Hoff's type persists when *a* is identical with *c* and *b* with *d*)

The different forms of the allene were obtained by dehydration of the alcohol (II). The inactive form, produced by ordinary methods of dehydration, melts at 242°–244°. When the dehydration is carried out catalytically by heating with *d*-camphorsulphonic acid in benzene solution, there is produced, together with the inactive form, a certain proportion of a powerfully dextrorotatory isomeride with $[\alpha]_{5461}$ + 437° This optically active modification is much more soluble than the inactive allene and can be isolated in well-formed crystals melting at 158°–159°. When *l*-camphorsulphonic acid is used as the catalyst the corresponding lævorotatory enantiomorph with $[\alpha]_{5461}$ – 438° is formed

It was shown that these optically active isomerides of m p 158°–159° were actually enantiomorphous forms of the allene by mixing their saturated solutions at the ordinary temperature, when the inactive (racemic) allene of m.p. 242°–244° crystallised

The active forms have very considerable optical stability, though they gradually lose their activity when heated above 160°.

The Straight Chain- and the Many Membered CH_2 Ring-Molecule

THE heats of combustion of a CH_2 group are the same in a normal and in the cyclo molecule, except the first members of the two series Almost the same holds for the refractivities if the very small differences in the cyclo series are disregarded From these two facts it must be concluded that the carbon-carbon and the carbon-hydrogen distances are the same in both series, and that the whole electronic configuration of an individual CH_2 group is nearly identical in both structures

Yet it is found that there is a marked difference in the densities or molecular volumes in the two series when these measurements are made at temperatures near the melting point This fact was first noticed and has been fully discussed by L Ruzicka and his collaborators A summary of their systematic work has recently been published in the *Journal of the Society of Chemical Industry* (January 1935)

Owing to the kindness of Prof Ruzicka, who supplied me with a number of these cyclo compounds, I was able to measure their molecular volumes by means of X-rays, the substances being in the solid state[1] In this paper I came to much the same conclusion as Ruzicka and his co-workers, and ascribed the high density of the cyclo compound as due to the strain produced by the bending of the chain into a ring

Looking into this matter since, I calculated the molecular volume of a CH_2 group both in a straight chain and in a cyclo compound, using for this calculation some earlier measurements on hydrocarbons at low temperature[2] These are the figures·

Average volume of a CH_2 group in the cyclo hydrocarbon $C_{18}H_{36}$ and in the *n* - $C_{18}H_{38}$, in 10^{-24} c c

Temp (abs)		cyclo		normal
90°	solid	23 3	solid	23 7
290°	solid	24 6	liquid	28 8
330°	liquid	27 6	liquid	30 0

($C_{18}H_{36}$ has a particularly high density in the whole series of cyclo compounds)

The striking fact is that the molecular volumes become identical at a low temperature; or in other words, the two substances differ only in their coefficient of thermal expansion This is not surprising. Although the CH_2 groups in both series are nearly the same, there must be a difference in their mobility, since one group is part of a chain with two free ends and the other group is in a closed chain which as a whole must have a higher rigidity.

An Ancestral Habit in a Sea-Urchin

THE heart-urchin *Echinocardium cordatum* is one of the most abundant species in the littoral fauna of the British Isles. It is found everywhere where smooth sandy beaches occur and it is distributed all over the bottom of the North Sea to the Danish coast. Its normal mode of life is to excavate a burrow for itself situated about 6 inches below the surface of the sand; this burrow is connected by a vertical shaft with the surface. The roof of the burrow is supported by a cockscomb-like crest of curved spines and the surface of the urchin is quite unpolluted by the sand which forms the wall of the burrow. Through the vertical shaft the urchin protrudes the long tube-feet which belong to the anterior ambulacrum; the discs terminating these tube-feet are fringed with fingers so as to resemble small sea-anemones and with these the urchin sweeps up small animals lying on the bottom. So effective are they, that where *Echinocardium* abounds no mussels can exist; for as soon as the young mussels metamorphose from free-swimming larvæ, they are seized by the tube-feet of the buried *Echinocardium* and conveyed to its mouth.

The heart-urchin is capable of deserting its burrow and moving elsewhere to dig out a fresh one; but, so far as hitherto observed, its movements are carried out by the spines of its under surface, which are curved and end in spoon-shaped tips; obviously tube-feet could give little support in shifting sand.

The habits of the regular sea-urchin form a complete contrast to those of the heart-urchin. When opportunity is afforded of seeing the regular urchin in its natural surroundings, it is easy to see that it is pre-eminently a climber. It is found clinging to vertical faces of rock; it uses its long tube-feet as cables to pull it forwards whilst it steadies itself with its spines. Gifted with sharp razor-like teeth, it gets its living by scraping the short algal growth from the rocks on which it climbs. In my opinion, this climbing habit explains the evolution of the globular sea-urchin from a flattened starfish-like ancestor.

During a recent visit to Plymouth as a member of the committee which annually inspects the biological station there, I observed a half-grown *Echinocardium cordatum* confined in a square glass tank with vertical walls. To my amazement I saw that the animal had climbed one of the vertical walls, to which it was clinging by its tube-feet, using these in the same manner as does the regular sea-urchin.

Now all the evidence available points unequivocally to the conclusion that the heart-urchins have sprung from ancestors which, did they live now, would be regarded as regular urchins, so that we find buried deeply in what we may call 'psychic constitution' of the heart-urchin an inherited habit which, in the normal circumstances of its life, can rarely if ever be called into play, but which is nevertheless there and can function if the necessity for it arrives. Truly the inner constitution of this, as of all other animals, is made up of layers of habits!

Mixed Agglutination

IF a mixed suspension of sheep erythrocytes and a certain strain of Friedlander bacilli are made to agglutinate in the presence of both homologous antisera, what appears to be a novel form of agglutination —*mixed* agglutination—is observed. The clumps obtained under our conditions by thus simultaneously mixing two antigens and their antibodies in the same system are seen to consist not only of red cells adherent to red cells, and not only of bacilli adherent to bacilli, but also of bacilli and red cells adherent to one another. Control experiments with only one antiserum do not yield the mixed clumps, although occasionally a red cell or two may be seen adherent to the specifically agglutinated organisms, and vice versa.

It is planned to carry out similar experiments on other systems composed of two or more antigens and their respective anti-sera to ascertain if this phenomenon, as yet observed only in these preliminary experiments, is a general one. If the phenomenon is a general one, and if the point of view be accepted that sensitisation involves more or less of a surface deposit of anti-body globulin, it would appear that under certain conditions the part of the globulin molecule related to its specific properties is unessential for the process of agglutination.

Mechanism of the Pasteur Effect

THE following recent observations are relevant to the aerobic glycolysis and increased oxygen uptake[1] caused by addition of potassium salts to glucolysing brain slices, and also to the mechanism of the Pasteur effect.

Potassium chloride causes increased oxygen uptake in brain tissue with substrates other than glucose, for example, fructose and lactate, which cannot form lactic acid in nitrogen. Here no aerobic glycolysis results. Further, the rate of disappearance of lactate ($-Q_L^{O_2}$) is markedly increased by potassium.

Substrate	Without M/10 KCl		With M/10 KCl	
	Q_{O_2}	$Q_L^{O_2}$	Q_{O_2}	$Q_L^{O_2}$
Fructose 0.2 per cent	−6.9 −6.5	+0.2 +0.2	−10.5 −9.2	−0.1 −0.65
Lactate 0.2 per cent	−9.2 −9.1	−1.75 −1.4	−14.05 −14.7	−5.25 −4.10

Again, potassium chloride causes aerobic glycolysis in the case of mannose[2], which can form lactic acid anaerobically.

The following theory is put forward to explain the co-existence of aerobic glycolysis and increased respiration with glucose, as well as the sparing action of oxygen on the glycolysis of normal cells. Oxygen may be supposed so to affect the cell permeability as to set a limit to the rate at which glucose can reach the cell enzymes. Inhibition of the Pasteur effect consists in a removal of this limitation, so enabling more glucose to reach the intracellular enzymes. This increased permeability results in an increased rate of both respiration and lactic acid formation.

The view that agents which inhibit the Pasteur effect do so by affecting cell permeability is readily acceptable in the case of potassium. It is an old suggestion[3] that metal ions may affect cell surfaces by converting a water-in oil emulsion to an oil-in-water emulsion. The fact that the inhibition of the Pasteur effect, brought about by potassium, is reversed by calcium is a point, on the whole, in favour of such a hypothesis; thus we found that a $Q_L^{O_2}$ of 16·5 in presence of glucose and $M/10$ potassium chloride was reduced to 2·0 by addition of $M/20$ calcium chloride, though addition of sodium chloride in the same concentration did not reverse the potassium effect. Further, we found that rubidium and cæsium had a similar effect to potassium in causing aerobic glycolysis. Values of $Q_L^{O_2}$ on the same brain in the presence of $M/10$ concentration of the chlorides of these metals were, for potassium 10·3, for rubidium 10·35 and for cæsium 5·85, while for magnesium a value of 2·9 was obtained.

In view of the present evidence, we consider that in the absence of oxygen, the permeability of the cell is so altered (see Cowan[4]) that the enzymes are completely accessible to glucose. The enzymes are saturated, and the rate of lactic acid formation becomes maximum. In the presence of oxygen the enzymes are much less accessible to the substrate. Glucose reaches the enzymes relatively slowly, and lactate is either not formed, or is formed at a slower rate than that at which it can be oxidised. If lactate be the substrate added, it too can only slowly gain access to the enzymes, and therefore its rate of removal is relatively low except when potassium is added.

Statistical Aspect of the Production of Primary Lesions by Plant Viruses

AN analogy has frequently been drawn between the production of bacterial colonies on artificial media and of primary lesions on the leaves of susceptible host plants inoculated with an extract of virus-diseased tissues. In a recent paper, Youden, Beale and Guthrie[1] have carried this analogy one step further, and have suggested that the relation between the numbers of lesions and the relative concentrations of virus particles in the inoculum may be described in the same way as the relation between the numbers of bacterial colonies and the concentration of bacteria in the plated suspension. Their equation takes the form:

$$y = N(1 - e^{-ax}),$$

where y is the number of lesions given at any concentration x of the virus, N represents the maximum lesions obtainable, and a is a constant.

There is no reason to doubt that this equation is fundamentally correct, but there is good reason to doubt whether it applies to the majority of the dilution data which they have collected from various published papers and cited in proof of agreement (Ref. 1, Table II). If the values for low dilutions are fitted by this equation, the calculated values for higher dilutions are almost uniformly too small, and sometimes, as in the following case quoted by Youden, Beale and Guthrie from a paper by Samuel and myself[2], the differences are far beyond the limits of the experimental error.

Lesions observed	12144	7470	4314	3363	2010	1003
Lesions calculated by Youden, Beale and Guthrie	11756	8572	3932	1415	467	150

The standard error of the total 1003, for example, is 79·4. Youden, Beale and Guthrie, in transcribing this series, omitted the two figures for the weakest concentrations; they are 477 and 234, and the calculated values would be approximately 48 and 15.

As proof of agreement, these authors plot values of $\log(N-y)$ against concentration and show that, in the cases they choose for the purpose of illustration, the values fall approximately on a straight line. This gives a misleading idea of the goodness of fit, as when N is much greater than y, y may vary widely without causing wide departures from a straight line. About two years ago, attempts were made to apply this equation to a series of experiments performed by Mr. Samuel and myself in which samples of crude juice from plants diseased with tobacco mosaic were diluted with distilled water. The more accurate the experiment and the wider the dilution range it covered, the more apparent it became that under our conditions the relation of lesions to concentration could not be described in these terms. For some time I have been working to find under what conditions the equation does apply, and to what departures are due; briefly, it applies only to very carefully purified suspensions of virus. Distortions exist with samples which are carried to that stage of purification where only slight pigmentation remains.

It is doubtful, therefore, what meaning can be attached to the constants calculated by Youden, Beale and Guthrie from equations that fit only portions of the dilution series; and until this has been decided the equation derived from the Poisson series should not be used for the correction of results obtained by the primary lesion method except with very carefully purified samples of viruses.

The Dyestuff Industry

I FEAR that Prof. Armstrong is very angry with me (NATURE, June 1, p. 907); for with him such phrases as "management and commercial side", "commercial community", "commercial outlook", "commercial mind" are of course terms of comprehensive opprobrium, and lie at the opposite end of the scale to such mellifluous, desirable and creditable phrases like "true technical leadership". Perhaps after all I do deserve his anger, for he says "I have more than once discussed the situation, most recently in an article in the *Pharmaceutical Journal*". As I regularly read most of what Prof. Armstrong writes,

this was not news to me, although I have not yet reached the stage when I can, just because Prof. Armstrong says so, accept it as the complete and absolute faith

It may be that I must both live and die a rebel But I do think it high time that someone might at least call a halt to this fifty years merciless (and to my mind, unfair) belabouring of the commercial man for the loss of a great and scientific industry, and it accords with poetic justice that this should be done by one who, if he cannot claim to be a chemist, cannot claim to be anything at all

However, I am not unduly alarmed because Prof Armstrong does agree with me that the pioneers *did* leave the industry, and that the industry *did* languish, and, mark you, they were captains of their own industry—in those days "the commercial and management side" had not even arrived Prof Armstrong further tells us that when they, Perkin and Nicholson, retired, "the fate of the industry was sealed already in 1865". Why? I can only gather from his letter that it was due to Perkin being 'without imaginative power" and in the case of Nicholson because *his* partners "would not move with the times"

May I hope that when Prof Armstrong reads a lecture which he did not hear, he may find that he is not in such complete disagreement "with the side represented by Mr Cronshaw—the managerial and commercial side" as a hasty pen led him to suppose

I observe that Prof. Armstrong, obviously warming to his theme, says that "History cannot be written at a distance from the events by those who have had no direct knowledge of the period considered, and of the men concerned", a dictum that would have robbed the world of a large number of its greatest historians It automatically robs chemistry of an attractive and provocative historian except for the space of four score years

In his last paragraph, Prof Armstrong has some hard words to say about the industry I fear he has not the necessary feeling for the conditions prevailing No one who is in a position to know shares his view, but this cannot be a novel situation for Prof Armstrong In one thing his letter completely persuades me that it is possible to have "direct knowledge of the period considered and of the men concerned" and still not write history However, for that we shall have to wait and see

CECIL J T CRONSHAW.

Prediction of Earthquakes

THE appalling havoc wrought by earthquakes in India during the past eighteen months has attracted wide attention to the fact that, so far, science has failed completely to devise any means of providing a warning of the imminence of such disasters. At a lecture on Indian earthquakes, given at the Royal Society of Arts in March of last year[1], this fact was deplored both by the lecturer, Sir Edwin Pascoe, and by Sir Thomas Holland, both of whom have held the position of director of the Geological Survey of India. In referring to the Bihar earthquake of January 1934, Sir Thomas Holland emphasised that "There was no warning whatever and that destruction was sudden and complete in a few minutes". The same words apply equally well to the more recent disaster of Quetta and, in fact, to most major earthquake disturbances The value of a warning, in the saving both of life and property, can scarcely be exaggerated, even if it is of a general character and comes long ahead of the actual disturbance.

As there are no reasons for supposing that this long-felt want will always lie beyond the powers of science, it is reasonable to suggest any line of approach which conceivably might lead to the desired end One of these, which apparently has never been considered, lies in the possibility that anomalous electrical potentials may arise in the ground during the building up of the stress conditions which ultimately result in an earthquake Electrokinetic phenomena may reasonably be looked for under such conditions, and if they could be detected and the resulting ground potentials proved to be measurable, then it is not unlikely that when mapped they would afford a clue as to the stress distribution in the district examined In fact, to anyone with a fertile imagination and familiar with some of the recently developed methods in the electrical branches of applied geophysics, it seems just conceivable that the position of an epicentre might be predetermined in this way Furthermore, the changes in the potential gradients with time might provide evidence as to the imminence of an earthquake disturbance

A virtue which may be claimed for this tentative suggestion is that it is one which could be tested without great difficulty and, assuming that telegraph or other land lines could be used for the measurements the expense would be relatively small Periodical measurements of the potential differences existing between points on a network of stations in an area subject to seismic disturbance might well provide information of real value

Critical Phenomena in the Oxidation and Self-Inflammation of Hydrocarbons

MESSRS NEUMANN and AIVAZOV direct attention[1] to the negative temperature coefficient of the combustion of hydrocarbon mixtures under certain conditions; this phenomenon, which has also been referred to by Pease[2] and by Beatty and Edgar[3], seems well established. The explanation given in the letter is a formal presentation of the views which have been put forward in various communications dealing with hydrocarbon combustion, the peroxide theory and knock in engines The step $A \rightarrow B$ is the normal process whereby the hydrocarbon is oxidised to aldehyde

The peroxide theory postulates that this process takes place via an intermediate peroxide which in normal circumstance may be written $RCH_3 + O_2 \xrightarrow{k_1} (RCH_3O_2) \xrightarrow{k_2} RCHO + H_2O$, but in favourable circumstances the intermediate step can give rise to chain branching and hence eventually to ignition in a lower temperature range. The conditions for maximum concentration of X or RCH_3O_2 are as indicated in Neumann and Aivazov's letter The conditions in which chain branching occurs are particularly important in connexion with the phenomena of knock; thus the presence of anti-knocks lower the effective concentration of X, while

the efficacious proknocks all seem to disrupt in such a way as to lead to a similar type of branching The mechanism whereby this branching leads to reformation of X and thus autocatalysis is discussed in a forthcoming publication

Electronic Energy Bands of Solid Copper, Nickel, Cobalt and Iron

DURING the course of experiments on the soft X-radiations of the elements copper, nickel, cobalt and iron, evidence of electronic energy bands has been obtained The examination of the radiations was made with a tangential grating vacuum spectrograph, and the lines under investigation were the group comprising the L series These, and especially the L_a line, have been obtained with considerable intensity Examination of the plates has shown a blackening on the long wave side of L_a Microphotometer records demonstrate that this is due to the fact that the line, although possessing a comparatively sharp peak, drops to zero very slowly on this side, and extends almost to the L_η line Making an allowance for the slit width of the instrument, the wave-length difference between the maximum of intensity of the line and the end of the 'tail' is, for copper, 1·21 A. This corresponds to the large energy difference of 77 5 electron volts The other three elements give energy differences somewhat less, but of the same order

The distribution in this band, namely, a fairly sharp short wave edge and a gradual diminution on the other side, suggests that the electrons in the initial state ($M_{IV, V}$) may follow, very roughly, a Fermi distribution Such an explanation has been shown to be applicable to the K_a lines of a number of the light solid elements in which the initial state contains the valence electrons[1] In the present case the $M_{IV, V}$ electrons are expected to be only partially bound, and some such distribution is therefore not altogether unexpected. It might be anticipated that the energy distribution of the $M_{IV, V}$ electrons would resemble more closely that of a semi-conductor than that of a metal, and it is therefore satisfactory to note that there is a marked similarity in shape between the present bands and that of the K_a line of graphitic carbon

Taking the value 77·5 volts as the energy-spread in a Fermi distribution, the density of $M_{IV, V}$ electrons in the metal may be calculated The result is too high, and corresponds in fact to the impossible value of 37 electrons per atom. It seems very likely that this is because the electrons are not completely free and cannot, normally, occupy the whole of the space in the lattice of the metallic crystal. Assuming that the number of electrons in the $M_{IV, V}$ group of copper is 10, one obtains the result that these are free to move in 27 per cent of the volume of the crystal

[1] Houston, *Phys Rev*, 38, 1791, 1931 O'Bryan and Skinner, *Phys. Rev*, 44, 602, 1933. 45, 370, 1934.

The Phenomenon of 'Wings' as a Vibrational Raman Effect: A Correction

WE have shown in our previous experiments[1] that the wings accompanying the primary scattered line in liquids are mostly connected not with the rotation of molecules but with slow oscillations probably characteristic of the crystal lattice, and have pointed out that this phenomenon is thus connected with quasi-crystalline structure of liquids

In our note in NATURE of March 16, 1935, an error has crept in the data and photograph given for the crystal of naphthalene do not, in fact, refer to this substance, but to the p-dibrombenzene crystal In the case of naphthalene crystal, we have observed in the region of wings four Raman lines with frequencies. $\nu_1 = 45$ cm $^{-1}$, $\nu_2 = 73$ cm $^{-1}$, $\nu_3 = 109$ cm $^{-1}$ and $\nu_4 = 124$ cm $^{-1}$

We give in the following table the oscillation frequencies in the region of wings for crystals so far examined by us In all the substances studied, the

Crystalline substance		Frequencies in cm $^{-1}$				
Benzene	C_6H_6			62	104	
p-Dibrombenzene	$C_6H_4Br_2$	20	38		93	
Diphenylether	$(C_6H_5)_2O$	22	38	67	104	
Naphthalene	$C_{10}H_8$		45	73	100	124

benzene ring is present, and this may probably explain the appearance of frequencies common to some of the crystals

We have studied the state of polarisation of new lines in the crystals of p dibrombenzene and diphenyl ether when the exciting light was unpolarised and polarised For different lines, various coefficients of depolarisation ρ were found, ranging from $\rho = 0$ to $\rho \approx 1$ For one line of p-dibrombenzene, $\nu = 20$ cm $^{-1}$, we have found $\rho \gg 1$ (in the case of polarised exciting light) Moreover, the coefficients of depolarisation for these lines depend upon the orientation of the crystal As in melting the crystal, these Raman lines broaden in a continuous spectrum around the primary line, it is not surprising that in many liquids the wings are strongly depolarised The depolarisation factor $\rho_n \to \frac{6}{7}$, which is to be expected for rotational Raman lines, found for the wings by some observers when unpolarised exciting radiation was used, can be regarded as a fortuitous coincidence

Distribution of Nuclear Mechanical Moments

TOLANSKY has suggested[1] that some importance might be attached to the relatively frequent occurrence of small values of those nuclear spins which seem to be due to neutrons, as compared with protons Even without a detailed nuclear model, an interpretation of the trend may be given

The nature of the effect of the exclusion principle on the average energy of similar particles is well known. The symmetry of states with opposite spin allows the particles to have a smaller average kinetic energy and energy of binding than they might have with parallel spins. This tendency (together with

the favour bestowed by second-order effects on the spin with the greatest number of states) seems to be effective in making even numbers of neutrons and of protons have zero moments But for protons this preference for opposite spins is opposed by the effect of the exclusion principle on the average repulsive electrostatic energy If the spins are parallel, the particles avoid very small separations, thus decreasing the average Coulomb energy Since the binding-type energy is apt to have no singularity at coincidence[2], the Coulomb energy may predominate at small separations and be relatively more important in determining spins than in questions of stability

Although the actual states of the nucleus are probably an intricate mixture of the states of a representation of single-particle quantum numbers, their energy should be affected by the same trends as determine the order of states in a simple representation If we consider a representation which includes orbital moments, the magnetic spin-orbit coupling (which is apt to be very strong, especially in heavy nuclei) introduces another tendency toward smaller moments for neutrons than for protons If the spin gyromagnetic ratio is positive for protons and negative for neutrons, as seems likely from deflection data, this tends to make spin and orbital mechanical moments parallel for protons and opposite for neutrons.

Production of Electron Pairs and the Theory of Stellar Structure

IN the discussion of problems of stellar structure, only the deviations from the perfect gas laws arising from degeneracy due to the exclusion principle for the electrons have so far been considered. In fact, as has recently been shown by one of us[1], these deviations involve far-reaching limitations on the possible stellar configurations under given conditions. Thus, it can be deduced from the form of the equation of state of a degenerate gas, taking due account of relativity, that in order that degeneracy should develop in any part of a star, the ratio β of gas pressure to total pressure at that point must satisfy the condition

$$\frac{960}{\pi^4} \cdot \frac{1-\beta}{\beta} < 1, \qquad (1)$$

and on the standard model, in which β is assumed to be constant throughout the star, this implies the existence of a critical mass

$$\mathfrak{M} = 6\ 6 \odot \mu^{-2}, \qquad (2)$$

($\odot$ denoting the mass of the sun and μ the molecular weight) above which degeneracy cannot set in at all. A study of the equilibrium of completely degenerate gas spheres leads further to the result that there is an upper limit

$$M_3 = 5\ 7 \odot \mu^{-2} \qquad (3)$$

to the masses of such configurations; this affords the possibility, for stars of mass $\leqslant M_3$, of a course of evolution leading to complete degeneracy through intermediate stages comparable to the observed white dwarf configurations

Quite another type of deviations from the perfect gas laws, however, arises from the existence of a definite distribution of positrons as well as electrons in equilibrium with temperature radiation, and in this note we desire to point out the bearing of this fact on the theory of stellar structure, and especially to indicate to what extent the conclusions summarised above have to be modified

In the first place, no effect of the latter type can take place if the electron assembly is completely degenerate, for in that case all the states of negative energy will necessarily be occupied, which on Dirac's well known picture implies the total absence of positrons For the theory of stellar structure this obvious remark has the consequence that, under white dwarf conditions, the influence of pair production on the configuration will be entirely negligible, and the possibility of evolution mentioned above, for stars of mass $\leqslant M_3$, can be upheld without modification

More generally, the presence of an equilibrium distribution of pairs in addition to the 'excess' of electrons, which is proportional to the material density, will give rise to a correction term in the equation of state, and the effect of this term on the stellar structures may conveniently be surveyed on the standard model It is found that for a fixed value of the ratio β, the correction increases with temperature, tending to a finite limit as the temperature tends to infinity When the condition (1) is fulfilled, the maximum deviation from the perfect gas law is less than 2 per cent, which means that the effect is altogether negligible for stars of mass $< \mathfrak{M}$, in which degeneracy of the electron assembly is able to occur For more massive stars, however, the correction term becomes increasingly important Thus already when $1 - \beta = 0\ 2$, corresponding on the standard model to a mass of $12\ 6 \odot \mu^{-2}$, the maximum effect amounts to 7 per cent For very massive stars, say, of mass greater than $30 \odot \mu^{-2}$, equilibrium configurations analogous to the white dwarf configurations for masses $< M_3$—but differing from the white dwarfs in that the deviations from the perfect gas laws now arise from the production of pairs and not from degeneracy—are therefore formally possible, and the question suggests itself Do such configurations exist in Nature ?

A detailed derivation of the results here summarised is to be published elsewhere

Formation of Mercury Molecules

IT has long been known that mercury vapour is ionised by photons having energies considerably less than that corresponding to the ionisation potential of the mercury atom Rouse and Giddings[1] showed in 1926 that mercury vapour is ionised by its resonance radiation, 2537 A To explain this effect, Houtermans[2] suggested that an excited atom in the 2^3P_1 state of 4 9 volts energy may combine with a metastable atom in the 2^3P_0 state of 4·7 volts energy to

form an ionised molecule and a free electron The energy available for ionisation of this molecule is (4 9 + 4 7) volts plus the heat of dissociation of the neutral molecule, which Winans[3] gives from band spectra data as 0 15 volt, making a total energy of 9 75 volts

The existence of mercury vapour molecules has never been demonstrated So far as chemical evidence is concerned, the ratio of the specific heats and vapour density determinations all show that mercury vapour is strictly monatomic Nevertheless, the occurrence of bands in the absorption and emission spectra of mercury vapour demand the presence of molecules

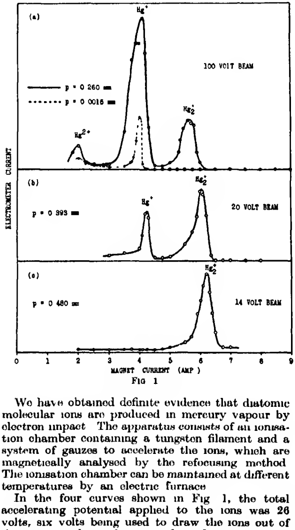

FIG 1

We have obtained definite evidence that diatomic molecular ions are produced in mercury vapour by electron impact The apparatus consists of an ionisation chamber containing a tungsten filament and a system of gauzes to accelerate the ions, which are magnetically analysed by the refocusing method The ionisation chamber can be maintained at different temperatures by an electric furnace

In the four curves shown in Fig 1, the total accelerating potential applied to the ions was 26 volts, six volts being used to draw the ions out of the region where they are formed, and another twenty volts to accelerate them into the analyser The broken curve in Fig 1 (*a*) shows the result obtained when the pressure of mercury vapour was 0·0016 mm of mercury The curve shows the presence of Hg^+ and Hg^{2+} ions, but no trace of a molecular ion. The continuous curve in Fig 1 (*a*) shows the result obtained for a pressure of 0·26 mm. of mercury. In addition to the atomic ions, there now appears a strong peak of Hg_2^+ ions The energy of the electrons producing ionisation was 100 volts for both curves. Fig 1 (*b*) shows the result obtained when the energy of the electrons was reduced to 20 volts, and Fig. 1 (*c*) for a beam of 14 volts. The curves are not drawn to the same ordinate scale

We see that as the energy of the electron beam decreases, the ratio of molecular to atomic ions increases, until at 14 volts the probability of atomic ionisation is so small that the atomic ion peak does not appear The fact that the molecular ion peak is still quite strong provides evidence for the theory that the molecular ions are formed by mutual attachment of two excited atoms or of an excited atom with a normal atom Measurements of the variation in height of the molecular peak with pressure indicate that it varies with the square of the pressure, which supports the above theory

This theory of the formation of the molecules clearly reconciles the chemical evidence of their non-existence with the band spectra evidence of their presence, for, unless the atoms are excited by light or electron impact, the vapour may remain monatomic This would require the neutral unexcited molecule to be unstable

Work is in progress to determine the variation with electron energy of the probability of formation of the molecular ion, and an investigation of the nature of the ion formed by irradiating the vapour with the resonance line 2537 A is also being undertaken A full account of these experiments will be published shortly

A Simple Method of Heterochromatic Photometry

As is well known, it is difficult to compare the intensities of lights of different colour We can tell when one is much brighter or much darker than the other, but values obtained for the point of balance by the direct methods differ widely amongst themselves It is consequently necessary to use the flicker photometer or the step-by-step method, in the latter method a series of lights of different colours intermediate between the colours to be compared is used, and the one end colour is compared with the first of these, the first with the second, the second with the third and so on Thus by reducing the difference in colour its disturbing effect is eliminated at the expense of some time and a cumulative error in the settings

I have found that lights of different colour can be compared easily by the ordinary Rumford or shadow photometer, if the rod is replaced by a partially transparent strip of glass. The method is most easily understood by the description of a particular case

A green inside-colour-sprayed 40-watt Osram lamp was compared with an 8 c.p. carbon lamp The matt glass screen of the photometer was at 0 cm. on the bench and the 8 c p. lamp at 380 cm. As rod I used first of all a strip of black paper mounted on a plate of clear glass, then a strip of fogged photographic film mounted on a similar plate, and finally a lighter strip of film mounted on another plate The two films transmitted respectively about $\frac{1}{16}$ and $\frac{1}{4}$ of the light incident on them. With the opaque strip the one shadow was green and the other orange; with the dark film, owing to the colours mixing, the

difference in the colours of the shadows was not so pronounced, and with the light film it was less still

The same observer then made ten settings with the opaque strip, ten settings with the dark film, and ten settings with the light film The mean position of the green lamp was found to be at 162 2 cm, 169 9 cm, and 171 1 cm in the three cases, the probable errors of the means being 3 5, 1 6 and 2 9 cm respectively Thus the dark film gave the most accurate and the opaque strip the least accurate results It is obvious that for each pair of lights there must be a most favourable density for the film, for if it were perfectly transparent, there would be no shadows

It would be interesting to compare the accuracy of this method with that of the step by-step method, but the comparison should be made by someone practised in the routine of the latter method

Preparation of Colloidal Metals

IN the course of an investigation of the properties of thin dielectrics at high field strengths, an interesting phenomenon has been observed, involving the passage of substances through the dielectric, and leading to a method for the preparation of colloidal suspensions of liquid metals and alloys in semi conducting media

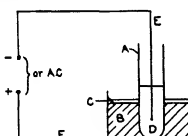

FIG 1 Diagram of apparatus for preparation of colloidal metals *A*, cellulose acetate cup, *B*, mercury bath, *C* and *D*, tricresylphosphate, *E* and *F*, metallic electrodes

Referring to the diagram, if a cup-shaped semi-permeable membrane (for example, 0 1 mm thick), prepared from cellulose acetate and containing a semi-conducting liquid such as tricresylphosphate, is immersed in a bath of mercury, then an electric field of the order of 40 kv/mm. applied between the mercury and the tricresylphosphate will cause a copious flow of mercury through the cellulose acetate, the mercury remaining colloidally dispersed in the tricresylphosphate Either alternating or continuous voltages may be used, but in the latter case the polarity must be as shown. The mercury is covered with a thin layer of the semi-conducting medium, which serves to wet the surface of the cup as the latter is lowered into the mercury The suspensions made by this means have remained stable for considerable periods.

Influence of an Electric Field on the Thermal Conductivity of a Solid

A SUBSTANCE with a permanent electric moment, such as bees-wax, was allowed to solidify in an electric field Afterwards it showed permanent greater thermal conductivity in the direction of the field, which had been applied before solidification occurred, than when it solidified without an electric field When an alternating field (50 cycles) was applied during the solidification, no alteration of thermal conductivity was noticed

Cryolysis, Diffusion and Size of Particles

PROCEEDING from earlier considerations[1], the view was put forward recently that under the effect of freezing[2], particles of aqueous solutions of lyophilic biocolloids will undergo disaggregation or aggregation according to the prevailing concentration of the particles

To test the validity of this conclusion, further experiments were carried out with the object of determining the speed of diffusion of frozen (at −17° and −79° C) and unfrozen solutions of sodium oleate, ovalbumin and polyacrylic acid Under our experimental conditions and with these substances, it could be shown that the effect of freezing causes in solutions of concentrations up to 1 per cent a disaggregation which could be measured by an increased speed of diffusion, and in solutions of concentrations higher than 1 5 per cent an aggregation manifesting itself by a decreased speed of diffusion in comparison with that of the unfrozen solutions There was only one exception observed This occurred in experiments carried out with freshly prepared solutions of polyacrylic acid, due to the fact that this substrate swells before it undergoes solution The more the concentration is diminished, the more the disaggregation prevails, and the more the concentration is increased, the more we can observe an aggregation which may lead up to a coagulation

These observations may afford further support to explanations given elsewhere for the transient increase in activity of frozen solutions of zymases, peroxidases and tyrosinase in connexion with the carrier theory[3] of enzymatic activity, may also explain the well-known effect of increased fertility of soil after a severe winter period, and may also have some bearing on the explanation of the behaviour of certain lyophobic colloids during the freezing of muscle plasma

Details of these experiments will be published shortly elsewhere

Products of Hydrolysis of Glycogen

ATTEMPTS in this laboratory to repeat the isolation of a trisaccharide from the products of hydrolysis of glycogen by glycerol extracts of muscle, as described by Barbour[1], have been unsuccessful, this is in agreement with the results recently reported by Carruthers[2]

In confirmation of Barbour's results, however, it was found possible to obtain a hydrolytic product with a reducing power equivalent to 30-33 per cent of the glycogen disappearing, and to obtain therefrom a phenyl osazone similar in crystalline form to that described by Barbour. Nevertheless, attempts at purification of the products of hydrolysis according to the methods described by Barbour were uniformly unsuccessful, and in view of similar negative results reported by Carruthers, investigation of this trisaccharide appears to merit further consideration

Points from Foregoing Letters

LORD RAYLEIGH reports that vitreous boron trioxide, like vitreous silica, allows helium to pass through it Single crystals do not allow the passage of helium, and the report of a previous positive result with beryl crystal is now withdrawn

Using a new mass spectrograph and ions from a vacuum spark, Prof A J Dempster finds that platinum consists of five isotopes and that rhodium is single

With an improved experimental apparatus, W Ehrenberg and HuChienShan find that slow neutrons are absorbed exponentially by cadmium and silver, with production of radioactive elements This suggests that either the active neutrons are of fairly homogeneous speed or that a difference in speed does not greatly affect their chance of collision with the nuclei

Van't Hoff predicted sixty years ago that optically active substituted compounds could be prepared from the hydrocarbon allene By means of optically active catalysts, Dr Peter Maitland and Dr W H Mills have now succeeded in preparing stable dextro and lævorotatory allene derivatives

Dr A Muller has calculated from X-ray data the volume occupied by a CH_2 group in organic compounds of the straight chain and of the ring type The molecular volumes are identical at low temperatures, but as the temperature increases the CH_2 in a straight-chain compound occupies more space than that of a ring compound, possibly due to its greater mobility

Having observed a heart-urchin, *Echinocardium cordatum*, climbing on the vertical wall of a glass tank, a way in which it never acts in its natural surroundings, Prof E W MacBride suggests it is the result of a latent habit, inherited from ancestors more like the ordinary sea-urchin, which is pre-eminently a climber

Potassium salts increase the lactic acid formed in brain tissue, through the breakdown of glucose (in the presence of oxygen), and calcium opposes the effect produced by potassium K Dixon and Dr E Holmes believe this to be due to a change in the permeability of the cell membrane, which regulates the amount of glucose that reaches the cell enzymes, and that oxygen, like calcium, decreases this permeability.

J G. Bald finds that the relation between the concentration of virus particles introduced into host plants and the number of lesions produced, as expressed by the formula of Youden, Beale and Guthrie, applies only to carefully purified suspensions of virus

From measurements of the intensity of soft X radiations obtained from copper, nickel, cobalt and iron, and from the distribution of electronic energy deduced therefrom, F C Chalklin infers that the electrons in those elements are not completely free and cannot normally occupy the whole of the space in the lattice of the metallic crystal

In a previous communication dealing with the wings accompanying the primary scattered line in the Raman spectrum of liquids, Dr E Gross and M Vuks gave, as for naphthalene, certain data and a photograph obtained with a *p* dibrombenzene crystal They now correct this error, and give additional data concerning oscillation frequencies in the region of the wings, and the state of polarisation of new lines in crystals of *p*-dibrombenzene and diphenyl ether

Deviations from the gas laws may arise from the existence of a definite distribution of positrons and electrons in equilibrium with temperature and radiation From this effect S Chandrasekhar and Dr. L Rosenfeld deduce the possible existence of stars of very large mass and low luminosity, similar to the white dwarfs, owing their stability to different causes

By analysing magnetically the ions produced in mercury vapour at various pressures and voltages, Dr F L Arnot and J C Milligan show that molecular mercury ions exist. These are apparently formed only by the union of two atoms, of which one at least must be excited, a fact which may explain the conflicting evidence concerning the existence of mercury molecules.

When solutions of sodium oleate (soap) and other colloids are frozen, their particles, as shown by the speed of diffusion, aggregate if the concentration is higher than 1 5 per cent, and disaggregate if the concentration is less than 1 per cent, according to Dr F F. Nord and F E M Lange This may explain the temporary increase in activity of frozen solutions of certain enzymes, the increased fertility of soil after a severe winter, etc.

ERRATUM Dr. S. Mukerji writes to correct an error in the note on his letter in NATURE of April 6 He points out that the blood-sucking *Phlebotomus argentipes* is apparently the vector of *Leishmania donovani*, a protozoon which causes the malaria-like fever kala-azar in India *P. papatasii*, which is a vector of *L. tropica*, a protozoon morphologically identical with *L. donovani*, produces a localised skin infection popularly known as 'Oriental sore' or 'Delhi boil', and not the kala-azar fever.

Research Items

Celtic Mythology. In his Sir John Rhys Memorial Lecture for 1934, "Aspects of Celtic Mythology" (*Proc. Brit Acad*, 20 Separate, Oxford, Humphrey Milford, pp 44 3*s* net), Dr A G van Hamel puts forward the view that the mythical and heroic lore of the Celtic world in its succession of oath-strengthening gods, divine magicians, spirits of the land, and exemplary heroes, functioned as a guarantee of undisputed possession of the land Gods are rare in the original sources of Celtic lore, and there is little evidence, except as reported from Gaul, of worship or sacrifice The Immortals operated through magic, and the important element in relations with them is to avoid the infringement of taboo Throughout Irish myth and legend runs the idea of protection of the land, which is especially ensured by knowledge of the local traditions This gives power over the demoniacal forces associated with these localities There is a graduation in the magic of protection Highest come the 'divine magicians' who, while not actually gods, are immortals who protect the spirits of the land and the heroes such as Finn and his followers Next come the spirits of the land, the Tuatha de Danann in Ireland and the Children of Llyr in Wales, and thirdly there are the heroes—Finn in Irish story, Arthur with his knights, corresponding in Wales, and with them are the kings to whom the actual function of 'protection' is entrusted Although a great deal of folklore has gathered around both Finn and Arthur, it is improbable that either of them existed as men, although it is possible that in the latter a pre-existing function of 'protection' may have been attached to some prominent figure The common elements in the function of 'protection', which is directed especially against magical forces, as seen in their exploits of slaying wild animals, especially boars, points to the mythical origin in the two instances The significance of these heroes lies in their exemplary character They are paradeigmatic, that is, the recitation of the legends in analogous circumstances ensures the like event Hence the importance of the legends in education and the prominence of apprenticeship in the Druidical system

Early Indian Iconography. In connexion with the figure of a squatting goddess on the underside of a terracotta figure of a toad, Mr K de B Codrington has raised the question as to the derivation of certain hybrid forms, and of this figure in particular, in the early development of Indian iconography of the Mathura school (*Man*, May, 1935) The figure under consideration is in the Victoria and Albert Museum, South Kensington. It has no known pedigree, but almost certainly came from Mathura, the capital of the Kushan dynasty, and may be assigned to the early second century A D. This derivation is supported by the treatment of the figure and the details of the beaded belt, necklace and hair, which are all in the native Indian tradition. On the other hand, the position of the goddess and her association with the toad point to the Baubo toad-goddess myth, which Dr. M. A. Murray has brought into association with the Sheila-na-gig; and the possibility that the present specimen was intended for toilet use recalls the further point that Baubo was a hand-maiden Similar squatting goddesses, with hands touching the pudenda, are known in India, as, for example, the Bharhut goddesses and the railing figures from Mathura itself The derivation from the Baubo tradition is more probable than an indigenous origin Mathura was the scene of the development of Indian iconography, which at this time was just emerging The Kushans had just made their way into India from Central Asia, and on Kanishka's coins the Indian Buddha figure rubs shoulders with a polyglot and hybrid Olympus in which appear Helios, Mao, Athro, Manaio and others, while at the same time the hybrid so-called Greco-Buddhist art appears in Central Asia, Afghanistan and Gandhara If this figure be accepted as Baubo, it is one of the few, if not the only, example of a directly borrowed classical icon The type recrudesces at Badami in the sixth century, and in the Elura *Kailasa* which was cut by architects from the south In the female the posture is associated with the *Devi* in some of her manifestations as *Kali*

Correlation of Physical and Mental Culture. Dr L P Jacks in an essay in the *Hibbert Journal* (January 1935) deals with the new movement in physical culture, which aims at combining it with mental culture, and treating it as equally important This synthesis, he says, would give physical culture its rightful place in education, the true end of which is not the acquisition of knowledge but the harmonious development of the whole man At present this is realised only in the earliest stages of training—in kindergartens and Montessori schools though the increasing importance attached to manual arts and the steady development of the Scout and Guide movements are hopeful signs Exercises involving co-ordination and rhythmical 'patterned' movement are the chief features of the new physical culture, and it is obvious that what Carlyle called 'rhythmic human companionship' is essential for the welfare of the modern world. All our training must culminate in the interweaving of interests, if we are to bring order out of the present chaos, and humanity must change its habits as well as its opinions There is at present no true 'social' system, but everywhere the need and desire for it if a new type of education existed which developed in men's own lives the qualities they are always seeking outside, a solution might be found To achieve this, trained leaders are essential, and a new profession should be created, then, if the quality of the human material does not decline, the world may be saved

Beetles associated with Giant Lobelias and Senecios in East Africa. The giant species of *Lobelia* and arborescent *Senecio* constitute one of the most arresting features of the alpine floras of the isolated East African mountains Both these genera of plants are represented there by a number of species, which are characterised by highly discontinuous distribution It was, therefore, of exceptional interest to study the insects associated with these plants, and Dr Hugh Scott's work on the Coleoptera (*Linn Soc J*, *Zool*, 39; 1935) will be of value both to botanists and to zoogeographers Not less than 49 species of beetles belonging to 13 families were found in the association Only four of them are widely distributed, and can be regarded as casual visitors to the plants,

while all others represent a highly special fauna. The genera of which this fauna is composed are partly widely distributed, while the others are peculiar and are very restricted in their distribution. These are probably specialised components of the Ethiopian fauna. The genus *Thamnurgus* was, however, previously known only from the Palæarctic region. The association between the insects and the plants may be a very ancient one, and the possibility of a parallel development of both may be considered. It is remarkable that, while the alpine species of *Lobelia* and *Senecio* are giant members of the respective genera, some of the beetles associated with them are also gigantic in comparison with their nearest relatives. It is also of interest that about 50 per cent of them are flightless.

Development of a Nemertean. J. F. Smith (*Quart. J. Micro. Sci.*, 77, Pt. 3, 1935) describes the development of *Cephalothrix rufifrons*, a nemertean worm with a direct development. The spherical larva which issues from the egg is equipped with the rudiments of most of the adult organs. Owing to the confusion of the germ layers at the time of appearance of the mesoderm, the true nature of the secondary body cavity—whether it is a re-expansion of the blastocœl or a true cœlom—remains a matter of doubt. Gastrulation, effected by invagination, involves both endoderm and ectoderm, so that the blastopore is carried into the lumen of the gut; but this pore afterwards closes and the stomodæum and mesenteron are separated. Communication between these two parts of the gut is re-established later at or near the point of closure of the blastopore. A hind-gut is not formed until very late in development, and it is considered to be endodermal and not in the nature of a proctodæum, that is, not ectodermal. The formation of nephridia and of cerebral organs has not been observed and it is concluded that the latter are not present. The relationships of the various developmental types of the Nemertea are discussed and the conclusion is reached that there are two types of direct development, that the pilidium larva and the larva of Desor are more closely allied to the simpler direct, and least specialised type of development here described than to the other type of direct development seen in the Enopla.

Enteropneust Larvæ. G. Stiasny has published an account of the three Tornaria larvæ found in the Bay of Naples (*Pub. del Staz. Zool. di Napoli*, 15, Fasc. 1; 1935). Two of these, *T. Krohni*, Stiasny, and *T. tergestina*, Stiasny, are recorded for the first time in that neighbourhood. They are provisionally identified as the larvæ of *Glossobalanus minutus* and *G. elongatus* respectively. The third species is shown definitely to be the larva of *Balanoglossus clavigerus*. An account is given of the biology of *G. minutus*. Stiasny has also described elsewhere several exotic Tornaria larvæ (*Verhand. Kon. Akad. Wet.* (Tweede Sectie), 34, No. 2, 1934), of which two, *T. ramanujami*, a balanoglossid type of larva, and *T. uchidai*, a ptychodera type, are new species. Useful comparative tables are given of the diagnostic characters of the various species.

Growth and Tropistic Responses in Plants. Results of great interest are summarised by Prof. F. A. F. C. Went (*Biol. Rev.*, 10, No. 2) in an account of the modern work on growth and tropisms carried on in his laboratory. In these investigations the coleoptile of oats and other grasses, a hollow cylinder in which the first seedling leaf develops, has been of much use. If the coleoptile is amputated, growth stops for about three hours owing to the removal of a substance (auxin) evidently produced in the young tip. This substance diffuses into agar and can thus be used to measure the effect on growth rate when applied to other seedlings. Innumerable experiments with this basis have been carried out in the last decade. Auxin *a* can be obtained from animal urine, where it is in turn derived from plants. It is an organic hydroxy-acid, while auxin *b* is a keto acid, and a third growth substance discovered by Kögl is β-indolyl acetic acid. These substances have no effect on cell division, but they increase the plastic extensibility of the cell walls. Auxin retards the growth of roots, probably by extending the transverse cell walls. It moves only from tip to base of the coleoptile, its movement being very rapid and only accounted for by the aid of protoplasmic streaming. Its production is inhibited by ethylene, which stops growth when present in very minute quantities. Many experiments go to show that both phototropism and geotropism can be explained by the movement of auxin in the plant. The shaded side gets more auxin than the illuminated side, and so grows faster. Negatively geotropic organs respond in the same way, but auxin inhibits the growth of roots and so gives positive geotropic curvatures. The relation of these responses to the statolith theory is not discussed.

Germination Experiments with Peas in Heavy Water. J. Brun and L. Tronstad have made several series of germination experiments with two forms of peas (*Pisum sativum*) at high, intermediate and low concentrations of heavy water (*Kgl. Norske Videnskabers Selskabs Forh.*, 7, 171; 1934). Germination took place up to 40 per cent D_2O, but not from 50 per cent and upwards, which is in agreement with the results of G. N. Lewis with tobacco seeds. The alleged stimulation of growth at low concentrations could not be confirmed. The experiments were complicated by the formation of moulds, which took place up to the highest concentrations employed, namely, 98·4 per cent D_2O, as was found by K. F. Bonhoeffer and his collaborators.

Landslides in Japan. Prof. N. Miyabe has made a careful study of the distribution and phenomena of landslides in Japan (*Earthq. Res. Inst. Bull.*, 13, 85–113; 1935). They have recently been most frequent in the prefectures of Nagano and Niigata on the north west side of the Main Island, the rocks in which they occur being chiefly shales. The rates at which they move vary widely, from about a foot a year to 100 feet an hour. In the above prefectures, they occur most frequently in April, with a smaller maximum in July; the former may be caused by the melting of the previous winter's snow, the latter by the heavy summer rains. Thus, the factors most effective in starting landslides are (1) destructive earthquakes and (2) water, rain and melted snow.

Dust Separation by Electrostatic Methods. The most efficient method of removing dust and water, tar and other liquid particles from air and gas appears to be the electrostatic method of which Sir Oliver Lodge

was the pioneer more than fifty years ago. There are now some 3,000 electric filters employed in a wide range of industries, and 95–98 per cent of the total dust can be removed from the gaseous medium irrespective of the size of the particles. In an article on the advantages of electrostatic methods of dust separation published in the March number of the *Electrical Power Engineer*, it is stated that the modern 'Lodge-Cottrell' service represents an association of the patents, researches and experience of several companies. It includes the companies of Sir Oliver Lodge and his associates in Great Britain, Dr. F. G. Cottrell in the United States and Dr. Erwin Moller in Germany. The basic principle consists of towers through which passes the fume-laden air. In the towers is a series of vertical metal pipes called the collector electrodes which are connected with the earth. The discharge electrodes are from points on rods or wires hung close to the collector electrodes. These are connected with a high-tension power supply, and thus brush discharges take place from the points. All the solid and liquid particles in the fumes are repelled against the collector electrodes and either fall down to the bottom of the tower into a hopper, or adhere to the electrode, the dust-free air or gas passing on. To get rid of the adhering particles, motor-driven rapping hammers vibrate the electrodes and shake off the dust. The high voltage is produced by a motor-driven rectifier operated by the ordinary electric supply. Owing to recent improvements, the electric power required per million cubic feet of gas is less than two electric units (2 kwh.).

Failure of Aircraft Propellers in Flight. With the ultimate aim of solving the larger problem of the causes of failures of aircraft propellers in flight, a very interesting series of investigations into the effects of vibration is being made at the National Bureau of Standards of the U.S. Department of Commerce. The fatigue fractures usually exhibited suggest that such failures are due to alternating stresses set up by vibration and, in order to obtain data on this aspect of the problem, it was decided to ascertain experimentally the frequencies and stress distribution of non-rotating blades subjected to vibration, and to compare with these the values as computed by the usual theoretical methods (*J. Research Nat. Bur. Stand.*, Feb. 1935). The experimental procedure consisted in applying, at the hub, controlled impulses and in measuring the amplitudes of tip vibration and the corresponding strains at various points along and across the blade. From these observations, stress distributions for both fundamental and second harmonic modes were obtained. For the calculation of the same values theoretically it was necessary to simplify the problem by making such assumptions as that all cross-sections are symmetrical and their axes of constant direction. The very divergent results obtained would appear to throw doubt on the validity of such assumptions, particularly in their influence on frequency values. It would seem almost necessary in such a case where the actual blade of experiment differs so materially from the theoretical blade of calculation to make a blade conforming to the theoretical conditions, and to compare the experimental results obtained from it, on one hand, with those of the actual blade, and, on the other hand, with the theoretical results which, properly, apply to it. Such an intermediate experiment would considerably help in determining the value of the investigation.

Tautomerism of Acetyl-Acetone. That acetyl-acetone exhibits tautomerism has long been discussed in text-books, but that several tautomeric forms of the compound can co-exist is less familiar (G. T. Morgan, *J. Chem. Soc.*, April 1935). Examination of its reactions with the tetrachlorides of selenium and tellurium have revealed its complex nature. The univalent radical $C_5H_7O_2'$ is known to combine with many different elements to form three distinct types of derivatives, but selenium and tellurium differ from other elements in yielding derivatives of the bivalent radical $C_5H_6O_2''$. It is shown that whereas the *trans* monoenolic form reacts with other elements, selenium tetrachloride selects the *cis* form, whilst tellurium tetrachloride prefers the dienolic modification, ultimately yielding a *cyclo*telluropentanedione. Further studies have revealed the existence of a deep-red bisarylditelluride, which is an analogue of azobenzene.

Geometrical Transformations. One of the most important topics in analytic geometry is that of Cremona and other rational transformations. The older work in this subject has been summarised in the "Encyklopädie der mathematischen Wissenschaften" and Bulletin 63 of the National Research Council (Washington, 1928). Miss H. P. Hudson's "Cremona Transformations in Plane and Space" appeared in 1927. So much work has been done since these publications appeared that it has now been necessary for the National Research Council to issue a supplementary report ("Selected Topics in Algebraic Geometry", 2, Bulletin 96). After a list of twenty-one books (none earlier than 1924), there follow six chapters dealing respectively with curved and ruled surfaces, mapping, systems of lines in n-dimensional space, Cremona transformations, multiple correspondences, surfaces and varieties. Each chapter ends with a bibliography, the shortest of which mentions 79 papers, and the longest 239. The report is of great value to the working geometer.

Spectroscopic Parallaxes of Stars. An important catalogue of spectroscopic parallaxes has just been published by Prof. W. S. Adams and others of the Mount Wilson Observatory (*Astrophys. J.*, **81**, 187; 1935). The methods used are the same as those in previous work of this kind, namely, the comparison of the intensity of a line sensitive to absolute magnitude with a neighbouring line of fixed intensity, calibrating curves connecting the intensity difference with absolute magnitude being constructed from the known data of trigonometrically measured stars. As some of the lines used are really blends, separate curves have to be drawn for groups of stars within narrow ranges of spectral type. The only differences between the method of this latest list and that of earlier ones from Mount Wilson lie in the use of some additional pairs of lines, and in the application of minor corrections to the reduction curves on account of the large increase in the available number of trigonometrical parallaxes. The new list contains the spectroscopic absolute magnitudes and parallaxes of 4,179 stars, mostly of types F–M, but with a few A-type stars, and includes most of the stars given in previous lists (completely re-measured). All Boss stars of these types north of declination $-26°$ are included as well as many fainter stars from the selected areas or of special interest on account of proper motion. This is the largest catalogue of stellar parallaxes hitherto published, and the Mount Wilson observers are to be congratulated on this result of their labours.

The Twin Polygraph and Strobograph

ULTRA-RAPID CINEMA-PHOTOMICROGRAPHY

By A. G. LOWNDES, Marlborough College, Wilts

THE process consists primarily of filming rapidly moving micro organisms by means of intermittent light. The source of light is an open arc light and the intermittent character is obtained by rotating, at high speed, a suitable disc, pierced by one or several slots, between the arc and the microscope. The number of exposures per second obtained in this way is almost unlimited while the time of each exposure can be made very small. Thus if the disc is rotating at 100 rev. a second, and there are 12 slots in it, the number of exposures will be 1,200 a second. If each slot subtends an angle of 1°, the exposure will be 1/100 × 1/360 = 1/36,000 sec.

FIG. 1. Twin polygraph and strobograph

Attached to the eyepiece of the microscope is a suitable cinema camera, and matters are so arranged that it is possible to see the object all the time it is being filmed. Nearly all cinema cameras work on the principle of the intermittent frame, or so that during exposure the film is still and then moves forward one frame; the shutter of the camera cutting off light during the change of frame. In filming micro-organisms this introduces a difficulty, for if an organism gives a spasmodic leap, the critical point is as likely to occur during cut-off as during exposure. In order to overcome this, a microscope is used possessing a single objective but two eyepieces, while the camera is constructed so that a film works in conjunction with each eyepiece, cut-off in one occurring during exposure in the other. Thus so long as the camera is working, continuous exposure is assured.

The next important point is that the speed of the camera is not that of the high-speed disc; the two are worked quite independently by separate motors. The speed of the camera is much lower than that of the disc, so that each frame of film will receive several images (hence polygraph). If the object is still, the images will be superimposed and will coincide, while if the object moves they will be spread over the frame of film.

With certain objects (for example, a cilium or the long antennule of a copepod) it is advantageous to get several images on one frame, and the interpretation and measurement of the movement presents little difficulty, but in other cases it is unwise to get more than three images on one frame.

The process was originally invented for the investigation of limb movement of minute Crustacea, or ciliary movement, etc., and was not intended for projecting purposes, but in certain cases these *polygraph* films were highly successful when projected. Two such films showing the movement of the ostracod sperms under the highest powers of the microscope were shown in Section D (Zoology) at the Aberdeen meeting of the British Association. For projecting purposes better films are obtained by the *strobographic* process, but such films are only obtainable if the object shows metachronal or rhythmic movements. In this case the high-speed disc carries one slot only and the speed is tuned-in to the object, giving the ordinary stroboscopic effect. The camera is then tuned-in to the disc so that a single frame receives a single image.

The advantages of the method are (1) the great saving in cost of film; (2) the comparatively low cost of the apparatus (camera, microscope, motors, arc-light and resistances, etc., £350); (3) the large number of exposures per second; (4) the ultra rapid exposures.

The alternative method of obtaining rapid exposures is by running the film through a camera at a very high rate. This is the principle of the slow-motion camera, and has the disadvantage that when in use film is costing about 3*s*. 9*d*. a second, while the camera itself (without microscope or lighting) may cost anything up to £2,000 or even more. The number of exposures is about 250 a second while the time of exposure is about 1/3,000 sec. Slow-motion films are, however, eminently suitable for projecting purposes. Another disadvantage is that the camera only attains full speed after an interval of 1–2 sec., and about 24 ft. of film is wasted every time the camera is stopped.

In the polygraphic and strobographic processes speed and exposure depend on the disc only, and this can run continuously without using film. So far, a speed of 24 frames a second has proved ample, and with a twin film the cost is 6*d*. a second, or 3*d*. with a single film. The speed of the disc can be varied and the slots are adjustable, so that the time of exposure, the interval between exposures, and the number of exposures a second can all be adjusted to suit the

object. The camera can be driven at speeds varying from 20 to 120 frames a second, while a single or twin film can be used. At these low rates the camera can be started or stopped practically instantaneously without loss of film, and one can expose either 1 ft or 100 ft.

The apparatus is somewhat cumbersome, since the arc and high-speed disc must be on separate stands or tables from the camera and microscope, while in high power work the camera itself with its motor must be insulated from the microscope, otherwise vibration will cause difficulties.

International Congress for Scientific Management

THE International Congress for Scientific Management to be held in London on July 15 and subsequent dates is the sixth of a series which have been held in various European capitals since 1924. The hosts of the Conference are a Council—nominated by a number of societies interested in one phase or other of the management movement, and the technical societies—which has appointed an executive committee composed of outstanding industrial leaders and others with Sir George Beharrell as chairman. The patron is H.R.H. The Prince of Wales. The organisation is in the hands of committees having as chairmen, Dr. E. F. Armstrong, Sir Henry Fowler, Mr. G. R. Freeman, Sir George Courthope, Prof. Winifred Cullis. The genesis of the invitation is the desire both to entertain the delegates in England, to show that Britain has a factory and business organisation fully up to the most modern practice, and to arouse public interest in general in the subject of scientific management.

The work of the Congress is divided into six sections each of which will hold four technical sessions. The sections will deal with development, distribution, educational and training, manufacturing, agricultural and domestic management respectively. At each session, papers falling under a specific heading will be discussed. The papers, of which there are two hundred, in six distinct volumes, are already in type and have been circulated to members; each paper has a summary in three languages. The papers for each session have been summarised by an expert *rapporteur*, which summary alone will be read, leaving the session available for discussions which are to be the main feature of the meeting. Presidents of eminence—in all twenty-four—have been obtained for each session.

The Conference will be opened at noon on July 15 by H.R.H. The Prince of Wales, who is taking a keen interest in it and is expected to speak at some length on particular phases of the subject.

The subject chosen for the first plenary session is the topical one of management problems arising from Government intervention, which is expected to give rise to an illuminating discussion.

The second plenary session will be devoted to consideration of the simplification of data, the place of statistics and the standardisation of terms.

A large number of visits has been arranged to factories and to places of interest for members of the agricultural and domestic science sections.

At the end of the Congress, tours have been arranged in special trains with sleeping cars to enable the overseas visitors to combine the inspection of some of our most famed scenery with visits to some highly organised factories, chosen so as each to illustrate a different phase of the management problem. The social side of the Congress has not been neglected and every opportunity will be given for members to fraternise.

Many of the papers are of outstanding interest and make important contributions to the development of management regarded as an exact science; the authors of the British papers were invited to contribute them by the organising committee as representing the best experience in the particular phases. The information accumulated in the volumes is such that no industrial library can afford to be without them.

It is anticipated that the Congress will have a large, if not a record, membership, but its arrangements have been made as far as possible sufficiently elastic to allow for expansion. There are few in business or wishing to attain managerial rank who are unlikely to profit by attending its deliberations; moreover, every support is deserved by the organisers, who are working on a purely voluntary basis with the sole object of giving testimony to the up-to-date state of British business organisation in every phase of activity.

Intending members should apply immediately to Mr. Harry Ward at 21 Tothill Street, Westminster, S.W.1, so that they may receive the Congress papers in ample time to give them the necessary study.

Fuel Research in Great Britain

THE Fuel Research Station at East Greenwich was open for inspection on June 4, and about 250 guests were received by Sir Harold Hartley, chairman of the Fuel Research Board, and Dr. F. S. Sinnatt, Director of Fuel Research. The whole of the plant was on view, and the work in progress was explained and demonstrated.

Particular interest was taken in the new semi-commercial scale plant for the hydrogenation cracking of tar to motor spirit. This plant commenced working on March 1, and was on view for the first time. It is designed to deal with 300 gallons of tar or creosote a day. One passage through the plant converts about half the tar to motor spirit, and by recirculating the residue the whole of the tar can be converted, yielding an equal volume of spirit. Demonstrations were given of a new plant for the dry cleaning of coal, while a washery table was preparing 'ultra clean' coal containing less than 1½ per cent of ash, from a commercial coal containing about 5 per cent. The coal survey that is being carried on throughout the coal fields of Great Britain has shown that large quantities of 'ultra clean' coal of various types can readily be prepared if required for special purposes.

The pulverised fuel burners designed at the Fuel Research Station, and now in commercial use, were

shown working in both Lancashire and water tube boilers. A method of dividing a stream of air borne coal into two equal streams was illustrated; owing to the unequal distribution of the coal over the cross-section of the pipe when pulverised coal is carried in a stream of air, this equal division has presented difficulties. An ingenious device for estimating the rate of settlement of a suspension of a solid in a viscous liquid was on view. The tube containing the suspension forms part of a pendulum, the change of the period of swing of which is a measure of the rate at which the centre of gravity of the system moves downwards. This apparatus was designed for investigations into the stability of suspensions of coal in oil, but may have other applications.

The experiments in the full-scale horizontal gas retorts, showing the advantages of introducing steam during the last portion of the carbonising period, were of special interest to gas engineers.

Fauna of Indian Salt Lakes

LIEUT.-COL. R. B. SEYMOUR SEWELL has made an interesting study of the fauna of the salt lakes of Calcutta (*Rec. Ind. Mus.*, 36, Part 1, 1934). Recent changes in the general character of some of the rivers in Lower Bengal have had a profound effect on these salt lakes and their associated streams, indirectly influencing the general character of the fauna of certain areas, silting in the rivers and canals due to various causes being the main factor in these changes.

The chief zoological interest in this brackish water area lies in the fact that it forms one of the main highways by which marine organisms gradually establish themselves in fresh-water. In the neighbourhood of the large river estuaries there is a very great amount of available food, both organic and inorganic, and there is a considerable lowering of the salinity in the surface water. The coastal species must be able to withstand a wide variation of salinity, and a further step from brackish- to fresh-water would not be difficult.

The region was almost certainly part of the Bay of Bengal, and with a gradual extension of the delta seawards the water of the rivers and lakes became less salt, but extremely slowly. Both marine forms from the coastal waters and fresh-water species from the rivers would be carried into the salt lakes. There seem to be few instances of a definite attempt at migration upstream from the sea to the fresh-water areas above the influence of the tide.

Although other groups are mentioned and to a certain extent listed, the copepods are studied in the greatest detail. There are true fresh-water forms in the Hooghly River, and in the salt lake with the pools and canals there are normal brackish-water forms; associated with the latter we may get definitely marine forms, a gradual change from fresh-water to salt-water species showing in the plankton from the fresh-water of the river system towards the sea.

With regard to the widely distributed *Pseudodiaptomus*, it is a question whether migration has been from the sea into fresh-water or from fresh-water to the sea, or from brackish-water into both regions. The author is of the opinion that it is of marine origin, and that there has been, and still is, a tendency towards migration into brackish- and on into fresh-water.

University and Educational Intelligence

CAMBRIDGE.—Mr. G. H. A. Wilson, Master of Clare College and formerly M.P. for the University, has been elected Vice-Chancellor for the academical year 1935–36.

Dr. W. H. Thorpe, of Jesus College, has been re-appointed University lecturer in entomology. Dr. D. H. Barron has been appointed University demonstrator in anatomy.

Miss Dorothy Hill, of Newnham College, has been awarded a Senior Studentship by the Royal Commissioners for the Exhibition of 1851.

OXFORD.—Dr. N. V. Sidgwick has been granted the title of professor during the tenure of his readership in chemistry.

Dr. A. H. Gardiner, vice-president of the Egypt Exploration Society and research professor of Egyptology in the University of Chicago, has been elected honorary fellow of the Queen's College.

IN order to encourage research on eugenic problems, and on the genetical and statistical methods needed, if they are to be profitably attacked, the Eugenics Society has decided to provide the funds for a research studentship of £250 a year, tenable at any of a number of suitable research departments in the United Kingdom. The studentships will bear the name of Leonard Darwin, honorary president of the Society. To make the awards and administer the studentships, an independent committee has been set up with the co-operation of the Royal Society, the Royal Society of Edinburgh, and the Royal Statistical Society. The studentships will be renewable for a second year.

THE Social Studies final report of the American Historical Association (Scribner, 1934, pp. 168, 1.25 dollars) has become one of the chief subjects of educational discussion in America. Dealing as it does with some of the most vital issues of contemporary social life in that country and being, according to one critic, a "daringly realistic" indictment of the present social order, it has, naturally, come in for a good deal of abuse. In *School and Society* of March 30 appears an address by Prof. Jesse H. Newlon to the American Educational Research Association, in which some of the attacks on it are answered. Among these are complaints of paying lip-service to democratic ideals while knifing them in the back by enlarging on trends towards collectivism, of countenancing the indoctrination of students with subversive ideas, of decrying objective tests and the scientific method generally, of needlessly disparaging existing methods of instruction in teacher-training institutions as mechanical and sterile, of irrelevant criticism of systems of control and administration of schools. The answers throw much interesting light on current educational practices. Prof. Newlon holds that the scientific method has become a sort of fetish—educational research being concentrated on it as a chief objective in the delusive belief that it can not merely illuminate, but also provide qualitative solutions of problems of educational policy. Summing up the significance of the report, it dares, he says, to make a social analysis and, in harmony therewith, to recommend policies for making education a more effective instrument for social reconstruction.

Science News a Century Ago

Cholera Statistics for 1831-32

On June 15, 1835, Sir David Barry read a paper to the Statistical Society "On the Statistics of Epidemic Cholera as it occurred in Great Britain between the 26th of October 1831 and 31st of December 1832" Sir David divided his paper into two main parts dealing respectively with the progress of cholera in Great Britain and in the Metropolis The disease, he said, prevailed as an epidemic in London during the ten months February 9 until December 31, the whole number of new cases being 11,020 and of deaths 5,275 The total numbers of new cases and deaths, for Great Britain and the Metropolis, were 80,203 and 30,924 respectively In concluding his paper, he made observations on the quarantine regulations, in the course of which he said that the history of cholera by no means justified the apprehension which re-enacted the old expensive plague-precaution system of delaying the landing or sale of cargoes, until the promulgation of a paper by the Central Board of Health in January 1832 entitled "Reasons founded on Authentic Facts in the History of Spasmodic Cholera, for establishing a Specific Code of Sanitary Restrictions for that Disease, considered independently of Plague, Yellow Fever, and other Infectious Maladies" put a period to the evil England having thus taken the initiative in the amendment of the quarantine laws, considerable mitigation very soon followed in other countries, with great relief to trade and without compromising the security of the public health

Sir David Barry (1780–1835) had been employed by the Government to investigate the yellow fever epidemic at Gibraltar in 1828; and, on the outbreak of the cholera epidemic, was sent to Russia to report on it.

Metamorphoses in the Crustacea

Among several papers submitted to the Royal Society on June 18, 1835, was one "On the Supposed Existence of Metamorphoses in the Crustacea" by J. O Westwood, secretary to the Entomological Society A report of this paper in the *Philosophical Magazine* said · "The author refers the principal modifications of form which occur during the progressive development of animals to the three following heads · 1st, that of an animal produced from the egg in the form which it is destined to retain through life, its only change consisting of a series of moultings of the outer envelope, attended merely by an increase in size, and not by the acquisition of new organs; 2ndly, when the animal at its exclusion from the egg, exhibits the form which it continues to possess, subject to a series of moultings, during several of the last of which certain new organs are gradually developed; and 3rdly, when the form of the animal at its exclusion from the egg, is totally different from that under which it appears at the later periods of its existence, such change of form taking place during two or three of its general moultings, and consisting, not only in the variation of the body, but also a complete change in the nutritive and digestive systems and in the acquisition of various new organs. This last phenomenon peculiarly characterizes what is termed a metamorphosis . . ."

Balloon Excursion Extraordinary

Under the above title, the *Mechanics' Magazine* of June 20, 1835, quoted the following extract from the *New York Journal of Commerce* relating to a balloon flight a short time before "Mr Clayton, a volunteer aeronaut in the West, made an ascent from Cincinatti, and was observed to pass off in a south-easterly direction Nothing more was seen of him for a number of days and great anxiety was felt for his safety. At length, nine days after his departure, he returned to Cincinatti, having made the most extraordinary excursion on record He did not, indeed, ascend as high as a number have done before him, but the distance he sailed is beyond all precedent, being not less than 350 miles All this was accomplished in 9½ hours, which is at the rate of nearly 37 miles an hour The greatest height to which he ascended was about 2½ miles " Commenting on this, the *Mechanics' Magazine* said "The longest aerial voyage previously on record was, we believe, that of M Garnerin in 1807, who travelled 300 miles in 7½ hours"

Control and Use of Poisons

THERE has recently been published the first report of the Poisons Board to the Home Secretary* The document contains the report proper, together with the Poisons List which the Board is required by the Pharmacy and Poisons Act to prepare, and a draft of Poisons Rules which the Board recommends shall be made by the Home Secretary. The provisional proposals of the Board were published in the autumn of 1934, and, doubtless as the result of representations since received, have been substantially modified in certain particulars in the present report The greater part of the Board's recommendations has to do with the control of the supply of poisons to the public, but owing to the present-day widespread use of some poisons in scientific and industrial work, the contents of the report are of interest to many others than those engaged in the preparation of medicines or the sale of poisons

The Board explains that, in preparing the Poisons List, it has so far as possible specified by name each individual substance included, and has endeavoured to avoid phrases such as "all poisonous alkaloids" which have the appearance of begging the question "What is a poison?" It has endeavoured also to avoid the use of group names, but the ingenuity of the organic chemist has compelled the adoption of an omnibus description such as 'derivatives' for some groups It is driven to the adoption of precise technical terms in the Poisons List, and the mystification of the layman at these "words of learned length and thundering sound" is to be provided for by the publication of a detailed, non-statutory, explanatory list.

In determining the inclusion of substances in the List, the Board has had regard to the following considerations:

"The danger of death or injury following

(1) the administration of a poison for criminal purposes,

(2) the swallowing of a poison in mistake for an innocuous substance,

(3) the inhalation through ignorance or by accident of the vapours given off by a poison,

(4) the incorrect compounding of medicines containing poison,

(5) the accidental taking in too large a dose of a medicine containing a poison."

* Home Office Report of the Poisons Board in regard to the Poisons List and Draft Poisons Rules prepared in accordance with the Pharmacy and Poisons Act, 1933 (Cmd 4912) Pp iv+62. (London: H.M. Stationery Office, 1935) 1s net.

Suicide is largely ruled out as a risk which can be guarded against, presumably on the ground that, though you may prevent a would-be suicide from obtaining a poison, many other means remain available by which he can accomplish his intention. Aspirin is discussed and rejected for inclusion in the List, the fatalities due to its use being insignificant when compared with the vast number of persons by whom it is used. The possible legal difficulty caused by the presence of arsenic as an impurity in many forms of matter, and of cyanides and other poisons present in plants, is left by the Board to the good sense of those concerned, the gardener purchasing *Lobelia*, for example, being thereby freed from the necessity of buying his seedlings from a pharmacist and signing the Poisons Register into the bargain. Special provision is made for the purchase of poisons by persons in charge of laboratories and generally by those requiring them for use in their trade, business or profession, so that there will be no interference with the normal business of the laboratory supplier.

An interesting proposal about which there will be controversy is that for the supervision of the manufacture of pharmaceutical preparations containing poisons. The proposal is that such operations shall be supervised by a pharmacist, a medical practitioner, a member of the Institute of Chemistry, or by a person who for three years has been engaged in such work. The basis upon which these proposals are made is that members of each of the first three classes are subject to disciplinary control, a corrective to which the holders of university degrees are not amenable. Nevertheless, a proposal which will in the future compel a graduate to subscribe to the Institute of Chemistry if he is to practise in a certain branch of industry is one which will scarcely commend itself to the universities or to the chemical profession as a whole, and it would appear that further consideration of this proposal will be necessary before the rules are actually made by the Home Secretary.

Among substances included for the first time in the List are a number of antipyretics, of which acetanilide and amidopyrine are examples. Acetanilide has largely gone out of fashion, even if it does not wholly merit the *ex cathedra* dictum of the late W. E. Dixon that "it is a drug which ought never to be given under any circumstances". The addition of amidopyrine is presumably the outcome of recently published papers upon the effects of this substance in producing agranulocytosis in susceptible people, and time alone will show whether the Board has been stampeded by the chance publication of papers contemporaneously with its own work or whether it has in fact wisely anticipated a public danger. There are in the List a number of substances which in their pure state may be regarded as museum specimens: ouabain, brucine, curarine and thebaine are examples.

Some recognition of modern developments in therapeutics and their potential dangers is seen in the inclusion of the active principles of the thyroid, pituitary and suprarenal glands. Certain substances are to be restricted in their distribution to a medical prescription, among them the nitrophenols and nitrocresols, which had a short-lived vogue for slimming and, owing to their uncertain action in stimulating oxygen consumption, have led to fatalities. In this class too are the derivatives of phenylcinchoninic acid, which have given rise to toxic jaundice of the liver, and the derivatives of barbituric acid, around which the "battle of the barbiturates" raged a year ago. Thallium salts might reasonably have been added, although their uncertain action has presumably led to their general abandonment in medicine in recent years.

A general survey of the report, the Poisons List and the Rules shows that the Board has performed its detailed and thankless task with great thoroughness and, it is to be hoped, with a fair measure of success. It is satisfactory to note that the personnel of the Board is largely technical, comprising physicians, pharmacists, chemists, toxicologists and agriculturists. How far representation could have been extended to include other interests and other experts is a debatable question. There obviously comes a limit beyond which selection cannot go. Nevertheless, the omission from the Board of one or more representatives of the large-scale industrial manufacturers of poisons is noteworthy, although there may well have been difficulties in the way of such an appointment, since selection among competing firms is not easy. Up to a point, the absence of such representation is compensated for by the provision in the Act requiring consultation with industrial interests before the rules are made.

It is to be hoped that this thorough revision of the poisons legislation of Great Britain will justify the pains that have been spent upon it. The revision of the List is a piece of work which badly needed doing, and it has been done thoroughly. But the

rules bear the mark of the heavy hand of the lawyer The present "patchwork of provisions" has worked by the administering authorities accommodating themselves to the facts of the trade in poisons, while the Rules substitute for the discretion of the authorities a large number of detailed provisions In future, everybody concerned should at least be able to find his position set out in black and white, but there may well be some who, after a close reading of the rules, will echo the doubts of Mr Weller's charity boy on arriving at long last at the end of his alphabet

Reviews

Physics and Mechanics of the Metallic State

(1) *Handbuch der Metallphysik* Herausgegeben von Prof Dr G Masing Band 1 *Der metallische Zustand der Materie* Teil 1 *Gitteraufbau metallischer Systeme*, von Prof Dr U Dehlinger, *Grundlagen des metallischen Zustandes, Physikalische Eigenschaften der Metalle*, von Prof Dr G Borelius Pp xiii + 520 (Leipzig Akademische Verlagsgesellschaft m b H, 1935) 47 60 gold marks

(2) *Distortion of Metal Crystals* By C F Elam (Mrs G H Tipper) (Oxford Engineering Science Series) Pp xiii + 182 + 5 plates (Oxford Clarendon Press, London Oxford University Press, 1935) 15s net

THE investigation of metals by physical methods has undergone a remarkable development during the last fifteen years To this progress both physicists and metallurgists have contributed On one hand, metals and alloys can now be examined over a much larger range of temperature and pressure, and in much stronger magnetic fields than was previously the case The application of methods of X-ray analysis enables the lattice structure to be ascertained in which the positions of the atoms and the distances between them can be experimentally determined It is now possible, in the case of any solid alloy, to determine not only the number of phases at any given composition, but also the distribution of the atoms in those phases For this reason, the microscope and the X-ray spectrometer have become twin instruments for the characterisation of the structure of any metal or alloy During the period in question, theoretical physicists have been paying increased attention to the problems of the metallic state On the other hand, the new technique devised by metallurgists for the production of single crystals of metals by a variety of methods, has placed in the hands of physicists the most perfect form of any metal for investigation In addition, the progress of metallurgical research has rendered available a far larger number of metals in sufficient quantities for investigation than was previously the case Add to this the fact that the majority of metals are now available in a state of purity which exceeds 999 parts per thousand, and it will be seen that all the conditions are present for an intensive investigation of them by the best methods of physical research

Metals are now forthcoming in two different states—the polycrystalline and the monocrystalline The former represents what may be called their ordinary state in that it results by the usual methods of preparation The latter can only be obtained by some form of controlled crystallisation Some properties, such as specific heat, can be equally well determined in either state There is no difference in the value obtained Other properties, such as electrical resistance, which is the same in all directions in cubic crystals, but not the same in the case of non-cubic crystals, can in the former case be determined equally well on polycrystal specimens, apart from any special influence of crystal size In the case of non-cubic metals, however, such properties can only be completely investigated with single crystals, where the directional effects can be determined A polycrystal specimen in such a case would give a mean value if the directions of the axes are completely at haphazard In forged and drawn specimens, however, particular directions often predominate Finally, properties such as the intensity of magnetisation of a ferro-magnetic metal, which even in the case of cubic crystals depend on the direction, can only be determined on single crystals

The two books under review are examples of this modern work

(1) That edited by Masing is the first volume of a handbook of metal physics It is divided into two parts The first, contributed by Prof Dehlinger of Stuttgart, is devoted entirely to a study of the lattice structure of metals It is significant that almost all of them possess a high degree of crystal symmetry, and crystallise either in one form of the cubic or the hexagonal systems The only exceptions are gallium, indium, β-tin and γ-manganese which are tetragonal, and arsenic, antimony and bismuth which are trigonal The second part is the work of Prof Borelius of Stockholm, who sets forth a detailed survey and

examination of some of the principal physical properties of metals. Limits of space do not permit any detailed reference to either of these sections It can only be added that both of them are of great value, and will prove indispensable to students of these subjects

(2) The second volume under notice is the work of Dr. C F Elam In the author's words, the scope of the book has been limited to "an account of the changes in structure accompanying plastic deformation, changes in physical and mechanical properties, and factors such as temperature influencing these changes". A short account of the effect of heat on deformed metal is also included The author's aim has been to avoid unnecessary experimental details and to lay stress on methods, particularly those employed in investigations of the distortion of single crystals This monograph is written with great ability and remarkable fairness, and clear distinctions have been drawn between the facts established by experiment, the inferences to be drawn from them, and the theory of the phenomena involved It will be found very helpful by investigators in this field of research

Both books are admirably printed and illustrated, but has not the time come when a protest should be made against the excessive 'loading' of the paper, which adds greatly to their weight? This is particularly the case with the German treatise. It is possible, though it is more difficult, to get satisfactory results with a lighter paper, and it would make the book in question much more convenient to use H C H C

Diet and Health

Gesundheit durch richtige und einfache Ernahrung. Von Mikkel Hindhede Gekurzte deutsche Ausgabe von Lothar Meyer. Pp. x+196 (Leipzig. Johann Ambrosius Barth, 1935) 5 40 gold marks

OUR adopted standards of diet consisting of 100 gm protein, 100 gm fat and 500 gm. carbohydrate with an energy value averaging 3,000 calories are derived from statistics of the food consumption of families in various cities. There is no difference of opinion about the caloric value, but the amount of protein has been much discussed and agreement has not been reached. In Great Britain the special committees of the Medical Research Council and the British Medical Association have adopted 50 gm. of animal or first-class protein as the minimum to be aimed at in compiling diets.

Many years ago, Dr Mikkel Hindhede questioned whether so much protein was necessary, and whether it were better derived from animal or vegetable sources. He himself lived and brought up a family of children on a diet containing about 67 gm total protein, mainly vegetable. The children were of equal stature to others and capable of great physical endurance. The cost of the diet (pre-War) was about 4*d* a day. Country people in Europe likewise exist upon, and bring up healthy families with fine physique, on diets with even less protein Hindhede thus came to doubt the accepted high protein standard With the help of the vegetarian, F. Madsen, he started numerous experiments of long duration to ascertain the minimal amount of protein for maintenance Madsen and also other subjects lived upon various low protein diets with perfect health. The most striking one was potato and fat in which the daily amount of protein was only 32 gm This diet was also tried by the other subjects with success. It is pointed out that the healthiest and strongest men in Ireland live mainly on a potato and fat diet. Later, successful low protein experiments were made with diets consisting of coarse wholemeal bread, or whole barley, or whole oats with a little sugar and considerable amounts of vegetables and fruits, but substitution of white bread for the whole grain was a failure The reason for the good value of the whole grain was due to the bran, which on trial was found to be easily digestible and to contain protein of high value similar to that of animal protein.

Though the amount of protein can be reduced to so low as 32 gm. a day, Hindhede does not advocate this minimum, but recommends 60–70 gm, mainly derived from whole meal wheat and potatoes, together with vegetables and fruits and occasionally some meat or fish His simple and standard diet consists of 500 gm coarse whole meal bread, 25 gm butter, 100 gm. margarine, 500 gm. potato and 100 gm. whole barley meal. It yields 60 gm of protein and costs about 6*d* a day. Not one in a thousand, he says, would live upon this diet; everyone would wish to add to it, partly from superstition that it is inadequate and partly from its lack of palatability. Should it be supplemented by animal or vegetable foods, that is, meat, fish, milk or eggs, or by vegetables and fruits? He considers the second alternative is right, but has no objection to animal foods, except that they should be eaten in small quantities The simple diet contains an abundance of all the vitamins and sufficient mineral salts. The addition of other foods will upset the balance. A list of foods is given Only fat meat and fatty fish and eggs are classed as really bad. White flour and sugar and sweets and confectionery are intermediate. Whole grain, vegetables and fruits are the best foods. There is agreement, except in

regards to fat meat, fish and eggs, with the results obtained from experiments on animals

The diet drawn up by Hindhede from his own work and experience is similar to those eaten by certain native races in the Himalayas and in certain parts of China and the East These peoples have the finest health and physique, and do not suffer from the intestinal diseases of the European or from cancer There seems no question but that Hindhede is right He refers to several institutions in which children have been healthily reared on diets of a similar nature In Levsin the best results with tuberculous patients are with those on simple and cheap diets There are people in Great Britain who live upon simple diets of this kind, but they are looked upon as cranks Most people, as well as the medical profession, are imbued with the doctrine of high animal protein and scarcely dare to make any alteration

This book should be translated into English and read without prejudice by the medical profession and the public The simple diet is the healthiest and the cheapest The cost of food could be reduced with advantage to health There would be improved manual work and the possibility of competition with the workers in Eastern countries The general lack of palatability of Hindhede's standard diet can be improved by proper cooking Numerous recipes are given, they are well worth a trial

Psychological Doctrine and Practice

(1) *An Introduction to Theory and Practice of Psychology* By Dr Ll Wynn Jones Pp x+308 (London Macmillan and Co, Ltd, 1934) 12s 6d net

(2) *Duke University Psychological Monographs* No 3 *Conation and our Conscious Life Prolegomena to a Doctrine of Urge Psychology* By Prof Helge Lundholm Pp 95 (Durham, N C Duke University Press, London Cambridge University Press, 1934) 4s 6d net

(1) IN this "Introduction", Dr Wynn Jones deals with the subject-matter of psychology from the purely psychological point of view, that is, independently of philosophical speculation and physiological interpretation, and bases his exposition throughout upon the groundwork of Spearman's well-known principles Though he by no means neglects the work of other schools of psychological thought, the author consistently and successfully applies these principles in all the chapters of the book, which deal in the main with problems of cognition

Dr. Wynn Jones's plan is to give the reader, and especially the university and training college student, a straightforward working knowledge of the science, its methods of investigation, and the application of statistical treatment to its data He accordingly introduces each topic by outlining an experiment which the student is expected to perform (Although some of these experiments require the resources and technique of the laboratory, for the most part they need little or no apparatus, and can easily be carried out on the lines of the directions given) The experimental data, thus presumably obtained by the student himself, but in any case already known, are next discussed at some length, and are illustrated by references to actual researches Though Dr Wynn Jones casts a wide net for his illustrations, it is of interest to note that many of these come from his laboratory at the University of Leeds and are borrowed from the theses of his own students It is in these "Discussions" also that the views of other schools are elaborated, and comparisons are drawn between the different theoretical interpretations of the data that have been advanced and those which the author himself advocates Questions upon the content of each chapter are then set for the student; and each chapter ends with a very useful bibliography The plan is a good one, and calculated to lead the student to the desired objective

As might be expected, Dr Wynn Jones lays great stress upon the securing of reliable introspective and objective data in experimental conditions, and the treatment of such data by appropriate statistical procedures. Time and labour have been lost in the past by accumulating masses of data which, for lack of a statistical instrument, were not, or could not be, scientifically handled In the same way much statistical calculation was worthless because of faulty or irrelevant data Neither complaint can be made in respect of this 'Introduction" Dr Wynn Jones also emphasises the importance of the study of individual differences both for the practice and for the theory of psychology

This volume is one of the now many evidences of the fecundity of the noegenetic principles and two-factor theory upon which it is based, and of the solidity of the foundations of exact introspection and mathematical analysis upon which they, in their turn, are grounded The principles themselves are briefly, though clearly, stated towards the beginning, and the statistical methods at the end of the book The intervening chapters cover a wide range of psychological topics, and should prove to be of great interest and value to the student

(2) This monograph is a closely reasoned argument in favour of a view widely held by contemporary psychologists, and to an increasing extent by general biologists, that the behaviour of

animal organisms cannot be interpreted satisfactorily on the basis of 'mechanical' concepts such as tropisms and reflexes, but at all levels of evolution requires a teleological explanation The reasoning is largely deductive from certain principles which Dr Lundholm postulates, but is also supported by empirical observations The assumption must be made that all animals experience inner urges towards goals the prosecution of which will satisfy their needs, and to this the further assumption must be added that conative experiences, the impulses themselves and their consequent activities, are directed by some kind of awareness, analogous to our own, which guides them to their goals

The thesis is also developed that specialised (instinctive) behaviour forms become differentiated from a more primitive, generalised form, in which curiosity, together with the impulses of deference or defiance towards the environment, give rise to adaptive behaviour In the first case the animal adjusts itself to its environment, in the second it modifies the environment so as to satisfy its biological needs The combination of these impulses working together leads to belief in the reality of the particular kinds of psychological objects that constitute the 'world' of the animal in question, from the protozoa up to man; and it implies both insight and foresight Curiosity, again, because of a law of the "affinity of cognitive dispositions", groups together similar psychological objects whenever a specialised impulse is activated, reinstating experiences of conative cycles set up by like impulses in the past Language provides names for such objects—'dangerous', 'valuable', and the like But when curiosity dominates its accompanying specialised impulse, there is no such selectivity, the mind reviews a general past in which event is related to event, and the objective relations between them are apprehended This makes the conscious planning of means towards ends possible

The monograph, which belongs to the literature of hormic psychology, shows traces of the influence of configurationism It is both suggestive and stimulating.

Naturalists on African Lakes

Inland Waters of Africa the Result of Two Expeditions to the Great Lakes of Kenya and Uganda, with Accounts of their Biology, Native Tribes and Development By S and E B Worthington Pp xix+259+40 plates. (London: Macmillan and Co, Ltd, 1933) 15s. net

DR AND MRS WORTHINGTON still found the place and occasion when the feel of a rifle was 'comfortable' during the night They were also 'roasted' in places fit for no human life, ran constant and inevitable risk in their small boats on great lakes, and had marmalade for breakfast in one of the special hells they saw fit to visit Such things make good reading, but cannot well be introduced into scientific papers, or official reports, and the authors have done a service in writing a general book, where the reader can find both enlightenment and entertainment

A further and better justification is that travellers, and especially such travellers, inevitably make many important and suggestive observations in geography, anthropology and natural history, which are not perhaps sufficiently complete or novel for scientific papers, but, when put together in this way, provide a very good picture of African life This will be of historical importance in only a few years' time, so rapid are the changes of the present age in Africa The fathers of some of the Worthingtons' most skilful clerks or artificers may have been cannibals What will the sons be?

Specialists and other students should look in this book for readable and, no doubt, very fair accounts of some interesting subjects A survey of primitive craft, culminating in the Baganda canoe, suggests evolution rather than dispersion. The decay of communal emotion, in favour of individual emotion, is traceable in a comparison of dances, of which a very fine account is given, including the music Canoe songs are not as well done as might have been expected, although it is good to have a record of the "Song of the Crowned Crane"

The changes in watersheds, with pluvial periods and earth movements, are well summarised in connexion with the distribution of species of fresh-water fishes, the last in itself a fascinating problem. Angling, food chains, farming the waters and artificial dispersion of species, are serious problems described The account of the solution of the *Tilapia* problem in Lake Victoria reads "Constant fishing every day throughout many years in the Kavirondo Gulf had reduced the stock of fish to such an extent that their breeding had been seriously affected", whereas the senior member of the Lake Victoria survey wrote, referring to the whole lake, " this diminution of stock has not yet gone so far as to reduce the number of ngege that annually enter the fishery" (1929, p 11)

The book is well printed, but would have been easier to read had the lines been further apart. Clear maps are in sufficient quantity and the photographs are interesting and beautiful, which means that serious difficulties of the tropics were surmounted. There is an index M G

Short Notices

An Index to the Genera and Species of the Diatomaceae and their Synonyms, 1816–1932 Compiled by Frederick Wm Mills Part 1 *A–Ac* Pp 74 Part 2 *Ac–Am* Pp 75–148 Part 3 *Am–At* Pp 149–222 Part 4 *At–Bi* Pp 223–296 Part 5 *Bi–Ch* Pp 297–372 Part 6 *Ch–Co* Pp 373–448 Part 7 *Co–Cy* Pp 449–526 Part 8 *Cy–Di* Pp 527–606 Part 9 *Di–Eu* Pp 607–684 Part 10 *Eu–Ga* Pp 685–762 Part 11 *Ga–He* Pp 763–840 Part 12 *He–Me* Pp 841–920 Part 13 *Me–Na* Pp. 921–1000 Part 14 *Na–Na* Pp 1001–1080 Part 15: *Na–Na* Pp 1081–1161 Part 16 *Na–Ni* Pp 1162–1240 Part 17 *Ni–Pl* Pp 1241–1320. Two groups of minute plants, the Desmids and the Diatoms, have long been subjects of study for those attracted by the elucidation of microscopic detail, and in both cases numerous species have been described and a complex synonymy has resulted An index to the species and synonyms of Desmids was published by Nordstedt in 1896 and has been of great value to workers on the taxonomy of these forms The fact that nothing altogether comparable has up to the present time been accomplished for Diatoms is no doubt to be ascribed to the wider range of literature to be traversed and to a more entangled synonymy The labour involved was in fact much greater and Mr Mills, whose index has been compiled over a long span of years, is to be congratulated on the successful achievement of so arduous a task

Since a work of this kind has a permanent value rather beyond the average, one cannot but regret that it is not printed, for even at this early date an appreciable proportion of the pages of the typescript bear so feeble an imprint that it may well be doubted whether they will be readily decipherable fifty years hence It is to be hoped that before then means will be found to secure a more permanent reproduction, for which the Royal Microscopical Society, to the fellows of which the work is dedicated, may perhaps be able to raise the requisite funds. The first part contains numerous typographical errors, a defect which is to be regretted since this part includes the principal bibliography. The final part contains a supplement with additional literature and a series of species omitted in the main body of the work.

F. E. F

Ancient Ireland a Study in the Lessons of Archaeology and History. By Prof R A. S. Macalister. Pp xii + 307 + 24 plates (London: Methuen and Co, Ltd, 1935.) 10*s*. 6*d*. net

In introducing "Ancient Ireland" to his readers, Prof. Macalister explains that it is in effect a supplement to his "Antiquities of Ireland", which appeared in 1927 He now approaches the material with which he dealt in the earlier work from a more anthropological point of view He has here essayed a reconstruction of the cultural history of Ireland from prehistoric down to historic times, including in his survey the renaissance of Celtic art in Christian times and the early churches and castles For the detailed evidence, upon which this reconstruction is based, the reader is referred to the earlier volume On certain topics, however, such as the origin and purpose of the prehistoric forts of Aran, the origin and meaning of New Grange, oghams and other matters, fresh evidence or a change of view have necessitated a restatement and recapitulation

One of the most important of such matters to which the author has given reconsideration is the break in bronze age culture, which the evidence of pollen analysis, not available to him at the time of writing, has now shown to come at the close of a climatic optimum In attributing the cultural eminence of the early bronze age not merely to wealth in gold, but also to the effects of a more favourable climate, the author has stressed an influence which he sees at work throughout Ireland's cultural history, and holds responsible for the cultural break between north and south—a break marked from the earliest times as in the distribution of the horned cairn, down to the present political division between Northern Ireland and the Free State, in which a bracing north east is opposed to the enervating south and west

On many questions—not least, perhaps, on the Celtic problem itself—Prof Macalister finds himself at a loss, in view of the gaps in systematic study of Irish antiquities The present activities of the State may possibly hold out promise of better things In the meantime, Prof Macalister, with his many and often brilliant suggestions, offers a plenitude of material for further discussion He never fails to be provocative, even when most convincing

Hormone und innere Sekretion Von Prof Dr Fritz Laquer (Wissenschaftliche Forschungsberichte, Naturwissenschaftliche Reihe, herausgegeben von Dr Raphael Ed Liesegang, Band 19) Zweite verbesserte und bedeutend erweiterte Auflage Pp xii + 368 (Dresden und Leipzig Theodor Steinkopff, 1934) 18 gold marks

The second edition of this very thorough work of reference follows seven years after the first Dr. Laquer (who should not be confused with Dr Laqueur, the distinguished Dutch physiologist working in the same field) has himself been very active in hormone and vitamin research, and it is all the more creditable that this should not have involved the restriction of his bibliographic activities

The present book is an extremely useful consequence of those activities, covering, with abundant references and literature indexes, the whole field of endocrinology in its chemical and physiological

aspects. To have done this in 368 pages, which include 6 pages of index and 126 pages of literature references, involves immense condensation, and leaves little room for any expression of the author's own opinions Perhaps, in a field where to-day so much is speculation and controversy, this is not altogether to be regretted. An indication of the relative apportionment of subject matter can be obtained by considering the bibliographical references To the general section there are 123, to the sections on the enzymes of the pancreas, thyroid, parathyroid, adrenal, pituitary, reproductive, and miscellaneous glands (including the thymus, spleen, intestinal tract, pineal body, etc.) there are respectively 1,245, 1,000, 337, 1,092, 1,237, 910, 688

For these references alone the book is one to be welcomed, it is only the specialised experts working in each individual field who can precisely assess the value of the book in its particular aspects

A L B

The Application of Absorption Spectra to the Study of Vitamins and Hormones By Dr R A Morton Pp 70+6 plates (London Adam Hilger, Ltd, n d) 10*s*. net.

THIS small volume, which deals mainly with vitamins and scarcely at all with hormones, gives a concise and excellent summary of the achievements of absorption spectroscopy as a valuable adjunct in the isolation and identification of naturally occurring compounds which are present in extremely low concentrations. Dr Morton's own investigations have played a prominent part in relation to the work on vitamins A and D, and it is unfortunate that the relatively high price will prevent this book from finding its way into the hands of many biochemical research workers who would find much of interest and of value in its pages

The book is usefully illustrated by plates and figures, and a noteworthy feature is the table of carotenoids and their distinguishing properties The amazingly rapid progress now being made in the chemistry of the vitamins and hormones is responsible for the fact that some of the sections are already out of date to some extent Various phases in the application of spectroscopic methods are well brought out first, the uncertainty as to the significance of the absorption bands given by crude extracts, then the use of the characteristic spectrum in the concentration of the active principle, and finally, the application to the quantitative evaluation of the vitamin

The Statesman's Year-Book. Statistical and Historical Annual of the States of the World for the Year 1935 Edited by Dr. M. Epstein Seventy-second Annual Publication · Revised after Official Returns. Pp. xxxvi+1488 (London · Macmillan and Co., Ltd., 1935.) 20*s*. net.

THE new edition of this well-known book of reference maintains the familiar arrangement of past years, which gives rather more than a third of the book to the British Empire and the United States, and the remainder to the other States of the world with their Colonies and Dependencies, arranged in alphabetical order. The account of each State ends with a long list of useful books and there is a voluminous index to every place name. The volume has undergone the usual thorough revision and contains a marvellous array of recent statistical matter relating to area, population, finance and trade, besides ample accounts of constitutions and Governments Unsettled as the state of the world is at present, there have been no transferences of territory of importance except the Saar, no emergence of new States and no disappearance of old ones during the year. Manchuria still appears under its old name as a territory of China, although a coloured map shows Manchukuo according to Japanese sources A second coloured map shows the Saharan area ceded to Italy by the Anglo-Egyptian Sudan in the Libyan boundary settlement.

L'Espèce, la race, et le métissage en anthropologie introduction à l'étude de l'anthropologie générale. Par Henri Neuville (Archives de l'Institut de Paléontologie humaine, Mémoire 11) Pp iii+515. (Paris Masson et Cie, 1933) 200 francs

THE publication of an intensive study of 'race' and attendant problems is a new departure for the Institut de Paléontologie, which the author justifies by his views of its relationship to the objectives of the study of human palæontology and archæology M. Neuville's interpretation of the result of the geographical position of Europe and its function as a terminal point in racial migration is illuminating in relation to the consideration of the origin and distribution of racial characters in that continent

The most important section in this study of race, however, is that which covers the study of material relating to the crosses of different races, in which the valuable but not too well-known data from the French colonies of Annam and Tonquin and West Africa are set out and considered in some detail

A Text-Book of Quantitative Chemical Analysis By Dr A C. Cumming and Dr S A. Kay. Sixth edition, revised by F C. Guthrie and J T Nance. Pp xv+482 (London and Edinburgh. Gurney and Jackson, 1934) 15*s* net

ORIGINATING in 1913, this book has now reached its sixth edition—no better testimonial can be desired. The revision has been undertaken by Messrs. Guthrie and Nance, both lecturers in the University of Liverpool. Needless to say, the book has been brought up-to-date, for there is progress in this as in other branches of chemistry. Very properly 'ml' has been substituted for 'c.c.' The changes which are indicated in the preface include recent methods for calibrating volumetric apparatus and determining hydrion concentration The enhanced use of electrolytic methods is given due attention and the same applies to colorimetric methods, for which a number of new reagents have been described. In addition to what may be described as general analysis, the book has chapters relating to the analysis of ores and alloys, of gas and water.

Chemical Industry and Carl Duisberg

By PROF HENRY E ARMSTRONG, F R S

"ALAS, poor Yorrick! I knew him, Horatio: a fellow of infinite jest, of most excellent fancy" Geheimer Regierungsrat Carl Duisberg, honorary university senator, professor and doctor in all faculties, including theology, was born on September 29, 1861; he died on March 19, 1935 In telling his story, the history is told in large part of the most intricate and far-reaching of modern industries—also the history of an unparalleled advance, due wholly to the considered use of scientific endeavour by a nation, an advance involving incidentally a vast increase in man's knowledge of himself, of his power over himself and the world—all this the growth of only four fifths of a century! Curiously enough, the upgrowth of Germany as an industrial nation has been almost coincident with that of Japan Whilst, however, the constructive advance of Germany has been intellectual and original, the advance of Japan has been imitative and mechanical: she has given no evidence of any special intellectual advance, such as has been apparent in India, for example, in a remarkable development of mathematical physics It is, however, possible that we are too simple-minded to plumb her actions Being free from our Western traditions and prejudices, especially from our stubborn individuality, maybe the Japanese have fathomed the value of scientific method, indeed of method in general, as we certainly have not that consequently they are working to a clearly conceived plan If so, they will be very dangerous as rivals At least, they have the courage of their convictions and do things

At the moment, Germany is abandoning the method to which she owes her success: Is she to continue on the down grade or to recover her liberty of thought and action? Is Japan likely to advance sufficiently in intellectual power to sustain the great burden she has undertaken is this not already too heavy? May it not be that her arrogance comes from the fact that the old military element is regaining ascendancy? Having been a student in Germany before the war of 1870, having soon afterwards had as colleagues two of the men who shortly before had been instructors of the Japanese in our Western arts, I have long been more than an interested observer of the march of events. The one great point in favour of the Japanese is that they seem to be able to learn a lesson; our European characteristic is that we cannot and that our rulers are ascientific—playing dangerously only upon the credulity of the masses, without understanding the true state of affairs

By Carl Duisberg's death, Germany is deprived of one of the greatest and most valuable citizens she has ever had, in the legend of the future, he may well come to be considered the most efficient and effective industrialist the world has yet known—he played with consummate skill so varied a part, with such unusual forcefulness of character, clearness of understanding and breadth of outlook, ever with entire devotion to his country and to his chosen and beloved science The foundations of his success were certainly laid at the university, in Germany long the accustomed resort of the intelligent, including the upper commercial class—not the mere scholarship-fed, aimlessly competitive racing stables into which we have allowed ours to drift

The story of Duisberg's early career is profoundly interesting His father, a silk riband manufacturer and merchant, wished him to enter the business but he was attracted to chemistry while still at school Leaving properly early, he went to Gottingen, then to Jena. He had taken his degree when he was twenty, before the close of his sixth semester At Göttingen, he first came under Jannasch, who set him to work at complex analysis. In the second semester he was under Hubner, who used him to study the bromination of benzoic acid Finding, at the end of the year when he almost had a thesis ready, that he could not take a degree at Gottingen, as he had been at a non-classical *oberreal-schule*—moreover, that in any case he must continue his studies during four more semesters—he went to Jena. He most fortunately came under Geuther, long an assistant to the great Wöhler, the steadying philosophic influence in the Liebig-Wohler partnership Geuther was incensed when he learnt how Duisberg had been treated—that he had had no drill in preparation making He insisted on his going through a full course of disciplinary exercises, both inorganic and organic, in laboratory technique, making him work with the simplest means Eventually he gave him a theme for his doctorate—of course, dealing with aceto-acetic ether, of which Geuther (together with Frankland and Duppa) was the discoverer His chief subject was chemistry, with geology, mineralogy and national economy as secondaries—in choosing the last the child was father to the man

Having taken his degree, anxious to be independent of his father, without informing his teacher, Duisberg sought and obtained a post in the public food analytical laboratory at Crefeld Evidently seeing how great was his ability, Geuther

indignantly insisted that he must not so demean himself He had no assistantship vacant but made him his private assistant, according to Duisberg's own statement, in his obituary notice of Geuther (*Ber*, Oct 15, 1930), at the princely pay of 80 marks—instead of the usual 100—with a garret above the laboratory to live in In the book issued at the time of his seventieth birthday ("Carl Duisberg, ein deutscher Industrieller"), Duisberg is made to say that he was paid 1,000 marks, instead of the usual 1,200, plus the garret So is history written ! Geuther stipulated that he should not leave him until he obtained a suitable industrial post. The year must have been invaluable to him The curtain fell dramatically on the smash of glass ! Finding that no one would employ him until he was *militarfrei*, Duisberg decided to join up at Munich Geuther, when told of his intention, bitterly resented his leaving, insisting that he must keep his bargain The end came one day when, after angry discussion at his bench, Duisberg followed his master out of the laboratory brandishing in his face a large globular flask which he had been cleaning, eventually, as he reached the door, flinging this violently at his feet Repentance came at once Calling upon the Rector, he told him what had happened and that he feared Geuther would make it impossible for him to become an officer Evidently the Rector sympathised, as he advised him not to take the occurrence too seriously but to go to Munich. Such was the dramatic ending of his university career He left magnificently trained

At Munich, while serving as *Freiwilliger*, Duisberg worked in his spare time under von Pechmann, probably he was a little too lively for Baeyer. At the end of this year of military service, he was engaged, with two others, by Karl Rumpf, head of the Farbenfabriken vormals F Bayer & Co, Elberfeld Owing to the slump in alizarin, the firm was in queer street, paying nothing Rumpf gave his assistant his first real lesson in economics, teaching him that it was necessary to spend in order to earn The three young men were sent to different university laboratories, as no place could be found for them in the works. Duisberg went to Fittig's laboratory at Strassburg, history does not tell us what happened—they were very opposite characters. He began work on the synthesis of indigo, without result He then passed over to the study of azo-dyestuffs from benzidine and made orthotolidine, its next homologue At the end of a year, in the autumn of 1884, he entered the factory at Elberfeld, never to leave the firm except to translate it from a narrow, confined valley to a great open site at Leverkusen on the banks of the Rhine, taking no mean share of Rheingold treasure by so doing. He rose to gain for the firm a position as high as that attained to by any of its great rivals, moreover, not only to be its head but also the head of German chemical industry in general; in fact, he became a great man of affairs

Why is it that, with very few exceptions, our chemists insist on remaining public nobodies and play but an underground part in industry ? Duisberg was made by his university training, as not a few of his countrymen have been We cannot point to a single similar success of our ancient universities in constructional industry Can we doubt that the competitive, superficial, unimaginative training—mere knowledge worship—now given at these, following upon the neglect of all scientific training at our monastic, certificate-hunting public and other schools, is the main cause of our continued failure ? Notwithstanding the lesson we have had, our industry to-day is in no way efficiently officered. The Germans have known what *Lern* and *Lehr-freheit* are—their success has been due to the way in which their universities have been free institutions. Now they are being deprived of them Freedom is an unknown quantity to-day in our schools, half a dozen examiners control them all and make them pipe to one tune No experiment can be made Until and unless we place education under liberal, scientific control, until we displace the clerical type of mind by the practical, no progress will be possible for us We are doing nothing to develop and cultivate our innately practical intelligence, instead we are sterilising it by mere book worship In consequence of our training, our so-called science on the theoretical side is mere faith worship, dogmatic and doctrinal, not eternal doubt, no thought of public need behind it

Duisberg came upon the scene at a propitious time; the fates conspired to help him It is an interesting fact that his first technical work was inspired by a message from England—from a house-top in Burton-on-Trent, the roof laboratory of the chemist at Allsopp's brewery, Peter Griess, the father of diazo-chemistry and of the azo-dyestuff industry, in virtue of the work he did while assistant to the great Hofmann at the College of Chemistry, Oxford Street, afterwards at Burton-on-Trent, in amplification of the discovery which he had made when a student at Marburg Griess had submitted proposals to the Bayer firm for the preparation of certain benzidine sulphonic derivatives and their use in making azo-dyestuffs. The task was placed in Duisberg's hands to develop technically. Beginning at Strassburg, he continued the work when he joined the Elberfeld factory in September 1884. He soon succeeded where others less skilled had failed in preparing Griess's benzidine-sulphon-disulphonic

acid and in making from this a dyestuff for wool, *sulphonazurin*, which was patented in their joint names. Although this did not answer expectations, the way was prepared, as the Elberfeld atmosphere became charged with benzidine nuclei

On February 27, 1884, Paul Bottiger, up to the end of 1883 in the employ of the Bayer firm, patented the dyestuff which was to become known as Congo Red, the first dyestuff discovered with which it was possible to dye cotton directly I have reason to believe that Griess had previously made this and discussed its merits adversely with his friend Heinrich Caro, a leading member of the great Badische Anilin und Soda Fabrik, who, however, with Dr Martius, had gained his experience in dyestuff chemistry, in Manchester, with Roberts, Dale & Co Both the Badische and Duisberg's firm declined to purchase the patent Böttiger then offered it to Dr Martius's firm in Berlin Martius was also about to decline it, when a friend, a dyer, happened to call upon him and noticed the dyed samples upon his desk, being told of its properties, he displayed great interest in the dyestuff on account of its power of dyeing cotton directly.

The Berlin firm secured the patent and soon put the dyestuff upon the market as Congo Red It excited the greatest interest among dyers, although supersensitive to acids, because of its special behaviour to cotton. Bayers were naturally sore, and it is easy to imagine the chagrin of young Duisberg at having so high a trump taken out of his hand. He at once hoisted the Jolly Roger, which was to become the flag of the industry The dyestuff had two components A and B It was open to him to vary either He chose to vary A, benzidine, having already made its first homologue, ortho-tolidine Here he all but failed to recognise that he again held trumps In his first trials, he obtained only a brown mess, of no promise. He had the habit, however, of putting his beakers aside as he used them, clearing up only at the end of the week. When doing this, he noticed that the brown mess had turned into a scarlet Following up the clue, he discovered that the coupling of A and B took place only very slowly In thus discovering Benzopurpurin, he made the first effective, direct cotton dyeing dyestuff

A new field was doubly disclosed—up to that time no systematic use had been made of homologues On this account, much difficulty was experienced in securing a patent The Martius firm naturally objected to such a rival to Congo but in the end the two firms agreed to work together. Then a rival firm that had been cited for infringement of the Congo patent brought an action to invalidate the patent. In the end, all opposition was overcome and the patent declared valid largely through Duisberg's own enthusiastic pleadings before the expert court. His value to the firm was greatly enhanced through this. Benzopurpurin, being far less sensitive to acid than Congo Red, was a great commercial success In the second year of its manufacture, Duisberg's share of the profits was already 10,000 marks (£500), which he at once invested in the firm's shares

The effect of Duisberg's success was to stimulate, in an astounding degree, the development of systematic, scientific laboratory inquiry as chief objective of the industry The Bayer firm, under his enthusiastic guidance, may be said to have led the way Not only were new dyestuffs produced in endless variety of colour and shade, their use was also systematically studied in the dyeing laboratory The British dyers became mere tools of the German dyestuff makers, though lubrication with no little palm oil was needed to overcome their intense conservatism and rule of thumb methods

Duisberg had no little luck The opening up of the tetrazo-field involved a great extension of the range of synthetic dyestuff colour The diazo-colours previously on the market had been yellows and reds, Congo made from aminonaphthalene-suphonic acid was also red Substituting naphth*ol*-sulphonic acid for the naphthyl*amine* acid, so increasing the light absorbing power of the dyestuff, Duisberg obtained a blue but of an undesirable red shade He relates how, sleeping at home after lunch (he had not yet an orchard), he dreamt that if he were to displace the methyl in ortho-tolidine by methoxyl he would introduce a green shade and so obtain a blue akin to indigo. The dream came true He was beginning subconsciously to theorise about the conditions determining visible colour Accident was to carry him still further In manufacturing the dyestuff, large quantities of paranitrophenol were accumulated, this was put into casks and kept for a rainy day Various attempts were made to find a use for it, without success—until one day the news came that two medical men had been poisoned by a druggist mistakenly dispensing acetanilide for naphthalene This led to the recognition of the antipyretic value of acetanilide and to its sale by Kalle and Co as Antifebrin in large quantity Why not ethylate and reduce paranitrophenol, said Duisberg. He therefore had it converted into ethoxyacetanilide, phenacetin This proved to be even better than antifebrin. In undertaking the manufacture of phenacetin, together with that of sulphonal and trional, the firm embarked upon a new important branch of activity, in which they became leaders Aspirin followed in a remarkable

way Some genius in the firm, if not Duisberg, bodily lifted into a patent specification a paper in *Liebig's Annalen* describing the preparation and properties of acetylsalicylic acid Of course, the patent was lost when attacked in the Courts—but no matter The name *Aspirin*, which Duisberg had registered as a trade mark, still remained and gave the holders almost a monopoly What's in a name ? Everything ! Names are not all equally sweet The challenge to take an Aspirin is easily uttered—no one would think of asking for an Acetylsalicylic acid Duisberg always prided himself upon being a judge of 'technical effect', in no other case was this better shown

Gradually, as the firm prospered, Duisberg's productive activity as chemist gave way to a more general activity In 1900, he entered the directorate and became mainly occupied in erecting a great new works at Leverkusen, which in every particular bears witness to his creative ability He was particularly proud of the provision he made for the welfare of the workpeople After the War, he was largely occupied in the first place in organising the dyestuff industry, then German chemical industry as a whole—a task for which he was eminently suited by his masterful character, his great experience and above all his organising ability The appreciation showered upon him on the occasion of his seventieth birthday was overwhelming in extent and sincerity

Duisberg was much helped by Henry Böttinger, who had married into the firm before he entered it Up to the time of his majority, Bottinger had lived at Burton-on-Trent, where his father was chemist at Allsopp's brewery He was so entirely anglicised, that he spoke German as if he were thinking in English He took charge of the firm's external affairs and laid the foundation of their great success in Eastern markets I have a presentation copy of a tremendous quarto tome, beautifully got up entirely in the works, a lithographed reproduction in script of the letters Böttinger wrote home to his family during his travels in India and China He not only placed the firm's goods but also arranged for training centres in India at which instruction in dyeing was given to buyers of their dyestuffs. The use of native-grown vegetable dyes in the East was thereby greatly curtailed Now indigo is almost supplanted by synthetic indigotin, although if the industry were organised the natural dyestuff could be produced with advantage. Böttinger was so active-minded that later on he became a Member of Parliament Eventually, he was *veradelt*

I have sketched Duisberg's character more than once during the War, in *The Observer*; in *Chemistry and Industry* (March 27, 1931), apropos of an obituary notice of his great master Geuther which he had written for the German Chemical Society, recently (March 29) in *The Times* He must have been a lively youth When I first knew him, soon after he went to Elberfeld, in the first blush of his success, he was the perfect Gascon, filled with an astounding conceit—really this was his great asset So late as 1906, at our celebration of the jubilee of Perkin's discovery of the first aniline dyestuff, with complete unconcern and full belief in his words, he told us that we must regard Germans as God's own chemists, heaven sent beings with whom it would be absurd for the world to enter into competition Some of us smiled We had discussed our position and long lamented our commercial weakness Perkin, it is true, had been beaten from the field. Still, he had to his credit not only that he had made his discovery but had also started works by the time he was nineteen, without any Geuther to train him Later, he was the first in the field as the maker of alizarin Faraday, in 1825, had discovered benzene and analysed it accurately, even made the two naphthalenesulphonic acids out of which Teutonic chemists were to win fortunes, he had done not a little other chemical work Lancaster had bred a chemist in Frankland Personally, I had played to some effect with naphthalene and knew something of the colour game I did not despair of our some day again wearing the shoes we had cast off too early; I knew we had recruits in the background In fact, when Duisberg addressed us, the spirit was already at work in our Teutonic friends that made the late War inevitable. His own son, in saying "Good-bye" to my sons, in Lakeland, not very long before the War, expressed the hope that at no distant date he would meet them "on the field"; he even looked forward to becoming part owner of Derwentwater. This is sober fact The German is a complex character As chemists, it is essential for us to learn to dissect out the elements of his mentality Having spent nearly three years as a student in Germany before the War of 1870, I have been witness of some of his interactions Before '70, they were a primitive, almost pastoral, music-loving nation, wonderfully intelligent and absolutely indefatigable workers, asking only to be well led and ever willing to be led, almost child-like in their simplicity On the other hand, they were curiously lacking in sense of proportion and without humour, you had not far to go below the surface to meet with unpleasant if not barbaric reactions, such as Wagner has brought out most wonderfully in his tetralogy—such as the Red Queen saw in Alice: "A nasty vicious temper"

Duisberg had lacked the critical power, characteristic of his nation, to see sufficiently below the surface. He knew quite well that our failure was

mainly commercial and that our university system was greatly in fault He was too much overcome by his countrymen's overwhelming success in the industrial field , he did not see that no real attempt had been made by the world to meet their competition The world, in fact, had been hypnotised by Germany's ordered progress

Our action after the War was stupid We allowed lawyers to put themselves in charge These were followed by so-called business men We have yet to give technical knowledge and efficiency their due place This will ultimately be our sole chance of securing our proper share in the world's work Our recent partial success in re-establishing the dyestuff industry may largely be attributed to the example set by Mr James Morton, whose acute mind led him to surround himself with a picked band of competent workers and to accept their guidance unreservedly The outstanding service rendered by his chief assistant, the late Dr Thomas, has yet to be sufficiently recognised ; he was the nearest approach to a Duisberg we have had We have to take pains that we may breed such men—at present our schools are worthless for the purpose—indeed, they prevent them from arriving. If our industry is to prosper, we must abolish all clerical control of education and put it under men of scientific outlook—men who not only know something but also know how to use knowledge The present ignorance of the schools will never give us this. The future of the dyestuff industry will depend entirely upon the attitude of the public towards colour—upon the development of the colour sense The present world tendency is to abandon colour—everywhere black prevails an almost lost sense has to be recovered

Chemists belong to no nation the world over they are a community , one in spirit, in thought and in method, interdependent in their work. Eventually they must lead the world, as they alone can understand its operations The service Duisberg rendered was to the common good All can recognise the worth of the man, apart from his nationality , the value of the great example he set, apart from his technical service, by the exercise of a wide public activity and a wide philanthropy. Only by the aid of such men will the world eventually be sufficiently brought together in harmonious interrelationship

Quantum Mechanics as a Physical Theory

THE issue of the *Physical Review* dated May 15 contains a contribution by Prof A Einstein, B Podolsky and N Rosen under the title "Can Quantum - Mechanical Description of Physical Reality be Considered Complete ?" The authors answer this question in the negative They begin by pointing out that it is important to draw a distinction between the physical concepts, which are introduced into a theory and form its subject matter, and the objective reality, which is independent of the theory and which it is the purpose of the theory to describe. That is to say, we have to draw a distinction between the results of experiment and our theoretical description of them.

In order to test a theory the authors ask two questions . (1) Is the theory correct ? And (2), Is it complete ? The content of the paper is a consideration of the answers obtained when these questions are applied to quantum mechanics.

The first question can be answered in the affirmative if the theoretical conclusions agree with experiment. In physics, we test correctness by means of numerical values, and in this respect the authors have no adverse criticism to make of the quantum theory The second question is a more difficult one, and some explanation of its meaning is required before an answer can be attempted. A complete theory is understood to be one which provides a counterpart to each element of physical reality The definition of physical reality lies at the root of all that follows in the paper. The authors say If, without in any way disturbing a system, we can predict with certainty the value of a physical quantity, then there exists an element of physical reality corresponding to this physical quantity They accept this as a reasonable criterion They do not regard it as a necessary but as a sufficient condition of reality

Accepting this definition, the authors go on to show that the quantum-mechanical description of physical reality is not complete The first step in the argument is to show that the uncertainty principle places two alternatives before us Suppose that two physical quantities are represented in the theory of quantum mechanics by the operators A and B If these operators do not commute, that is, $AB \neq BA$, then the theory maintains that precise knowledge of one quantity is incompatible with precise knowledge of the other The best known example of this is that in which the physical quantities are the co-ordinate of position and the momentum of an electron We can only obtain precise knowledge of the second quantity by experiment, and in attempting this we destroy

our knowledge of the first. But both operators represent objects of physical reality, so that by the definition it must be concluded either that the theory does not contain concepts for both, that is, it is incomplete, or else the two quantities have not physical reality at the same time In quantum mechanics it is assumed that the wave function contains a complete description of this reality for the state to which it corresponds This is reasonable, since the information obtainable from this function corresponds exactly to that which can be predicted with certainty without altering the state of the system

In the final stage of the argument, an appeal is made to the process known as reduction of the wave packet. We must refer to the original paper for the details, but it is deduced that it is possible to predict with certainty two quantities corresponding to physical realities, and moreover that these quantities are represented by non-commuting operators. Thus we have to admit that if the quantum theory is complete and therefore contains concepts for these quantities then, although non-commuting, they correspond simultaneously to physical realities

We saw that the uncertainty principle presented us with two alternatives, and now we see that if we deny the first of these alternatives, we have also to deny the second The conclusion is that the first alternative, that the quantum theory is incomplete, has to be accepted

It is possible that the criticism does not strike at the root of the quantum theory, since so much depends upon a definition of physical reality, which is not of necessity included in the theory. If we could be satisfied that the definition is necessary or that without it two simultaneous conjugate physical quantities are represented by commuting variables, then the quantum theory fails. An interesting letter on this point from Prof. G Temple appears in NATURE of June 8 (p. 957).

The paper by Einstein and his collaborators is rather to be regarded as an appeal for a more direct description of the phenomena of physics. The authors seem to prefer the artists' portrayal of the landscape rather than a conventional representation of its detail by symbols which bear no relation to its form and colour. The expression of a belief that it is possible to provide a complete description of physical reality indicates the nature and purpose of the criticism. Presumably the appeal is for a replacement of the operator calculus of the quantum theory by a method of description which resembles that of the classical and relativistic theories in that, like them, it introduces concepts more directly corresponding to physical realities

In criticising quantum mechanics in this way, we must remember that it arose out of the inadequacy of existing models, and it has evolved in its particular way because it has had to do without them The theory has done what, in the face of difficulty, it set out to do It does not profess to describe actual phenomena but the possible results of measurements, and it is particularly concerned with the influence of the observer on the quantities observed Much work is being done at present on the notation of the quantum theory. There are difficulties to be removed and with their removal we may find that we have travelled in the direction desired by the three authors. Physicists can scarcely remain content with a situation in which the electron is an equation, and the remark sometimes heard that the school of quantum mechanics is content to establish itself merely as a bureau for ready reckoning is by no means true H T F.

U.S. Stratosphere Balloon *Explorer II*

A BRIEF reference was made in NATURE of February 23, p 299, to the remarkable preparations afoot in the United States to launch a new attempt in stratosphere research following on the mishap to *Explorer I* News has now come to hand that everything was ready by June 1 and the balloonists are only awaiting favourable weather conditions. The outstanding feature of this new experiment is the display of co-ordination of effort on the part of the National Geographic Society, the U.S. Army Air Corps and many of the public bodies interested in research. Capts. A. W. Stevens and O. A. Anderson will again ascend, and Capt. R. P. Williams is in charge of ground operations and has been named as alternative pilot.

Some idea of the magnitude of the task can be gained from the following details of the balloon and the experiments.

BALLOON

This was built and designed by the Goodyear Zeppelin Corporation, Ohio. When inflated it is 192 ft. in diameter and has a capacity of 3,700,000 cub ft and an area of 2⅔ acres. Its initial charge will be 300,000 cub ft. of helium, and with this 'bubble' of gas in it the top will rise 316 ft. from the ground when it is all complete and ready to start. The envelope is made of rubberised fabric, most of it weighing 5·3 oz. a square yard, at the top 7·2 oz. a square yard The gas can be released

by two pneumatically operated valves near the top and there are four inverted open canvas chimneys in the bottom, 7·5 ft in diameter and 17 ft. long, to relieve it of surplus gas when fully inflated by the reduction of the external pressure

The total lift of the balloon on the ground is more than 8 tons. This figure includes the weight of the balloon itself, men, equipment and ballast The gondola is 9 ft in diameter and weighs 638 lb empty It is painted white both inside and externally above the equatorial plane and black below. An arm, 14 ft long, extends horizontally from it carrying a fan on the end, which supplies a tangential force to rotate the whole balloon The gondola is provided with an 80 ft round point triangular parachute operated by a pilot parachute to draw it from its bag.

INSTRUMENTS AND EQUIPMENT

The bag is provided with a 3-ft. dial thermometer near the top to be viewed directly from the gondola through porthole and vent For cosmic ray studies, Prof. R A. Millikan has supplied three ionisation chambers, one exposed, one in two inches of lead and one, weighing 600 lb, in four inches of lead Dr W F G Swann has supplied counter sets for various elevations from the horizontal, a lead-shielded chamber for 'bursts' and a Wilson expansion chamber. Mr. O H Gish has supplied an apparatus consisting of a vertical chimney external to the gondola 1 ft. in diameter and 3 ft high for a continuous ion count of the external air. Sun, sky and earth brightness records will be taken from outside the gondola, and records made of temperature and barometric pressure with resistance thermometer and short mercurial barometer respectively. The readings of the latter will be further checked by vertical camera studies of the ground and transit circle observations of the balloon made from the ground

The sun and sky light will be studied spectrographically both from within and without the gondola for ozone content of the stratosphere. Mention has already been made of the vertical camera for height observations, but other cameras will photograph the horizon to obtain the figure of the earth, and a motion picture camera is provided to record any moving events Air samples will be taken and spores collected, and even cultures of fruit flies are to be exposed to the rigours of the stratosphere. Finally, the observers will be in continuous radio communication with the ground on a transmission of 13,050 kilocycles per second, and a study will be attempted of the diffraction by the horizon of two sets of modulated waves emitted from the gondola aerial at 56,000 kilocycles and 112,000 kilocycles a second respectively

News and Views

Retirement of Sir George Adam Smith

WHEN the autumn term begins, the Very Rev. Sir George Adam Smith will retire from the principalship of the University of Aberdeen. His long service of twenty-six years as principal exceeds that of any of his predecessors since the present University arose from the union of "The King's College" and "The Earl Marischal's College" on the passing of the first Universities Act of 1858. He has watched and guided the University during a period of notable development, when a demand for specialisation has increased the teaching staff by the addition of nine professorial chairs, three readerships, and forty-seven lectureships; and when these changes, together with an increase in the number of students from 1,007 to 1,272, have required considerable additions to the fabric of the University itself. Of equal importance for the future of education and of scientific research has been the formation of linkages binding the University as a working unit with other institutions. In the present year the former United Free Church College in Aberdeen has joined with the University, and co-operation of great promise for the development of biological investigation in the north takes place with the Rowett Institute for Research in Animal Nutrition, the Macaulay Institute for Soil Research, the Scientific Laboratory of the Fishery Board for Scotland, and the Torry Research Station In the course of another year a new and vital link between the teaching and clinical aspects of medical subjects will be completed at the new Infirmary These developments, on which, in some directions, the future of the University depends, Sir George has guided with a tact and balance of mind and with a friendliness and humanity which have endeared him to his fellow-workers in the University; and both town and University appreciate his services in ensuring that common appreciation, co-operation and goodwill unite the civic and academic interests of the community.

Valentin Magnan

THE eminent French psychiatrist, Valentin Jacques Joseph Magnan, the centenary of whose birth was celebrated on May 27 by a special meeting of the Société médico-psychologique, was born on March 16, 1835, at Perpignan, which was also the birthplace of three other celebrated French psychiatrists, Pinel, Esquirol and Falret. His medical education took place first at Lyons and then in Paris, where he

qualified in 1866 with a thesis on the anatomical lesions in general paralysis. The following year he was appointed physician to the Asile Sainte-Anne, to which he was attached for forty-five years. His most important work was concerned with the psychoses produced by alcoholism, in the modern investigation of which he was a pioneer, absinthe, in the prohibition of which in France he was mainly instrumental, and morphia; epilepsy, and sexual anomalies and aberrations. As director of Sainte-Anne, where he founded the Société clinique de médecine mentale, he was an enthusiastic advocate of the no restraint system and especially of the suppression of the straight-jacket. His clinical lectures, which attracted numerous French and foreign physicians to Sainte-Anne, were for thirty years published in *Le Progrès Médical*, of which the issue for June 8 commemorates the centenary. In 1893 he was elected a member of the French Academy of Medicine, of which he became president in 1915. In his will he left the sum of 25,000 francs to the Academy for the foundation of a prize in psychiatry which bears his name. His death took place on September 27, 1916, when he had reached the age of eighty-one years, his faculties remaining intact until the end.

Basutoland in Transition

FUNDAMENTAL changes in the life and economy of the natives of Basutoland are foreshadowed by the report (Cmd. 4907. H.M. Stationery Office) of the Commission, of which Sir Alan Pim is chairman, appointed by the Secretary of the Dominions to inquire into the financial and economic position of the country. The recommendations are drastic and affect almost every aspect of native life. The gravity of the financial situation, which dictated the appointment of the Committee in the first instance, shows no sign of alleviation, and even in the improbable contingency that the proposals are entirely set aside, the force of circumstances alone, it would seem, will bring about disastrous changes which will lead to the breakdown of native culture and the system of administration. The spirit of independence and pride of race characteristic of the Basuto people should be preserved at all costs as the essential condition of their future progress. Their spirit is explicitly recognised in the Report as a dominant factor in the problem of reform; but it is pointed out that, unless rightly directed, it may prove an obstacle in the way of advance towards the goal the Commission has in view—the creation of a real system of 'indirect rule'. In the multiplicity of topics discussed and of ameliorative measures suggested, this is the major issue. While the financial situation of the Protectorate has undoubtedly complicated its political future, the internal situation and the formulation of a settled administrative policy which will afford opportunity for the development and utilisation of the admittedly favourable traits in native character and culture must obviously be a prior consideration to that of the eventual transfer of responsibility to the Union of South Africa.

R.A.F. Big Flying Boat

THE performance figures of the *Saraband* built by Short Brothers of Rochester for the R.A.F., just divulged for the first time although the machine was built in 1932, show that it is by far the largest flying boat in the R.A.F. equipment, and is more powerful than even the German *D O X*. Its engines total 5,500 horse-power, maximum speed 150 miles an hour, climb 750 ft. a minute, with an air range of 1,450 miles, with full load. In this respect it is worth remembering that many countries make a practice of reporting performance trials with specially lightened loads. The machine has a wing span of 120 ft. and is 90 ft. long. It carries a military load of 5,960 lb., which includes an automatic pilot, the usual machine guns, and a 1½ in. automatic quick firer. The hull is a self-contained unit, containing sleeping accommodation for the crew, a workshop, a ward room, a drying compartment, an anchor winch, and gear for changing engines afloat. It is built entirely of steel and duralumin, and the hull design incorporates many novel structural features. A civil flying boat of the same size was under construction at the same time, but was stopped for reasons of economy.

Presentation of Prof. Piccard's Gondola to the Science Museum

ON June 12, the gondola of the balloon in which Prof. A. Piccard and M. Max Cosyns ascended into the stratosphere on August 18, 1932, was presented to the Science Museum, South Kensington, by M. Jean Willems, director of the Fonds National de la Recherche Scientifique, Brussels. His Excellency the Belgian Ambassador presided, and both Prof. Piccard and M. Cosyns were present. The gondola consists of an air-tight sphere (about 2 metres in diameter) of aluminium alloy, fitted with two manholes and several portholes, and equipped with various scientific instruments; it was attached to the hydrogen-filled balloon with which Prof. Piccard made his previous ascent on May 27, 1931. The second ascent, in 1932, was made from Dubendorf Aerodrome, near Zurich, and after a twelve-hour flight, the balloon landed safely in a field at Cavallaro di Monzambano, about ten miles south of Lake Garda. The maximum height reached during the voyage (determined trigonometrically) was 16,940 metres (10½ miles). The main objective of the flight was the investigation of cosmic radiations. Observations were made to ascertain the variation of intensity of these rays with height, and the distribution of the radiation in different directions was studied by means of a tubular Geiger counter.

Early Design for an Aeroplane

THE Science Museum, South Kensington, has just acquired through the generosity of Mr. P. A. Smith of Scarborough a small disc of silver about an inch in diameter bearing an engraved design for a flying machine which is remarkable in conception. The disc bears the initials 'G.C.' with the letter 'R' beneath and it is dated 1799. The reverse contains a diagram of forces relative to the design illustrated.

There is little doubt that it is the work of Sir George Cayley, Bart (1774–1857), who was the first to attempt to explain mathematically the fundamental principles of mechanical flight The flying machine represented is a manually propelled (assisted) glider It is a large monoplane, the plane being curved, with the operator sitting in a boat-shaped structure below and working by means of levers two large rectangular oars or paddles which were probably intended to function on the non-return valve principle by means of flaps An interesting feature is the combined rudder and elevator arrangement which consists of surfaces fixed at right angles to one another, the whole, it appears, universally pivoted—a device which has been attributed to Alphonse Penaud at a much later date Research is being undertaken to discover the full significance of the design, but the disc has been placed on exhibition

The National Physical Laboratory

THE report of the Laboratory for the year 1934 is a well-illustrated and indexed quarto volume of 260 pages. Each of the eight departments of the Laboratory gives a short account of its principal activities in an interesting and thoroughly readable form The increase in activity in industry has produced a corresponding increase in the work carried out by the Laboratory, particularly in that relating to shipbuilding, and it has been necessary to call for overtime and to increase the staff The movement for the abatement of noise has resulted in demands on the Sound Department from the Ministries of Health and of Transport. The deaths of Sir Arthur Schuster, Sir Horace Lamb, Sir Alfred Ewing and Dr. W. Rosenhain have deprived the Laboratory of four of its friends and supporters, but the changes of staff have been slight. The lectures on the work of the Laboratory given at a number of provincial centres have been much appreciated, and are to be continued. The new buildings for photometry will probably be brought into use this year, new high-speed wind tunnels are already in operation and the Lithgow installation for testing propeller blades will be available next year. The comparison of standards of measurement of all kinds with those of other countries has been continued with satisfactory results. The sound-isolating properties of walls and partitions of many types have been investigated and field tests of actual buildings can now be carried out. The work on refrigeration and preservation of food of all kinds has been continued for the Food Investigation Board, and that on protection from and dosage of X-rays and radium, for the Medical Research Council. The lubricating value of the oils derived from the distillation of coal is being investigated, and the production and working of the extremely light alloys of magnesium are being tested. Rapid advances are being made in our knowledge of the structure of the ionosphere, on which so many of the phenomena of wireless communication depend.

The Grand Coulee Dam

THE Columbia River in the United States is second in size only to the Mississippi. Owing to the fact that its source is high in a region of melting snows in the mountains of western Canada and Montana, its discharge is more continuous than that of all the arid regions of the west and the middle west combined. In an article in the *Scientific American* of April, Grace Kirkpatrick gives an interesting account of the Grand Coulee (Grand Valley) dam which engineers are now busily constructing. In prehistoric times the Columbia River, then much larger than it is to-day, was dammed by a glacier, and the torrents of water which poured through the high cliffs bordering the river flowed down and formed the Grand Coulee. The walls of the valley are in some places 1,000 feet high The upper 20 miles of the river are being closed with dams at each end to form a huge reservoir. The Columbia River sweeps across the State of Washington and forms for many miles the border between Washington and Oregon. On the plateau above its canyon-like banks are millions of arid acres known as the Columbia Basin which if suitably irrigated would be one of the most fertile lands in the world. The dam is being built in two units—the high dam and the low dam. The latter is exclusively a power development while the high dam will be used for power, irrigation, storage and navigation development The dam will raise the waters of the Columbia so that they can be pumped into the reservoir of the Grand Coulee and will then flow over the parched acres of the Columbia Basin The blocking of the river will create the largest artificial lake in the world. It is 151 miles long and will extend into Canada. The spillway in the centre of the high dam will be 1,800 feet long and no less than 325 feet high.

Costs of Electric Lighting since 1910

THE lowering of the cost of the electric light during the last twenty-five years, mainly due to scientific research and improved engineering methods, is fully appreciated by few. In 1910, carbon filament lamps, which had held the foremost place since the inception of the incandescent lamp, were rapidly being replaced by tantalum and tungsten lamps giving almost twice as much light for the same electric power. In the same year, by means of the new 'squirted' filament lamp, the light-giving efficiency was more than doubled. In 1912 the drawn tungsten filament nearly trebled the efficiency. All these lamps were vacuum lamps. In 1916 the invention of the gas-filled lamp trebled the efficiency, and the latest type of gas-filled lamp, the 'coiled coil' lamp, has nearly quadrupled the light efficiency, giving 11·25 lumens (approximately 0·9 candle) per watt. Many consumers are now getting their electric light at a cost of 0·5*d*. per unit who had to pay 6*d*. or more per unit in 1910. Electrical engineers and scientific workers may well be proud of lowering the cost to one fiftieth of what it was in 1910.

Metallurgical Research

THE lecture given by Dr. H. Moore, director of the British Non-Ferrous Metals Research Association, before the London Section of the Institute of Metals

on November 8, 1934, published in the March issue of the Institute's *Journal*, constituted an extremely valuable review of the more immediate past and future of metallurgical development. Under the title of "Recent Trends and Future Developments in Metallurgical Research", Dr. Moore surveyed the application of physical and physico-chemical methods to the study of metals and alloys, with particular reference to the industrial application of the results of research. In the period under review—the past decade—the output of metallurgical research has undoubtedly been unparalleled, but in Dr. Moore's view the main bulk of this large output has been concerned with the exploitation of fundamental concepts which had been developed more than ten years ago Research in progress at the present time is reviewed under six main heads. melting and solidification, working of metals, heat treatment, mechanical properties, corrosion, and electro-deposition, and the directions in which work may be expected to proceed in the near future are outlined. The impression gained from this exceptionally interesting and virile address is one of boundless fields of research, offering fascinating possibilities in the extension of the use of metals for a very wide range of purposes for the benefit of civilisation.

Science and Humanism

IN the quest for a unity underlying the rich variety of the universe, philosophers are in constant danger of limiting themselves to unreal abstractions and verbal dialectic. Both those who call themselves pragmatists, as dealing with things rather than with words, and those who prefer the fuller name of humanists, find that science, the most objective of human experiences, has a large contribution to make to our general body of thought. As is pointed out by A. Rey in "Les Mathématiques en Grèce" (*Actualités Scientifiques*, 217. Paris: Hermann et Cie., 1935) the study of the history of science may be recommended on two grounds. It may make scientific thought more accessible to philosophers, and may do something to break down, among scientific workers themselves, that narrow specialisation which is so prevalent to-day. Among the ancient Greeks, as also in the Renaissance, both ages of humanism and free inquiry, science had a considerable place, though not an exclusive one. The humanism of to-day has at its disposal an embarrassing array of tempting dishes; the difficulty is to make a well-balanced selection from them, and to get the whole range of mental vitamins without suffering from hyper-vitaminosis.

Description and Identification of Species

IN spite of the three quarters of a million species of animals which have been described binomially, it is remarkable how little there is of organised plan in the descriptions, taken as a whole. Some authors of new species are content with a few lines of characterisation, others seem to describe, not a species, but the total characters of an individual specimen. It is partly that species are not fixed, and that few writers, even on the same group, would agree upon the characters to be selected as criteria of specific rank, partly that the critical characters within different groups appear to be so diverse, that no common plan would fit more than a relatively few. Dr. Séverin Icard has made a bold attempt to standardise descriptions of species by advocating a method which he calls "la méthode des nombres signalétiques" (*Revue de Path. comp. Hyg. gen.*, Nov. 1934) It looks quite simple. Shortly, it is that, in regular order, parts of the specimen to be identified or described are examined, and the result for each part is represented by a number. The key to the parts to be examined for a particular group, and to the number corresponding to a particular character, say, legs yellow, is to be found in a set of "Tables de correspondance". Thus the special character of each part has its own particular number, a short-hand way of writing a description which normally would contain at least a few words for each part

Species Formula

IN describing a beetle, for example, Dr. Icard chooses seven characters, always read in the same order—colour of thorax, colour of elytra, form of thorax, form of elytra, form of feet and tarsi, form of antennæ, form of head. Each character, in a particular specimen, is represented by a number—the *nombre signalétique* or descriptive number, so that the total description of the specimen as regards specific characters may be represented by a series of numbers—the *formule signalétique* or specific formula. We wish to identify a beetle; we translate one by one its characters into the appropriate number; then having composed our specific formula we search for this particular formula in another book of words, "Le Répertoire général", and if we find the formula there we shall also find opposite it the name of the species which possesses this characteristic association of characters It is an attractive idea that the plant and animal worlds should be so completely tabulated that a set of symbols would identify any of their members, and if the method would enforce upon describers of species definiteness in characterisation and brevity, it might be well worth a trial.

Suggested Biological Survey for Union of South Africa

IN the *South African Journal of Science* (Nov. 1934, p. 396), Dr. R. Bigalke makes a plea for the inauguration of a biological survey in the Union. During 1911–33 the Provinces spent £607,674 in connexion with fish and game preservation and the destruction of vermin, and the suggestion is that a biological survey would furnish scientific information for the more efficient use of such expenditure. The survey would be a unit of the Department of Agriculture, and it would set in the forefront of its aims the solution of pressing economic problems, such as the biology and control of predatory animals, of noxious rodents, or rabies transmitters, and the relation of wild birds to agriculture. Before such

investigations had progressed far, the need for faunistic surveys would become obvious, and for the prosecution of these co-operation would be sought with the various museums. The author estimates that such a survey could be set going with a staff of not less than six biologists, who should have taken zoology as a major subject and botany and geology as minors. But can any thorough study of fauna be carried out without recourse to fairly thorough statistical analysis, and the author says nothing about mathematical qualifications

The Men of the Trees

THE tenth annual report of the Society of the Men of the Trees reviews the work of the past year, which has shown an increased membership of the Society, inaugurated by Mr. St Barbe Baker The work of the year has included lectures, meetings and exhibitions. Of the latter, the chief was the International Picture Exhibition, held at Grosvenor House, Park Lane, London, throughout November. Thirty-seven countries assisted the exhibition by sending tree paintings by some of their foremost living artists, and also treasures from the national collections. Several addresses were delivered at meetings by Ambassadors and Ministers accredited to Great Britain The opening address was given by Field Marshal Viscount Allenby, who dwelt upon the importance of forestry and tree-planting in Great Britain to make good the wastage of the late War Lord Allenby, even before the War was over in Palestine, had started to restore the land by tree-planting, a commencement which inspired the Men of the Trees to carry on the work. Before opening the exhibition, Lady Georgiana Mure pointed out that forestry and the care of trees is a world-wide thing and that we can "meet our friends from Overseas on a common ground of good fellowship, occasioned by the mutual admiration and love of the countryside and its chief ornament, trees". Mr. Baker directed attention to the advantage from an æsthetic point of view, as well as the hygienic and economic, of planting up the slagheaps in the Black Country of England, and stated that a part of the proceeds from the exhibition was to be devoted to that object.

Cereal Synonyms

THE Cereal Synonym Committee has come to a number of decisions on the stocks of cereals which it examined in 1934. In arriving at these decisions, the Committee was guided by the following definition of a cereal synonym: "The Cereal Synonym Committee regard two cereals as synonyms when they present precisely similar morphological characters, and when they also possess identical physiological characters in so far as they can be determined. Even then by this term they do not necessarily imply that these two varieties are of identical origin, though doubtless in the majority of cases they are. The possibility of two cereals of different parentage presenting such a close, if not complete similarity as to mask their individuality has not been lost sight of. But the Committee have to deal with facts as they are; they, therefore, regard as synonyms all cereals which are identical in the sense used above even when they know that the origins are different. Before the Committee come to a conclusion concerning the synonymity of any variety the breeder and/or the introducer is given an opportunity of demonstrating to the Committee such differences as he may claim to exist between his variety and the type variety." In compliance with the request of the Committee that as much publicity as possible should be given to its decisions, the National Institute of Agricultural Botany, Cambridge, has published a leaflet giving full details of the findings for the wheat, oats and barley varieties investigated.

Review of Agricultural Research

THE Royal Agricultural Society of England has recently issued its *Journal* for 1934, vol 95. As last year, "The Farmer's Guide to Agricultural Research" has been incorporated with the annual publication, so that it may be available to every member of the Society At the same time a number of copies are being bound separately for distribution to the Press and to centres of agricultural education and research. This valuable survey of recent scientific work has been carried out on the same lines as in previous years and the authors responsible for the various sections, namely, crops and plant breeding, diseases of animals, farm implements and machinery, farm economics, dairy farming and dairy work, the feeding of livestock, and soils and fertilisers, are the same as in 1932 The work dealt with is not limited to research conducted in the British Isles, but includes references to results achieved in any part of the world from which light may be thrown on the problems of British agriculture A few copies of previous issues (1925–32) are still available.

British Standard Specifications for Laboratory Glassware

IN further development of the work which is now being carried out by a committee of the Chemical Division of the British Standards Institution in the standardisation of laboratory ware including scientific glassware, British standard specifications have just been issued for graduated measuring cylinders, Crow receivers, Nessler cylinders and Petri dishes. Copies of the specifications (Nos. 604, 605, 612 and 611–1935 respectively) may be obtained from the Publications Department, British Standards Institution, 28, Victoria Street, London, S.W.1, price 2*s*. 2*d*. each post paid.

New Museum of Practical Geology, South Kensington

THE opening of the new Museum of Practical Geology, South Kensington, London, S.W.7, and the celebrations of the centenary of the Geological Survey of Great Britain, will take place on July 3–4. The opening ceremony will be performed by H.R.H the Duke of York on July 3 at 3 p.m. A preliminary account of the proceedings appeared in NATURE of March 23, p. 463. In the final programme now issued, it is announced that the director of the

Geological Survey, Sir John Flett, will deliver an address on July 4 on the history and functions of the Museum, in the lecture hall of the Victoria and Albert Museum. Several geological excursions have been arranged to follow the celebrations, and delegates will have the opportunity of studying, under expert guidance, the Isle of Wight and mainland opposite, the Wealden district, South Wales and Bristol, or Edinburgh and surrounding country. Further information can be obtained from the Director, Geological Survey of Great Britain, Museum of Practical Geology, South Kensington, London, S.W 7

Announcements

WE regret to announce the death, which occurred on June 14, at the age of seventy-six years, of Prof. J. B Cohen, F R S, emeritus professor of organic chemistry in the University of Leeds

THE following awards of the Royal Aeronautical Society have recently been made *Society's Silver Medal*, Mr. C C. Walker and Major F B Halford; *Simms Gold Medal*, Dr L Aitchison; *Taylor Gold Medal*, Mr F. Rodwell Banks; *Bush Memorial Prize*, Dr H Roxbee Cox

THE Trustees of the Lady Tata Memorial Fund announce that, on the recommendation of the Scientific Advisory Committee, they have made the following awards of scholarships and grants for the academic year 1935-36 These awards were open to suitably qualified persons of any nationality, for research work in diseases of the blood, with special reference to leukaemia *Scholarships* Dr M. C G. Israëls (Manchester), Dr. O Kaalund-Jörgensen (Aarhus). *Grants*: Prof W Bungeler (Danzig), Dr J Engelbreth-Holm (Copenhagen), Dr. Karl Hinsberg (Berlin), Dr Ch. Oberling (Paris), Prof Eugene Opie (New York), Dr. Lucy Wills (London).

A CONFERENCE on some aspects of the metallic state will be held in the H H Wills Physical Laboratory, University of Bristol, on July 2-5 One of the University halls of residence will be available for those attending the conference, and anyone wishing to have accommodation reserved there is requested to communicate with Prof. N F. Mott, H H. Wills Physical Laboratory, The University, Royal Fort, Bristol, 8.

IN connexion with the Noise Abatement Exhibition at the Science Museum, South Kensington, a conference at the Museum on June 26-28 has been arranged by the Anti-Noise League, 66 Victoria Street, S.W.1. The programme includes discussions on "Sound and Noise", to be opened by Dr. G. W. C. Kaye, of the National Physical Laboratory; on legal and housing aspects of noise; on the noise problem in relation to education; and on "Health and Noise", to be opened by Lord Horder.

IT has recently been decided by the Italian Ministerial Council that the participation of Italians in International Congresses should depend on Italian being made one of the official languages.

WE have received the commemoration number of the *Colliery Guardian and Journal of the Coal and Iron Trades*, which celebrates the 150th volume of that paper; as there are two volumes a year, this means that this paper has been issued for seventy-five years, no mean achievement for a technical paper The paper commences with a review of British coal mining during this period and with a brief account of the history of the journal since its formation. This is followed by a series of articles by various men well known in the colliery world for their eminence in the subjects which they have selected.

A PROSPECTUS has been circulated of the publication by Messrs McFarlane, Warde, McFarlane, of New York, of the illustrations of the "Anatomy of the Human Body", by Andreas Vesalius (1514-64). The drawings for this great work were made by John Stephen of Calcar in Cleves, a pupil of Titian. The book, a double crown folio (15 in. × 21¼ in), will contain all the illustrations of the "Fabrica" and "Epitome", 228 plates have been printed from the original blocks, 227 of which have been preserved in the University of Munich, with the descriptive Latin text The work is edited by Drs. Lambert and Malloch of New York, and Willy Wiegand of the Bremer Press, Munich. The subscription price is 100 dollars

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.—A head of the Mechanical and Civil Engineering Department in the Sunderland Technical College—The Chief Education Officer, Education Offices, 15 John Street, Sunderland (June 25). A district forest officer, and a district estate officer in the Forestry Commission—The Secretary, 9 Savile Row, London, W.1 (June 25). A lecturer in rural science and gardening in Bangor Normal College—The Registrar (June 28). A lecturer in mathematics and electrical transmission and distribution of power in the Derby Technical College, Green Lane, Derby—The Clerk to the Governors (June 29). A lecturer in engineering in Loughborough College—The Registrar (June 30). A lecturer in organic chemistry in University College, Exeter—The Registrar (July 1) A lecturer in agriculture and farm director in the Midland Agricultural College, Sutton Bonington, Loughborough—The Principal (July 2). A lecturer in agricultural chemistry and physics in the Swanley Horticultural College for Women, Swanley, Kent—The Principal (July 8). A professor of mining in the University of Leeds—The Registrar (July 8). An assistant in the Admiralty Technical Pool (electrical engineering)—The Secretary of the Admiralty (C.E. Branch), Whitehall, S.W.1 (July 13). A botanist at the Rubber Research Institute of Malaya—The Secretary, London Advisory Committee for Rubber Research (Ceylon and Malaya), Imperial Institute, S.W.7. A lecturer in civil engineering and building in the Portsmouth Municipal College—The Registrar.

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P 1042.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

What is a Colloid?

ASSOCIATION is the characteristic factor in the colloidal state.

Without it, no films, fibres, glasses, resins or plastics, no jellies, gels, liquid crystals, coagula or gelatinous precipitates, no high viscosity (Graham's colloidoscope), no opalescence, no colloidal particles built up of a myriad of ordinary atoms or molecules, no electrosmosis or streaming potential, no membrane equilibrium or any of the effects defined by Loeb as 'colloidal behaviour', no stabilising agents or protective action or sensitisation, no stability however transient of the great majority of colloidal particles which are dependent upon structural arrangement, not even the folding of the long chain molecules that gives the characteristic properties to such colloids as wool or rubber, none of the beautiful and varied architecture which utilises as building stones the colloidal particles, which are themselves products of association

In recent years there has been a tendency, particularly on the part of some who have been emphasising the immensely long chain structure of certain natural and synthetic colloids and their relation to viscosity in very dilute solution, to do away with the term micelle and to think only of the individual molecule as a single simple kinetic unit. However, since the convincing work of Sponsler, Dole, Meyer, Mark and Staudinger, no one now questions the long chain nature of such molecules as cellulose

Soaps are still recognised as association colloids, and the association of their molecules and ions is known to produce particles of orderly structure Yet this distinction is incompletely valid, for in dilute solution, to which Staudinger's formulations are confined, soaps are not colloids at all. As a matter of principle, in sufficient dilution in a suitable medium, all colloids are resolved into their molecular or ionic constituents, as happens with sols of WO_3 and V_2O_5 Few would care to deny association in higher concentrations, but are we to assume that in contrast to soaps or suspensions the association of long chain molecules is wholly disordered ?

Whereas in dilute solution simple sulphonic acids, as will be shown in a series of articles elsewhere, consist of ordinary molecules and ions, in concentrations above $N/10$ association is so predominant as wholly to submerge the influences discussed in the interionic attraction theory The result is that effects such as conductivity, freezing point lowering, and electromotive force increase instead of decreasing with concentration. Association must be of the cohesive van der Waals' type, emphasising the principle of 'like to like'.

When association is so predominant in such simple cases, it must be important in the behaviour of chain molecules, and indeed must be a factor always to be reckoned with in all solutions.

Raman Spectra of Deuterobenzenes and the Structure of Benzene

THE letter by Klit and Langseth in NATURE of June 8 (p 956), recording Raman frequencies of some deuterobenzenes, leads us to report our own results so far as these overlap, although we had wished to reserve publication until the problem of which these spectra supply only part of the answer had been fully solved Klit and Langseth record 8 lines for C_6D_6, and 1 for each of C_6H_5D and C_6HD_5 (not obtained pure). This note relates to C_6D_6 and C_6H_5D (both pure); we have not prepared C_6HD_5; we have, however, examined 1.4–$C_6H_4D_2$ and hope to study $1:3:5$–$C_6H_3D_3$ also, for the following reason

An acute problem concerning the structure of benzene was raised when Placzek showed[1] that the same fundamental frequencies cannot appear in both the Raman and infra-red spectra of molecules possessing a centre of symmetry. Bhagavantam[2] and Krishnamurti[3] had directed attention to several apparently coincident frequencies in these two spectra for benzene, and this seemed to show that benzene has not the plane regular hexagonal structure (point group D_{6h}) which the resonance theory requires. Various models of lower symmetry have been suggested by Placzek himself, and by Cabannes and Rousset[4], Deitz and Andrews[5], Weiler[6] and others One model of sufficient dissymmetry is the static Kékulé structure, but to revert to this would be retrograde on other grounds. The difficulty would disappear, however, if it could be shown that the coincidences are accidental, that is, that the identical or nearly identical frequencies depend in fact on different proper vibrations The problem is therefore to identify the proper vibrations, and this we shall do by measurement of the H–D displacements, first when the total symmetry of benzene is maintained as in C_6D_6, and secondly when different elements of symmetry are removed, as in $1.3:5$–$C_6H_3D_3$, 1.4–$C_6H_4D_2$ and C_6H_5D At present we are studying the Raman, infra-red and ultra-violet spectra of C_6D_6, $1:4$–$C_6H_4D_2$ and C_6H_5D.

(vii)	3064 (5)	2292 (5)	2292	3059 (10b)	—

Our Raman frequencies for C_6D_6 and C_6H_5D are in the accompanying table; approximate intensities are given in parenthesis, but not polarisations, as these measurements are not yet complete The

C_6D_6, m.p. 6·8°, was prepared by our sulphuric acid method[7], and the C_6H_5D, m.p. 5·5°, by the Grignard reaction. Klit and Langseth's frequencies (they do not record intensities) are added for comparison. The agreement is satisfactory, except for line (ii), which they find undisplaced in C_6D_6, whereas we observe a very striking shift. The self-consistent allocation of frequencies suggested below would have been impossible without this result. Frequencies are in cm.$^{-1}$.

No scheme of identification can be regarded as final which is based on only part of the evidence, but it is of interest that our C_6D_6 frequencies permit an allocation consistent with the symmetry D_{6h}. The proper vibrations of this benzene model have been formulated by E. B. Wilson[8], and Dr. E. Teller has given us the results of an equivalent calculation and of an unpublished theorem leading to frequency relations by means of which any assumed model may be tested. This theorem relates to the product, $\Pi_N \nu$, of the frequencies, ν, of any complete set of proper vibrations of like symmetry, N; it gives, indeed, the quotient, $\tau_N^{1,2} = (\Pi_N \nu)_1/(\Pi_N \nu)_2$, for any two compounds 1 and 2, which differ only isotopically with respect to one or more of their atoms.

The D_{6h} benzene model requires seven Raman fundamentals, divisible into three symmetry classes having distinctive relations between the tensor components, c_{ik}, of the change of polarisability (6-fold axis $= z$). Class A' ($c_{xx} = c_{yy}$, $c_{ik} = 0$) contains two totally symmetrical ('breathing') frequencies, one involving mainly C–H stretching, and the other C–C stretching. Class C'' ($c_{ii} = c_{xy} = 0$) has one degenerate vibration corresponding to C–H bending perpendicular to the ring. Class D' ($c_{xx} = -c_{yy}$, $c_{xi} = 0$) comprises four degenerate frequencies, one dependent mainly on C–H stretching, one on C–H bending, and two on ring deformation, all in the plane of the ring. Applied to C_6H_6 and C_6D_6, Teller's theorem gives $\tau_{A'}^{H,D} = 1·41$, $\tau_{C''}^{H,D} = 1·29$, $\tau_{D'}^{H,D} = 2·00$ (using distances C–C, 1·42, and C–H, 1·10 A.).

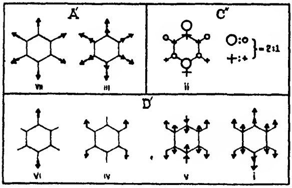

FIG. 1.

G. Placzek recognised the strong line (iii) as the C-ring 'breathing' vibration, and E. B. Wilson has suggested[9] that the doublet (v) arises from the accidental degeneracy of a fundamental with a combination tone. Our allocation is shown in the approximate graphical representation (Fig. 1). The symmetry classes are $A' =$ iii + vii, $C'' =$ ii and $D' =$ i + iv + v + vi, which gives $\tau_{A'}^{H,D} = 1·41$, $\tau_{C''}^{H,D} = 1·28$, $\tau_{D'}^{H,D} = 1·96$ (using the mean frequency of the doublet). Within classes A' and D' the separate approximate vibrations are allocated by means of the frequencies and the frequency shifts.

A New Nitrogen Afterglow Spectrum

IN a communication in these columns[1] I directed attention to the presence of two members of the Vegard-Kaplan system of nitrogen in the spectrum of the afterglow that was discovered by me in 1934[2]. Although very weak, the presence of these bands was the first direct proof of the existence of metastable molecules in active nitrogen. The spectrum of this afterglow was a very faithful reproduction of the auroral spectrum.

FIG. 1.

I have recently photographed the spectrum of the afterglow which is produced when the current is greatly diminished relative to that which produces the auroral afterglow. In fact, the current was so small that the discharge in the tube was barely visible. The spectrum of this afterglow is shown in Fig. 1, and it differs from the 1934 afterglow in the absence of the first-negative bands of N_2^+ and in the great enhancement of the relative intensity of the Vegard-Kaplan bands. The wave-lengths of some of the members of this system are marked on the bottom of the figure and those of the second-positive system on the top. When it is recalled that the Vegard-Kaplan system is emitted by the $A^3\Sigma$ metastable molecule, the remarkable nature of this spectrum is realised. The intensity of this system relative to the second-positive bands is much greater in this afterglow than in any other source so far observed, afterglow or discharge.

Several times recently I have offered the hypothesis that some of the radiations from the night sky agree closely with observed and predicted Vegard-Kaplan bands. The discovery of this new afterglow spectrum greatly favours that hypothesis. Also in its support is the great increase in relative intensity of the green auroral line when the current in the rapidly interrupted discharge is made equal to the one that produces this new afterglow. The relative intensity of the green line is increased at least by a

factor of ten over that reported by me[3] recently in these columns. It is suspected that most of the green line radiation in rapidly interrupted discharges arises in the afterglow, and further experiments are in progress in order to verify this fact.

Electronic Charge from de Broglie Wave-lengths of Electrons

WORK has been going on for some years at Uppsala for the purpose of increasing the accuracy of the determination of electron wave-lengths. A high-tension set has been arranged, with a special electron valve smoothing circuit taking up changes in input and output, and a tension regulating device including a standard cell, so as to give high tension accurately known and steady within 0·01 per cent Cathode rays from a hot filament, accelerated by this tension (V = 15–30 kv.) and passing through two narrow slits are diffracted by an etched galena crystal, giving rise to cross-grating diffraction patterns[1]. With this arrangement one gets very sharp spectral lines of different orders. The angles of diffraction can therefore be measured with great accuracy. From these data one can calculate the wave-lengths of the cathode rays with an error less than 0 1 per cent, the grating constant of galena being well known[2].

Using such wave-length values, one can make interesting calculations of several atomic constants. If, for example, we combine de Broglie's equation,

$$\lambda\sqrt{1+\frac{eV}{2m_ec^2}}=\frac{h}{\sqrt{2em_eV}}=\lambda',$$

with the expression for the Rydberg constant,

$$R=\frac{2\pi^2e^4m_e}{ch^3},$$

we obtain for the calculation of the electronic charge

$$e=\text{const.}\,\frac{V^{3/4}\,\lambda'^{3/2}}{\sqrt[4]{e/m_e}}.$$

R is known from spectroscopic measurements with very great accuracy, and e/m_e is fairly well known and enters the formula in the power 1/4 Thus, we can hope to find e with an accuracy sufficient to enable us to choose between oil drop and X-ray values of e.

Preliminary measurements give $e = (4{\cdot}796 \pm 0{\cdot}010) \times 10^{-10}$ E.S.U.

The work is proceeding and a definite and detailed report will shortly be published elsewhere.

A Search for the Extreme Infra-Red Spectrum of the Sun

THE solar spectrum in the infra-red has been thoroughly investigated throughout the range of wave-lengths up to about 11 μ Radiation of longer wave-length is practically completely absorbed, chiefly by the water vapour present in the atmosphere According to E. von Bahr[1], there are reasons to expect, from theoretical considerations, that for wave-lengths greater than *ca* 400 μ, water vapour will be again transparent. In 1914 Rubens and Schwarzschild[2] made an attempt at the Astrophysical Observatory at Potsdam to measure the intensity of solar radiation in this region of the spectrum by using the quartz lens method for isolating it, but the intensity proved too small to be detected even by means of the very sensitive instrument they used

On the suggestion of Prof M A Lewitsky, we made a similar attempt last summer in the exceptionally clear atmosphere of the southern slopes of Mount Elbruz (Caucasus) at an altitude of 3,000 m. above sea-level. For isolating the extreme infra-red radiation, we used two sheets of black paper placed in front of a metal mirror 60 cm in diameter, this focused the radiation transmitted through the paper on to one group of junctions of a differential surface thermopile, which was used in order to minimise the otherwise very considerable influence of stray radiation and changes of temperature The thermo-current was measured by means of a photo-relay similar in design to that described by Bergmann[3]. For illuminating the differential photo-cell of this relay we used a heliostat

The apparatus proved so sensitive as to enable us to record one tenth of the radiation that was to be expected according to Planck's law for the region beyond 400 μ, that is, the only region of wave-lengths likely to pass through the water vapour of atmosphere, two sheets of black paper and a quartz window, 2 mm. in thickness, of the thermopile

Since the layer of the atmosphere below 3,000 m holds about five-sixths of the total amount of water vapour contained in the atmosphere, we may take it that, so far as the absorption of the sun's rays by water vapour is concerned, the conditions of our experiment were about five times as favourable as those of Rubens and Schwarzschild, who worked at low altitude and in a contaminated atmosphere. On the other hand, the sensitivity of their apparatus was about twice as great as that possible with our apparatus in the open air Although we had thus, on the whole, somewhat better conditions than they, we also were unable to detect any trace of radiation from the sun in the extreme infra-red.

A detailed description of our experiment will be published elsewhere.

Philosophy and Modern Science

IT is disconcerting to find how rarely physical scientists trouble to make themselves familiar with the results of recent psychological investigation, even those results of the more important and far-reaching

kind While the psychologist is well-nigh constrained to follow, in a general way at least, the progress of physical inquiry, the physicist, when he ventures into the psychological field, almost invariably has recourse to a number of obsolete ideas, ideas which have long since been discarded by psychologists themselves

What, for example, does Dr. Jeffreys mean by the term "sensation", which he uses so freely in his letter under the above heading in NATURE of June 1? Does he mean the mental act or process of *sensing* (more properly, the mental act or process of perceiving), or does he mean *that which is sensed* (or perceived), what it is now usual to call the *sensum*? If he means the former, then certainly "each sensation is private to one individual"; but, in that case, "we cannot," as Dr. Dingle says, "speak of observing sensations", not at all events in the way Dr Jeffreys implies, because, as Dr. Dingle puts it, the "sensation" is the observing and "not a thing to be observed" If Dr. Jeffreys means the latter, then no doubt a sensation can be observed, but, in that case, it is sheer dogmatism to assert that sensations "obviously do not exist when they are not observed" That is by no means obvious, on the contrary, I imagine most modern psychologists would agree with Stout that sense-qualities, such as colours and sounds, "do essentially enter into the constitution of the material world" It requires, indeed, but little reflexion to see that what Dr Dingle calls a "sensation of whiteness" (that is to say, the awareness of whiteness) is not itself white, any more than the apprehension of a triangle is itself triangular

There is corresponding confusion in the use of the term "concept" It is, of course, impossible here to discuss in detail the nature of concepts, but briefly a concept may, psychologically considered, be said to be a way in which universals are cognised. Clearly, however, neither a ghost nor the planet Neptune (referred to in the correspondence in question) can be said to be either a universal or a concept, each is no less individual and particular than a patch of blue or a sound Nor is it in the least degree true to say that what are sensations to one person are concepts to another person. I take it that by "concepts" the writer means, in this context, what are usually called "images"; and that he intends to assert that what one person is sensing another person can only imagine. Even that, however, is far from obvious, and cannot be laid down as an indisputable truth.

G. DAWES HICKS.

9, Cranmer Road,
Cambridge.
June 4.

OTHERS beside Prof Dingle find this discussion "amusing"[1]. Each disputant is trying to show that only his philosophy is compatible with science, if he succeeded, he would surely destroy the object of his attempt. For the distinctive feature of scientific propositions, and presumably the source of their evidential value, is that they can be believed by anyone, whatever his philosophy

Of course, this agreement may be illusory. Profs Dingle and Levy, who have such strong and such divergent views about the "external world", may be assenting to entirely different propositions when they both assent to (say) Ohm's law. But then there is no science for them to quarrel about. If they are assenting to the same proposition, surely their first step should be to find out what this proposition is. Of course, they will never agree as to why they agree; but they might agree as to what they are agreeing about. They will never achieve even that, while they insist in dragging in conceptions, such as reality and existence, that lie at the very core of their differences.

NORMAN R. CAMPBELL.

June 3.

[1] NATURE, 135, 912, June 1, 1935

IT does not seem to have occurred to the parties to this controversy that it is based, like so many controversies, on a difference of definition of terms. Prof. Dingle describes the method of science and defines the "logical network" resulting as the "external world" Others might prefer the term "scientific world" or the "scientific picture of the external world". To Prof. Levy the "external world" is what the man of science studies, to Prof. Dingle the result of these studies So we have words, words, words!

In his letter in NATURE of May 25, Prof. Levy describes two schools of thought, and by so doing implies that they are antithetic One "claims that science is an historical phenomenon produced by human beings in their handling of the world of which they are parts, a social practice . . ."; the other school sees science "as the organisation of our experiences in logical form" I belong to both these schools and see no inconsistency in doing so I do not, however, accept Prof Levy's corollary to his description of his first school that the man of science should be responsible for the social consequences of his work Were such a doctrine to be acted upon, a scientific laboratory would become an arena for the disputes of ethical teachers and party politicians!

Social Research

THE leading article on "Road Traffic Research" in NATURE of April 13 directs attention once again to the need for scientific research into social problems, for which I contended in my communication in NATURE of December 9 (p. 898). The present very unsatisfactory condition of road traffic is but another instance of Government action in a matter of which those responsible have an inadequate knowledge. As is stated in NATURE of April 13, "The tragic position of the road traffic problem at the moment and the sterility of all attempts to diminish accidents, whether by motor control, registration, insuring, licensing or deterrent enactments, are due primarily to the omission to base legislation on scientific experiments and definite facts. In the absence of such study, well-intentioned legislation is apt to have consequences and repercussions widely different from or even opposed to those for which it was designed"

This passage emphasises the same need with regard to road traffic problems that my communication emphasised with regard to industrial problems generally, the need, that is, that there should be no legislation on industrial problems unless it is based on carefully ascertained facts, and not only facts concerning the industries themselves, but also (what is at least as important) those showing what previous

legislation has effected. The fact that there has been more industrial legislation in Great Britain during recent years than ever before in our history, and that our industries, instead of being better, are worse now than before, is in itself a proof that investigation is urgently needed. "The acquisition of data is the first necessity." From the study of these data there must gradually emerge principles of guidance in legislative matters of which we are in sore need: no greater benefit can be conferred by science on humanity at large than the discovery of these principles. It can scarcely be hoped that legislation will be on right lines in the absence of this guidance, which science alone can provide.

Let it not be forgotten that our civilisation (of which industry is the main support) has been built up by our forefathers and handed on to us as a precious heritage, and it is our first duty to posterity to see that it does not suffer while under our charge, but is passed on to those who will come after us in a condition somewhat better than that in which we received it; to do less than this we should be guilty of breach of a great trust. We are apt to boast of the great advance made by science, but what will be the verdict of the historian of the far future when, in recounting the history of the critical times through which we are now passing, and in view of later disasters, he makes the astonishing discovery that our legislation was framed without scientific guidance of any kind; that while it has occupied itself with the changes and movements taking place in stars and nebulæ millions of light years away, which can affect our civilisation not at all, it neglected those taking place on our doorsteps on which our very existence depended?

Essential Structural Discontinuities in Certain Adsorbed Films

IN connexion with some recent experimental work, it has been necessary to consider in detail the process of building up an adsorbed film which is formed by the adsorption on neighbouring solid atoms of the two atoms of a diatomic gas molecule, and in which the adsorbed atoms are immobile and stable. Such a film is necessarily imperfect and incomplete, having gaps or holes in it.

For the sake of definiteness, let us consider adsorption on a plane in which each surface atom is surrounded by four equally spaced other atoms. As the film is gradually built up, certain single surface atoms will find themselves surrounded by four filled places. Such atoms will be able to take no part in the adsorption process and will remain bare. The complete film thus of necessity has a sort of irregular mosaic structure.

It is important to know what proportion of the surface atoms remain bare. To do this an experimental numerical test has been carried out in which neighbouring pairs of points on a diagram of such a plane have been selected at random and occupied. It was found that about eight per cent of the total number of surface atoms remain uncovered. In order to test whether the particular assumption about the atomic arrangement is of importance, a similar test was carried out on a hexagonal arrangement, so that there could be six possible places for the second atom of a molecule to occupy. The numerical result was practically identical.

The actual case under consideration was that of oxygen on tungsten, and experimental evidence for the existence of these gaps has been obtained. The uncovered surface atoms will undoubtedly exert a much greater attraction on impinging oxygen molecules than the other parts of the surface. An adsorbed film of molecular oxygen has been found of the right amount to correspond to adsorption on these gaps in the atomic film.

For the adsorption of molecular oxygen, these gaps must be regarded as active parts of the surface. They would probably also be centres of catalytic activity if one were using a surface from which the atomic film had not been removed. If they were, an amount of oxygen small compared with that required to cover the surface completely would be sufficient to poison it.

A full account of experimental methods and their application to the study of these films is ready for publication, together with a discussion of other properties of the gaps.

In conclusion, it may be pointed out that almost any immobile adsorbed film, except one formed by the adsorption of gas molecules on neighbouring surface atoms without dissociation, will have essential irregularities of a similar type.

Lattice Distortion in Nickel-Iron

RECENT investigations of W. A. Wood[1] on the broadening of high-order Debye-Scherrer lines of copper and α-brass have shown that the lattice distortion may be accompanied by changes in the spacings of various lattice-planes, pointing to a change in shape and (perhaps) size of the unit cell. The occurrence of such an effect can be very clearly shown for nickel-iron. For an alloy with 53 atomic per cent Fe, the side-length of the unit-cube a is 3·58 A., so that the (400)-reflections with cobalt $K\alpha_1$ and $K\alpha_2$ radiation occur at about 85° and 87°

a *b* *c* *d*

FIG. 1. Nickel-iron (400)-reflection, cobalt $K\alpha_1\alpha_2$ doublet.
a, annealed band.
b, after 10 per cent compression perpendicular to plane of rolling.
c, „ 2 „ stretching parallel to direction of rolling.
d, „ 2 „ „ at 45° „ „ „ „

respectively, and thus show extremely large dispersion (the distance of the α_1 α_2-lines for a specimen to film distance of 12 cm. being about 7 mm.). Back-reflection photographs of discs, cut from recrystallised cold-rolled band, show these reflections with great intensity, as the recrystallisation texture is a very pronounced 'cube-texture' ('Würfellage'), all crystals lying with a cube-face and -side within ± 10° parallel to the plane and direction of rolling[2]. The effect of compression-deformation is shown in Fig. 1,

where a relates to the original disc, b to the same disc after compressing it to about 10 per cent (the discs were rotated about an axis parallel to the X-ray beam) The shift of the $\alpha_1\alpha_2$-lines amounts to about one sixth of their distance apart, corresponding to a *decrease* in spacing of about 0·04 per cent

Wood observed that the rate of broadening of lines from different planes differed likewise[1]. A directional effect was also observed in our case in the sense that the degree of lattice distortion of a definite plane is dependent on the relative orientation of crystal lattice and direction of deformation ; for this experiment, strips of the recrystallised band were stretched by about 2 per cent parallel (Fig 1c) and at 45° (Fig. 1d) to the direction of rolling, that is, nearly parallel to a [100]- and a [110]-direction respectively The severe distortion in the second case might perhaps be related to the fact, found for aluminium, that crystals stretched in that direction exhibit an extremely pronounced recrystallisation power[4]

In conclusion, I wish to thank Mr F M. Jacobs for his help in taking the photographs

Lattice Parameters of Solid Solutions in Silver

IN continuation of work on valency effects in alloys, I have recently measured the lattice parameters of the primary solid solutions in silver formed by the elements cadmium, indium, tin and antimony, which follow immediately after silver in the Periodic Table. This work has led to the discovery that in dilute solid-solutions of these elements, the alloys of the same equivalent composition have identical lattice parameters By the term equivalent composition is meant the atomic percentage of the solute element multiplied by its valency, and the above relation implies that if the lattice parameters of the alloys are plotted against the equivalent compositions, the points for all of the four alloy-systems lie on a single curve. Alternatively, it may be said that the initial expansion of the silver lattice produced by one atom of the above elements is proportional to the valency.

The relation is thus of the same type as that previously found for the depression of freezing point of silver by the same elements, and may perhaps indicate an effect proportional to the repulsion between a solute and a solvent ion.

Dipole Moments of Ethyl and Phenyl Isocyanates

THE dipole moments[1] and the Raman spectra[2] indicate that the isothiocyanate group, $-N=C=S$, is linear. The isocyanates are now found to resemble the isothiocyanates. The Raman spectra indicate that the group $-N=C=O$ in the isocyanic esters is linear[3], and this conclusion agrees with inferences drawn from the dipole moments.

Ethyl and phenyl isocyanates we find to have moments of 2·81 D and 2·28 D respectively. No other value for the ethyl compound is available, but the published results for phenyl isocyanate are 2·34 D at 18° in benzene[4] and 2·23 D at 25° in carbon tetrachloride[5], the mean being 2·28 D.

The difference between the moments of the corresponding isothiocyanate and isocyanate gives the value of the excess of the $C=S$ over the $C=O$ moment. This difference deduced from other compounds is given below.

Ethyl isothiocyanate	3·31	0 50	Phenyl isothiocyanate	3 00	0 72
Ethyl isocyanate	2 81		Phenyl isocyanate	2·28	
Thiobenzophenone	3 37	0 42	Dianisyl thioketone	4 44	0 54
Benzophenone	2 95		Dianisyl ketone	3·90	

Bergmann has published two values of the moment of phenyl isothiocyanate, namely[6], 2·76 D and[4] 3·00 D, and it will be seen that the former value exceeds the moment of phenyl isocyanate by 0 48 D The other figures are in satisfactory agreement with each other

The solvent used in the present experiment was benzene, and measurements were at 20°. Ethyl isocyanate, prepared from potassium ethyl sulphate and potassium cyanate, was twice fractionated, dried by sodium sulphate and refractionated. The moment was measured immediately. The physical constants were boiling point, 59·8°/759 mm ; d_4^{20} 0·9031 , n_D^{20} 1·3808. Phenyl isocyanate from Kahlbaum was dried and fractionated . boiling point, 161·7°/752 mm. ; d_4^{20} 1·0946 ; n_D^{20} 1 5363.

	P_{∞}	P_E	μ
Ethyl isocyanate	185 c c	18 8 c c.	2 81 D
Phenyl isocyanate	144 c c	33 9 c c	2 28 D

The details of these results and those for analogous compounds will shortly be published.

Interchange of Heavy Atoms in Organo-Metallic Compounds

THE interchange of heavy atoms in organo-metallic compounds, reported by Mrs Leigh-Smith and Dr. Richardson[1], using the radioactive indicator method, is in line with work done by Hilpert and Grüttner[2], who, however, found evidence of detachment of the organic radicals from the metal. They found that a reversible reaction took place between mercury diphenyl and metallic bismuth, with formation of a little diphenyl, at 250° in hydrogen.

When working on alkyl bismuth compounds under the direction of Prof. W J. Jones at Cardiff, I attempted to prepare mixed alkyl-bismuthines, and obtained results indicating some looseness of binding between the bismuth atom and the alkyl residues. On treating amyl bismuth dichloride with ethyl magnesium bromide, triethylbismuthine and tri-n-amyl-bismuthine were obtained in addition to n-amyl-diethyl-bismuthine. Challenger[3] obtained similar results with ethyl magnesium bromide and

diphenyl-bromobismuthine, suggesting that organic radicals are readily liberated from their compounds with bismuth.

Exchange of metal atoms will probably occur with many typical organo-metallic compounds, where the link between carbon and metal is weaker than that between carbon and a non-metal of the same group of the Periodic Table; also, the strength of binding decreases with increasing atomic weight of the central atom.

Synthesis of Dehydroandrosterone by the Decomposition of γ-Sitosterol from Soya Beans

Two substances have been isolated from the urine of men which resemble the male hormone in their ability to stimulate the growth of the capon's comb[1]. One of these, androsterone, described in detail by Butenandt and Tscherning[2], has been produced artificially by Ruzicka and his collaborators[3] by means of the oxidative decomposition of epi-dihydrocholesterol acetate, and has thereby been recognised as 3-epi-oxy-allo-ætio-cholanone-(17). A second oxyketone containing two hydrogen atoms less has been obtained by Butenandt and Dannenbaum[4] from an unsaturated chloroketone, $C_{19}H_{27}OCl$, occurring in extracts of urine, by replacement of the chlorine atom by a hydroxyl group. On carrying out the analogous replacement reaction using the saturated chloroketone, androsterone was obtained. These reactions leave the question unanswered as to the position of the double bond and the steric position of the hydroxyl group.

I have elucidated this by carrying out the synthesis of the hormone by means of the decomposition of one of the known sterols. Acetylated sitosterol obtained from soya beans was chlorinated in the 5,6-position in order to protect the double bond, and the side chain was afterwards removed by vigorous oxidation with chromic acid, more or less according to the classical method of Ruzicka by which the identity of the ring system of sitosterol and cholesterol has been determined[5]. From the dechlorinated and saponified reaction mixture, a sparingly soluble semicarbazone was obtained; this, after hydrolysis, gave beautiful crystals of an oxyketone which proved to be chemically and physiologically identical with dehydroandrosterone obtained from urine in this laboratory. This oxyketone has a melting point at 147°–148° C. (corr.), the mixed melting point with dehydroandrosterone showing no depression; oxime, leaflets or needles, melting point and mixed m.p. 190° C. (corr.); benzoate, melting point 252°–253° C (corr.); specific rotation, + 13·5° in absolute alcohol. The capon unit is about 210γ, which is the same as the dose required of natural dehydroandrosterone (androsterone = 70γ). Dehydroandrosterone is therefore 3-oxy-Δ-5-6-ætiocholenone-(17).

This configuration of the ring system is similar to that of sitosterol and cholesterol, which is interesting in as much as it has been found possible, by a modification of the existing process (K. David[6]) to prepare, in this laboratory, dehydroandrosterone from urine in almost the same quantity as androsterone.

The details of this work will be published elsewhere.

Selective Accumulation of Lipochrome

IT is well known that different animals deal with carotenoids derived from vegetable sources in various ways. The adipose tissue of the horse and the cow contain considerable amounts of polyene-hydrocarbons (carotenes), but it does not accumulate polyene-alcohols (xanthophylls). A precisely opposite selection would appear to take place in the fat of the hen.

We tried to locate the organ in which this selection takes place and chose the horse for the following experiment. The blood serum of the horse is free from xanthophyll, and therefore the elimination of this carotenoid takes place before it enters the general circulation. So the question arises, whether the polyene-alcohols are not absorbed at all by the gut, or whether they reach the liver and are transformed or eliminated there. To choose between these alternatives, we took blood samples, therefore, while absorption of large amounts of green food was going on, from the portal vein of a narcotised horse. No xanthophyll was found in the serum, the lipochrome of which was identical with that taken from the jugular vein; but the carotene content was found to be increased.

This observation makes it quite probable that xanthophylls do not cross the wall of the gut and that selection already takes place in the digestive organs of the horse.

Keratin Digestion in the Larvæ of the Clothes Moth

THE digestion of keratin in the larvæ of the ordinary clothes moth, *Tineola bisselliella*, was investigated by means of the micro-methods developed by Linderstrøm-Lang and Holter. In the secretion of the middle intestine a powerful proteinase was found having a pH optimum about 9·3 (40°, splitting up casein) and, contrary to animal trypsin-kinase, being but little sensitive to addition of thiol compounds (sodium sulphide, sodium thioglycolate). The pH of the secretion of animals fed with wool was about 10 (measured with the glass electrode in a carbon dioxide free chamber) and gave a strong nitroprusside reaction which was most clearly visible in the half-digested hairs present as contamination in the secretion. The reaction disappeared soon after the secretion had been exposed to the air; only a very small further visible change of the hairs was

observable when the secretion (with half-digested hairs) was kept in a moist chamber after removal from the intestine. Animals fed with cotton wool or filter-paper (made inviting to the animal by covering it with a thin film of casein and wool-fat) gave scarcely any nitroprusside reaction, but the reaction reappeared when cystin was added to this food (although this is left quite undigested by the animal).

It was therefore assumed that the secretion contains an agent capable of reducing the S – S bonds in the hair (see Astbury[1] and Speakman[2], Goddard and Michaelis[3]) but auto-oxidisable in the air. The reduction of the hair keratin opens its peptide chains to the attack of the proteinase (Goddard and Michaelis) the activity of which is but little influenced by the low oxidation-reduction potential of the medium. The nature of the reducing agent is unknown. It is not a thiol compound. Its reducing power may be estimated from the accompanying table, which records some experiments on the reduction of certain dyes in the middle intestine (see also Titschack[4]).

Dye	E_h at pH 10	Animals fed with wool stained with dyes SH + (Reducing agent having reacted with S – S)	Animals fed with cotton wool stained with dyes SH – ("Pure reducing agent")
Methylene blue	– 0 08	reduced	reduced
Indigo tetrasulphonate	– 0 13	,,	,,
Indigo disulphonate	– 0 22	partly reduced	partly reduced
Gallophenine	– 0 29	,,	,,
Brilliant alizarine blue	– 0 34	not reduced	not reduced
Rosinduline GG	– 0 44	,,	,,

Experiments on the digestion of sheep wool by the moth proteinase *in vitro* using sodium thioglycolate as reducing agent at pH 10 (Goddard, Michaelis) showed a rapid splitting-up of the wool with formation of equivalent quantities of amino and carboxylic groups. Under the same conditions pancreatic trypsin-kinase with the same activity towards casein had no effect, due to inhibition by the thiol compounds.

The experiments are being continued.

Mechanism of Respiration

IN a previous letter[1], I discussed the respiration of the minced breast muscle of the pigeon. In this material succinic acid seems to play by its reversible two-step oxidation to fumaric and hydroxyfumaric acid an important rôle as catalytic hydrogen carrier.

Dr. K. A. C. Elliott[2] ascribes my results to a simple methodic error, and doubts the possibility of generalisation. Owing to the nature and bulk of evidence, discussion is impossible within the limits of these columns. I must refer to the complete paper which I hope to publish soon. Our recent experiments confirm our previous results and show that at any rate a limited generalisation is warranted. Of the two steps of oxidation: succinic to fumaric acid and fumaric to hydroxyfumaric acid, the latter is quantitatively the more important. Malic acid is not activated. The apparent activation of this substance is due to the presence of fumarase. This might explain Elliott's results.

Giant Cells in Insects Parasitised by Hymenopterous Larvæ

IN a recent paper, A. Paillot[1] directs attention to the giant cells present in aphids parasitised by Hymenoptera, and he affirms that these cells originate from the sexual cells of the host. In support of this conclusion, Paillot states that he has once observed in a female of *Chaitophorus aceris*, parasitised by *Aphidius ribis*, Hal. a group of cells (considered by him to be germinal cells) in process of dispersion, and that these elements already showed the structure of giant cells.

Giant cells, appearing as opaque white globules of various sizes, are invariably present in weevils of *Sitona lineata*, L., containing immature larvæ of the braconid, *Dinocampus (Perilitus) rutilus*, Nees. Investigation[2,3] has shown that these cells are the hypertrophied cells of the embryonic membrane of the parasite egg. When the larva emerges from the chorion, the cells of the embryonic membrane dissociate and become free in the body cavity of the host. They then increase greatly in size, absorbing fatty matter from the body fluid. They constitute the principal food of the larva in its later stages. It was found that these cells continued their development even should the parasite larva die young, and they may then attain an abnormally large size. This point is of interest in view of Paillot's statement that he has found giant cells present in aphids without a developing parasite larva, and in such cases he considered that the parasite embryo had been completely reabsorbed.

Dissociation of the cells of the embryonic membrane, either singly or in groups, and their persistence during parasitism, has been observed in various parasitic Hymenoptera, and the literature on this subject has already been discussed[3]. Since then, a paper by Oglobin[4] has come to my notice, in which he gives a detailed description of the origin and development of the giant cells in *Dinocampus terminatus*, and his account agrees in all essentials with my observations on *D. rutilus*. Further contributions to this subject are to be found in Parker's studies of *Macrocentrus gifuensis*, Ashmead[5], and *Meteorus nigricollis*, Thomson[6]. In the Aphidiini, Spencer[7] has found that the serosa breaks up into pieces when the larva hatches. The serosal fragments become rounded off and increase in size. They are afterwards eaten by the larva. I have no doubt that these serosal fragments constitute the "giant cells" observed by Paillot.

In an earlier paper[8], Paillot comments on the giant cells found in caterpillars of *Pieris brassicæ*, and he considers that they originate from the ordinary elements of the blood of the host. He suggests that the influence inducing the hypertrophy of these cells

may be connected with the presence of the larvæ of *Apanteles* Faure[9] has found that the presence of giant cells in the blood of caterpillars of *P brassicæ* is a sure indication of parasitism by *Apanteles* larvæ. Grandori[10] has described how in *A glomeratus* the cells of the embryonic membrane dissociate when the larva hatches, and he states that these cells preserve their vitality to the end of the larval life It is therefore highly probable that, in this case also, the giant cells referred to by Paillot are derived from the embryonic membrane of the parasite.

It is not yet known in how many groups of parasitic Hymenoptera dissociation of the embryonic membrane and later hypertrophy of the cells occur, and it is probable that in many forms no such phenomena take place. Chrystal[11] observed that, in the cynipoid, *Ibalia leucospoides*, Hochenw , no dissociation of the trophamnion occurred, and in the ichneumon, *Pimpla examinator*, F , I have been unable to find either a cellular membrane or dissociated cells in the egg at the time of hatching, though at an earlier stage the embryonic membrane is distinct.

The Breeding of a Grey Mullet, *Mugil capito*, Cuv., in Lake Qarun, Egypt

THE common grey mullets of Egypt, *M cephalus* (Linn.) and *M capito*, Cuv , feed and grow in the delta lakes and are presumed to spawn near the sea coast.

Lake Qarun lies some two hundred kilometres south of the Mediterranean coast The salinity is increasing and the gradient between fresh and salt in the water is such as to resemble the delta habitats of the mullets.

In the autumn of 1928 one of us succeeded in introducing to this lake 20,000 live fry, chiefly of *M cephalus*, the larger of the two species As these fry grew up but did not give rise to any second generation, continuous stocking was resorted to from 1932 onwards, with results that are shown in tabular form below ·

Year	Date of fry transfer	Number of fry introduced	Mullet landings in kgm *M. cephalus* 1929–31, *M cephalus* and *M capito* after	Salinity 1 km. east of Qualieh Island in parts per 1000
1928	Sept -Dec	20,000	——	17 19
1929	——	——	181	17 34
1930	——	——	427	17 30
1931	——	——	52	20·00
1932	16 11 31 to 10 1 32	154,000	1,154	22 40
1933	12 11 32 to 9 1 33	136,080	2,792	21·29
1934	2 12 33 to 11 2 34	257,460	42,275	18·19
1935	2 12 34 to 4 3 35	258,600	132,060 (Jan.–March)	——

Up to 1933 the weight of mullet taken from the lake bore a rough proportion to the fry introduced, but since 1934 there has been a progression of the catch (chiefly *M. capito*) that could only have been due to natural reproduction, and is out of all proportion to the fry introduced Moreover, in a tow-net sample collected on October 24, 1934, several stages of developing eggs and larvæ were found These can only be referred to *M capito*, and represent the first definite identification of these stages of the species A description will shortly be published elsewhere

Human Remains from Kanam and Kanjera, Kenya Colony

IT was with much regret that I learned that space could not be found for my reply to Prof P G H Boswell's letter in NATURE of March 9 (p. 371) about the human remains at Kanam and Kanjera Many readers of NATURE will doubtless have wondered why no comment has appeared over my signature. I would be grateful if now you would insert this brief note, and the whole matter can then be left for full discussion on my return to England at the close of my present Expedition.

L S B LEAKEY.

East African Archæological Expedition,

Tanganyika Territory
May 28

[DR LEAKEY's reply to Prof. Boswell's letter would have occupied several columns of NATURE, and space could not possibly be found for it The suggestion was, therefore, made to Dr Leakey that he should send a short reply to the specific points stated by Prof Boswell and deal with them in detail in a communication to a scientific society EDITOR, NATURE]

Polyphyletic Origin of Metazoa from Plants

BOTANISTS show us an aspect of evolution-in-progress, so far as that *can* be shown, of which zoologists tell us nothing—because there is possibly nothing to tell The evolution of plants is often indicated in terms of the appearance of the sexual differentiation in unicellular organisms, of the appearance of multicellularity, of the total life-cycle of one plant as an alternation of two generations, asexual and sexual, the individuals being sometimes morphologically distinct and independent, and of the various fate of these phases of the total life cycle in, say, the moss, the fern and the angiosperm, when they are not distinct and independent individuals, "but the one remains permanently connected to the other like a parasite on its host plant" in Strasburger's words.

This aspect of evolution applies just as much to animals as to plants , the vertebrate, like the angiosperm, is an integration of two phases of a life-cycle, the sexual phase being greatly reduced ; and other

metazoan phyla exhibit other modes of development of the life cycle But they do not exhibit the development 'in progress', so to speak, each exhibits a particular mode established There is as great a diversity among animals as among plants as to what constitutes what may be called the individual, and there is no trace at all of the development of such diverse types of individual—in *animal* evolution

At the same time there is a conspicuous lack of plausible genetic affinities among the animal phyla Zoologists make half hearted suggestions as to phyletic affinities and with more heart indulge themselves in the construction of hypothetical ancestral forms for the different phyla But once the possibility is entertained of deriving metazoan phyla from the less specialised multicellular plants, it is easy to see why Echinoderms, especially the extinct Crinoids, are such paradoxical animals, *Hydra viridis* and *Convoluta roscoffensis* are no longer dubious cases of symbiosis but animals which retain something of the character of their plant ancestors, vertebrates may be traced back, through the tail of the larval Ascidian and the Tunicates with no tailed larva stage in their development, to perhaps a red alga, and there may be more than a jingling verbal relationship between Bryophyta and Bryozoa

Points from Foregoing Letters

PROF J W McBAIN considers the association of molecules as the characteristic factor in colloids, and raises the question how far it is effective in the case of long chain molecules He states that in concentrated solutions of simple sulphonic acid, molecular association, rather than inter-ionic attraction, is responsible for the increase in conductivity, freezing point lowering, etc

The Raman spectra of benzenes containing heavy hydrogen (C_6D_6 and C_6H_5D) are described by a group of seven investigators from University College, London, and are compared with observations by Klit and Langseth. The evidence, it is stated, permits the view that the benzene molecule has a plain regular hexagonal structure (D_{6h} symmetry)

Prof. J. Kaplan submits an afterglow spectrogram obtained by passing a current of low density through nitrogen It shows a great enhancement of the relative intensity of the Vegard-Kaplan bands which, the author maintains, agree closely with the radiations from the night sky With a rapidly interrupted discharge and low current the relative intensity of the green auroral line is also greatly increased, suggesting that it may arise in the afterglow.

A new method of calculating the charge of an electron from the electronic diffraction produced by crystals, has been devised by S v Friesen (by combining de Broglie's equation with the formula for the Rydberg constant) Preliminary measurements give a value of $4\cdot 796 \times 10^{-10}$ E S U, as compared with $4\cdot 77 \times 10^{-10}$ by the oil drop method and $4\cdot 80 \times 10^{-10}$ from X-ray diffraction measurements

A communication from the Optical Institute, Leningrad, states that experiments carried out in the exceptionally clear atmosphere of the southern slopes of Mount Elbruz (Caucasus) with the view of detecting solar infra-red radiation of wave-lengths longer than 11 μ have given negative results

Dr. J. K. Roberts discusses the adsorption of diatomic gas molecules on solid surfaces, and concludes that the resulting adsorbed films are not continuous. Certain single surface atoms remain bare and may afterwards show catalytic activity

X-ray diffraction photographs of a nickel-iron alloy distorted by cold working are submitted by Dr W G Burgers They show that compression and stretching change the shape and perhaps the size of the lattice-spacing

The addition of cadmium, indium, tin and antimony to silver, changes its lattice structure and depresses the freezing point by an amount proportional to the valency of the added element, according to W Hume-Rothery

The dipole moments of ethyl and phenyl isocyanates have been determined by Prof J R Partington and E G Cowley From the values obtained, they infer that the $-N=C=O$ group in these compounds is linear, as is also indicated by the Raman spectra of the light they scatter

I Norvick mentions a reaction between alkyl-organic compounds of bismuth and of magnesium in which, as in the case recently described by Mrs Leigh-Smith and Dr Richardson, bismuth atoms were apparently able to wander from one organic radicle to another

Starting with sitosterol, a constituent of soya beans, R. V Oppenauer has synthesised one of the male sex hormones (dehydroandrosterone), thus elucidating its structure, which was hitherto incompletely known

The horse and cow store carotenes in their fatty tissues, while the hen stores the closely related xanthophylls, all of which are derived from vegetable sources Messrs L Zechmeister, P Tuzson and E Ernst find that, after feeding on green food, the blood serum of the horse shows an increase of carotenes and no xanthophylls Hence the selection appears to take place in the digestive organs

According to K Linderstrøm-Lang and F Duspiva, the clothes moth, *Tineola bisselliella*, digests wool keratin by means of an enzyme active in alkaline medium (pH 9 3), after the keratin has been chemically reduced by an agent as yet unknown

Giant cells found in weevils of *Sitona lineata* and other insects parasitised by hymenopterous larvæ are derived, Miss Dorothy J. Jackson states, from the embryonic membrane of the larvæ, which become dissociated when the larvæ emerge from the chorion, they do not arise from the host's cells, as suggested by Paillot in the case of *Chaitophorus aceris* and in caterpillars of *Pieris brassicæ*.

ERRATUM. It was stated in the summary of a letter in the issue of June 8, that an external magnetic field *increases* the resistance of nickel-iron wires at audio-frequencies Actually, as the letter indicated, the application of an external field *decreases* the resistance.

Research Items

Romano-British Potters' Stamps. Students of Romano British antiquities will welcome a further list of potters' stamps on *terra sigillata* from Gloucester, which has been published by Mr Charles Green, curator of the Public Museum (Occasional Papers No. 2, Public Museum, Gloucester, pp 12, 6*d*) The examples included in this second list are part of the results of extensive excavations which were carried out early in 1934 in King's Square, Gloucester The trenches pierced the north-east angle of the wall of Glevum and for some distance ran parallel to the east wall More than forty of a large number of potters' stamps proved to be legible, and form the basis of this catalogue, but a few recently discovered stamps from other parts of the city are included Fifteen of the stamps may antedate the foundation of the *colonia* of Glevum, the remainder are of the second century A D The majority of the stamps belong to various potters of Lezoux, a number come from La Gaufresenque, and two from Rheinzabern A detailed study of the Romano-British pottery which has been found in Gloucester is now in course of preparation

Natives of Angola Although the Portuguese have been established in Angola for more than four centuries, it is only recently that this vast territory of 1,200,000 square kilometres has been penetrated completely and subdued Its pacification is now so complete that M. Christian de Caters has traversed it in all directions, from frontier to frontier, without arms (*La Nature*, May 15) The natives are estimated to number between four and five millions, nearly all of Bantu race, though there are a few scattered tribes of Bushmen, leading a miserable existence, in the centre The Bantu, however, are divided into an extraordinarily large number of branches On the coast the natives have entirely lost their indigenous culture. In the north-west the Fiot or Congo, who extend from the Cabinda enclave to the neighbourhood of Loanda, have lost their culture near the railway, but in the remoter parts, although they preserve the record of their contact with civilisation in their houses, which are of European form, in which the walls are decorated with drawings of locomotives, steamboats and other like objects, they have abandoned European dress Farther east is one of the most interesting of the groups in Angola, the Lundas. Inhabiting a country which is sparsely wooded or savannah, they live by hunting with bow and lances of a peculiar and interesting form A characteristic weapon is a club in the form of a human head Some of these are negroid, others of a refined type recalling Egyptian or primitive Greek characters. Their fondness for dancing and fear of fetish are marked. Their musical instrument is the marimba or xylophone. Fear of fetish places them at the mercy of sorcerers, who are not slow to profit thereby. They are particularly skilled in the use of poisons. Generally the Lunda wear no clothes The women dress their hair with a mixture of oil and red ochre. Sometimes they wear a species of cap in brick-red and the whole of the body may be covered with a red powder.

Body Fluids of Aquatic Animals. In his presidential address before the Linnean Society of New South Wales, at its annual general meeting on March 27, Prof. W J Dakin gave an account of the relation between the osmotic pressure and the salt contents of the blood and body fluids of aquatic animals to the constitution of the external medium After touching upon the early history of the subject he dealt with his own early work, and showed how at first it seemed as if all the aquatic invertebrates were to be regarded as highly dependent upon the constitution of the water bathing their bodies, whereas the fishes and all the animals above them (reptiles, amphibia, birds and mammals) had evolved an independence which was most striking in the aquatic groups of the fishes The fact that the bounding membranes of all these animals can be shown to be permeable to water and probably to salts makes the search for the controlling mechanism one of the fundamental problems in biology Prof Dakin discussed the possible origin of the independence so characteristic of vertebrate blood and disagreed with the theories of Macallum that the salinity of vertebrate blood represented that of a primeval ocean in which the provertebrates had evolved He showed that it was possible for an aquatic invertebrate to sustain a similar independence in fresh water, and that it was quite likely that the early aquatic vertebrates had evolved their independence in fresh water. On the other hand, the salt contents of living cells as well as of body fluids might well be a relic of the origin of life in water

Breeding of a Japanese Fresh-water Bivalve. K. Okada (*Sci Rep Tôhoku Imp Univ*, 9, No 4, 1935) has studied the nutrition of the embryos of *Musculium heterodon*, a Japanese fresh-water mollusc allied to the British fresh-water bivalve, *Sphærium corneum* When the fertilised eggs come into the interspaces between the interlamellar junctions of the inner gill, the walls of adjacent junctions are eroded and thus a cavity is formed the wall of which thickens, apparently by the addition of blood corpuscles, and thus the marsupial sac is formed Its wall is single-layered and envelops eggs which are in cleavage Three or four such sacs fuse and form a larger sac, the wall of which becomes two layered and contains embryos beyond the gastrula stage This sac becomes still larger and displaced more dorsally and the embryos remain in it until they attain the form of the adult and are about 2 mm long The outer layer of the sac is the original single wall, the inner layer originates from blood corpuscles which have migrated into the sac from the hæmocœl, and the young mollusc is nourished at the expense of these blood cells of the parent

Insects Collected by the Kalahari Expedition. Certain of the scientific results of the Vernay Lang Kalahari Expedition, 1930, are reported upon in the *Annals of the Transvaal Museum*, 16, Part 4, Feb. 1935 The collecting of specimens took place between the months March and September and, since this period was at the close of the rainy season, the material obtained was not so abundant as might have been expected had the work taken place earlier The Sphegidæ and Psammocharidæ are dealt with by Dr. G. Arnold, who describes five new species and one new variety belonging to the first mentioned

family and two new species of Psammocharidæ. In Dr A J Hesse's account of the Mutillid wasps, he records 11 genera and 31 species of the family, of which 8 species were previously undescribed, together with several minor forms. This same authority is also responsible for working out the beetles of the family Tenebrionidæ—a group represented by more than 2,300 specimens This extensive collection, although exceedingly rich in numbers, is comparatively poor in genera and species which were obtained by the expedition on their journey through the extensive region of Nganiland and northern Bechuanaland It is, however, of special interest, since no material has been hitherto available from the Kalahari Desert Out of 114 species obtained, 16 are described for the first time The other reports in the present contribution deal with the Heteroptera, the blood-sucking Diptera and the Trypetidæ

Bird Malaria. K S Shah (*Amer J. Hyg.*, **19**, 392–403, 1934), in view of the deficient information and divergent views on the incidence and development of gametocytes (crescents) in human malignant malaria (*Plasmodium falciparum*), has investigated birds infected with the malaria parasite *Plasmodium cathemerium*, which resembles in morphology and life cycle the species *falciparum* He states that when the canary is infected with *P cathemerium*, gametocytes appeared in the peripheral circulation early in the infection and in the majority of cases simultaneously with the asexual forms The number of gametocytes increased with the increase in asexual forms and the incidence was highest at the peak of infection, the number of gametocytes diminished with the fall of the infection In a later paper in the same journal (pp 502–507, 1934) Shah, Rozeboom and del Rosario record that gametocytes were present in sufficient numbers in the peripheral blood, during the early period of patency, to infect mosquitoes (*Culex pipiens*), that the chances of mosquitoes becoming infected were greater when they were allowed to feed at night than during the day, and that when canaries were experimentally infected with sporozoites the gametocytes appeared in the peripheral blood early in the infection and in most cases simultaneously with the asexual forms.

Eelgrass in the Atlantic. Many interesting problems were presented to biologists and to all interested in problems connected with the Atlantic coast-line, by the rapid diminution, reported from both the American and European sides of the Atlantic Ocean during 1931 and 1932, of the eelgrass (*Zostera marina*), which grows on mud shores, at levels where it is usually submerged by the sea. The plant is widespread and ordinarily grows in dense mats on the mud flats of bays and estuaries, and as its disappearance was often extremely rapid so that 99 per cent of the original vegetation disappeared within one season, the phenomenon was exceedingly striking and aroused widespread attention. A very interesting summary by Clarence Cottam, of the data accumulated as a result, is issued by the United States Department of Agriculture, as *Wildlife Research and Management Leaflet*, BS-3, February 1935. Many causes have been suggested for the widespread disappearance of the plant, which has not been associated with any similar disappearance of the species of *Zostera* fringing the Pacific coast-lines. Several parasitic causes have been suggested (see NATURE, **134**, 416; 1934), and these are briefly reviewed and the complexity of the problem stressed. Eelgrass has many direct commercial uses in different countries, as an insulator, as a packing material, in upholstering, etc, but its main biological importance is as a food or as a sheltering habitat for the natural food of many waterfowl The effect of its general disappearance is closely examined It normally forms more than 80 per cent of the food of the sea brant, and there is evidence that the numbers of this species on the coast of North Carolina were very seriously reduced (down to 2 per cent) in the winter of 1934–35 as compared with 1929–30 Fortunately, in other areas the reduction has not been so severe The writer points out that there is evidence that previous periods of scarcity of eelgrass have been experienced on the Atlantic seaboard, and he finds some evidence for a recovery of the plant in certain areas, both on the American and European coasts

Water Mould Fungi. A paper by Miss Evelyn J Forbes (*Trans Brit. Mycol Soc*, **19**, Part 3, 221–239, February 1935) reports a study of water fungi, using methods recommended by American workers. Samples of water are 'baited' with sterilised hemp seed, which induces the fungi to grow Cultures are purified by teasing out hyphæ under a binocular microscope and removing pieces bearing spores to plates of malt agar or corn meal agar Samples of natural waters from the Bristol district yielded twenty-two species of aquatic fungi, fourteen of which are new to Britain. The new records include ten species of the genus *Achyla*, two of *Rhipidium*, one of *Calyptralegnia*, and one of *Brevilegnia*. The species are described in detail, and three plates further enrich their characters

Microseisms at Kew. In a recent memoir (*Meteorological Office Geoph Mem*, No 66, 1935), Mr. A W. Lee continues his interesting studies on microseismic disturbances recorded by the Galitzin seismograph at Kew The north–south, east–west and vertical components of the microseisms have been tabulated for four hours daily throughout the year 1932. The mean amplitudes and periods for the whole year of the three components are approximately equal (0·9μ and 5 6 sec.) The amplitudes of the two horizontal components are nearly equal for all periods, but the ratio of the horizontal to the vertical amplitudes decreases from about 1 2 for microseisms of period 4½ sec to 0 85 for those of period 9 sec., a variation that is consistent with the hypothesis that the microseisms may be regarded as Rayleigh waves through granite covered by a superficial layer. The vertical component is more trustworthy than either of the horizontal components for the measurement of microseisms, as there are no uncertainties due to changes in the direction in which the waves travel, and it is less affected by the local geological structure. Since the beginning of the present year, it has therefore been used for the tabulation of microseisms at Kew Observatory

Snow Crystals Observed in Japan. In the *Journal of the Faculty of Science* of Hokkaido Imperial University, Sapporo (Physics, Dec. 1934), there are two interesting papers on snow crystals. The first paper, by U. Nakaya and K. Hasikura, describes 250 photographs of snow and frost crystals they obtained at a sheltered cottage half way up Mount Tokati at an

altitude of about 3,400 ft The spot was protected from strong winds and very favourable to the formation of large and perfect crystals, the temperature being nearly constant at $-10°$ C. At this temperature, it was possible to separate some of the crystals into their components and to cut others so as to get good photomicrographs Some novel shapes were obtained At Sapporo it was relatively warm and humid, and crystals with water droplets were frequently observed All the types obtained are classified and ninety-eight large photographs are given showing minute details The second paper, by V Nakaya and T. Terada, discusses the electrical nature of snow particles The authors use an electric deflexion method of measuring the charge The frequency of occurrence of negatively charged snow was the more common Sometimes 90 per cent of the crystals were negatively charged When the crystals had attached water droplets the positive particles tended to be more frequently observed They were unable to verify when a large snowflake split by mutual friction into large and small portions that the large parts were positively electrified and the small ones negatively electrified They intend continuing similar measurements on various types of snow crystals next winter

Electrical Analysis of Human Language. Vol 18, Nos 3 and 4 of the publications of the Psychological Institute of the University of Milan reports an interesting investigation into the function of human language by means of an electrical analysis, by A Gemelli and C Pastori By electrical apparatus, the oscillographic curves of words and sentences can be recorded, and the writers claim that the laws governing sensory perception and movement are equally applicable to language Language is a sequence of sound organisations each of which is, by itself, a more or less constant whole. Each word is shown by oscillographic curves to be a whole consisting of different sounds These sound elements can be investigated separately, but they derive their meaning from the whole of which they are parts, and in turn influence the whole The same holds for the sentence as a whole It is also a unit and at the same time a system of words and movements. Various factors influence these movements, and of these melody seems to be particularly important as a means of unifying and totalising. To these unified and organised movements that build up language there are corresponding organisations on the perceptual side · in this way meaning enters and makes understanding of language possible.

Recombination of Hydrogen and Deuterium Atoms. Many investigations have been made of the mechanism of recombination of hydrogen atoms with the object of specifying the efficiencies of the third bodies necessary in collisions producing molecules. I. Amdur (*J. Amer. Chem. Soc*, **57**, 856; 1935) has made experiments in which hydrogen or deuterium is dissociated in a Wood discharge tube, and the mixture of atoms and molecules is pumped along a recombination tube with the walls covered with phosphoric acid. Atom concentrations were measured by means of a small platinum catalyst calorimeter which could be lowered to various positions in the tube. In agreement with results of Smallwood, the recombination of atomic hydrogen was found to proceed homogeneously as the result of triple collisions involving atoms rather than molecules as third bodies, so that the rate equation becomes $-d[H]/dt = k[H]^3$ An analogous equation holds for deuterium The values of k for H and D are $2\ 05 \times 10^{16}$ and $1\ 51 \times 10^{16}$, the ratio being $1\ 36 \pm 0\ 06$ If the diameters and interatomic forces are assumed to be the same for hydrogen and deuterium atoms, the theoretical ratio is 1·41 (that is, $\sqrt{2/1}$). The approximate agreement indicates that the diameters and forces are equal Viscosity measurements have shown a similar equality of *molecular* diameters and forces for H_2 and D_2

Theory of Groups. Four recent numbers (194, 195, 198, 205) of the series "Actualités Scientifiques et Industrielles" (Paris: Hermann et Cie, 1935) deal with various aspects of the theory of groups H Cartan's 'Sur les groupes de transformations analytiques" and E Cartan's "La méthode du repère mobile, la théorie des groupes continus et les espaces généralisés" deal with Lie's theory, the first from the analytical aspect, the second from the geometrical, using the familiar notion of moving axes These two pamphlets are written so as to make them intelligible to non-specialists The other two are on the algebraical side, and make heavier demands on the reader R Baer's "Automorphismen von Erweiterungsgruppen" is closely connected with the work of A Speiser and I Schur R. Brauer's "Über die Darstellungen von Gruppen in Galoisschen Feldern" is a continuation of the work of G. Frobenius and L. E Dickson

Airway and Aerodrome Lighting. The technique of aviation lighting has now reached an interesting stage Further progress depends on attaining a clearer understanding of what the lights should do and the best way of arranging them At a joint meeting of the Illuminating Engineering Society and the Royal Aeronautical Society held on March 12, Mr H N Green described some recent developments. A light is said to be 'visible' when the illumination it produces on the eye exceeds a certain minimum known as the threshold illumination Experiments prove that a light of 0 5 candle power at a distance of one mile can be located without undue difficulty or delay by observers wearing goggles and subjected to local lighting equivalent to that in an aeroplane cockpit It is known that white light can be recognised more easily when looking slightly away from it; the threshold illumination for 'parafoveal' vision being only one fifth of that necessary when it is viewed directly. A light seen obliquely can be identified when its conspicuity is of the order of 0 1 mile candle The practical value is taken as 0 5 mile candle The most important lights are the beacon lights which are placed near the airway to indicate the route It has been noticed that powerful lights at long range are easier to see in bad weather than lights of less intensity at shorter ranges. The time taken to locate a flashing beacon is partially dependent on the period elapsing between flashes Experience has led to the use of periods not exceeding five seconds The beacons required to locate the aerodrome are built up of neon tubes giving 4,000 candles of red light. To identify the aerodrome they flash a Morse signal. This is necessary as the exterior neon lighting of cinemas often exceeds that of a neon beacon. The boundary lights are not yet standardised internationally, but the aerodrome obstruction lights are always fixed and of a red colour

Prehistory of Northern Africa

AN important study of the archæology and racial history of the western area of North Africa, published by the Institut de Paléontologie humaine,* arises out of the investigation by M C Arambourg in the years 1927–30 of a series of caves in the hills which fringe the Gulf of Bougie on the coast of Algeria Several of these caves were already known to archæologists and palæontologists, and finds in them have been described from time to time, but no systematic investigation had been undertaken previously.

The cave of Afalou-bou-Rhummel is a large shelter of ten metres in depth with an opening about twenty metres wide Its deposits were first examined by trenching along the axis of the cave to a depth of 0 15 m over a length of 17 metres The ossuary was found at a depth of between 3 25 m and 4 m at about three metres from the south wall Eight complete skeletons and about fifty skulls were recovered Another complete skeleton, with the cranium of a child, was found later at a lower level

The deposits of the cave fall into two sections of which the upper only, reaching to a depth of 7 50 m, contained evidence of human occupation The lower, archæologically and palæontologically sterile, reaches bed rock through a depth of 8 metres

The upper stratum of the archæological level to a depth of 4·40 m contains a uniform industry, of which the chief characteristic is a microlith *à dos retaillé* of the 'La Mouillah' type The food debris consist almost entirely of marine shells Below is a deposit 1 metre in thickness in which there is no variation in the industry, but the deposits are of a reddish yellow in colour and the debris of food include some bones of the moufflon in addition to the marine shells Below this is a sterile layer of 50 cm thickness which overlies the third archæological layer of reddish thickly compacted deposits 1 8 m thick, in which the animal remains constitute a veritable bone bed Not only was the food-supply of the inhabitants of this period more varied than that of their successors, but also their stone industry, though essentially identical, was more abundant. Below this the sterile layers begin

The human remains were found in a state of confusion and many of the bones were calcined The industry of the archæological levels consists almost exclusively of flint and polished bone-blades, flakes and scrapers It is virtually identical throughout except that in the upper and later levels there is an increase in the percentage of microliths Among the molluscs which served as food, *Patella*, *Trochus* and *Helix* are very common, and among the mammalia the dorcas gazelle, moufflon and *Bos primigenius* are frequent.

In the rock-shelter of Tamar-hat, which is now about six metres broad by eight metres deep, but once was much larger, trenching revealed an uninterrupted succession of archæological deposits of more than five metres depth Here, also, through a succession of five distinguishable levels, there was what is essentially an identity of industry—again with a predominance in the later stages of the small blades. The vertebrates and mollusca appear in the same relation as at Afalou, but *Hippotragus* appears here for the first time in North Africa.

Taking into account certain positive and negative characters, M Arambourg arrives at the conclusion that the industry from the two cave sites is typically Ibero-Maurusian and comparable with that industry as identified on other sites in North Africa in a distribution extending from Morocco to Tunis As a result of an analysis of the upper palæolithic stone age of North Africa, he also concludes that the Ibero Maurusian industry, lying between Mousterian and Maurotanian neolithic, is to be considered as a facies of the Upper Palæolithic, parallel to the Capsian facies, of which it takes the place on the littoral of Constantine, in Oran, Algeria and Morocco This view is corroborated by the identification of Capsian man and Ibero Maurusian man, now made possible by the discovery of skeletal remains in the cave of Afalou

M Arambourg goes on to wider inference that a similar interpretation is to be placed upon the succession of specialised industries of the Upper Palæolithic elsewhere, as, for example, in Kenya and South Africa These, as the Capsian and the Ibero-Maurusian, are to be regarded as specialised and locally evolved Aurignacian.

The skeletal material from Afalou is examined by MM Boule, Verneau and Vallois It consists of fifty skulls and nine complete or approximately complete skeletons, of which ten are definitely not adult All the skulls are robust in type, but, with the aid in certain cases of the indications afforded by the pelvis, 26 men and 14 women can be distinguished among the adults Thirty-two of the adult skulls are now sufficiently complete for measurement in detail They present a well-marked type. The cranium is of medium form, the face broad and low, with well-marked glabella and superciliary ridges The cheek bones and zygomatic arches are massive. There is no prognathism The maximum length varies from 193 mm to 206 mm and breadth from 133 mm. to 159 mm. It will be noted that in breadth they approach that of brachycephalic or mesocephalic peoples of Europe The mean of the cranial capacity for men is 1,622 c c, for women 1,456 c c Essentially they are dolichocephalic, or mesocephalic, and the sexual difference is insignificant. Evulsion of the upper incisors was practised. Taken as a whole, the remains represent a homogeneous group which, as indicated by the long bones, was of more than average stature. The bones of the skeletons have been subjected to a careful examination, of which the results are described in detail

As the result of a detailed comparison with the remains of fossil men of palæolithic age found in North Africa and also with 'fossil' man elsewhere, and more especially with the skeletal remains from Mechta el-Arbi, here studied and described as a complete whole for the first time, the authors conclude that Afalou man approaches most nearly to the Cro-Magnon man and belongs to a North African group, here styled "the Mechta type". This type persists through neolithic, bronze and iron ages and reappears in the population of the Canaries. Though it is possibly to be discerned in the Carthaginian and Roman periods, it appears to have contributed nothing to the modern Berber population.

* Les grottes paléolithiques des Beni Segoual (Algérie) Par C. Arambourg, M. Boule, H. Vallois, R. Verneau (Archives de l'Institut de Paléontologie humaine, Mémoire 13.) Pp 242+22 plates. (Paris Masson et Cie, 1934) 180 francs.

Solar Telescope at Oxford

THE new solar telescope of the University Observatory, Oxford, which was formally declared open by the Vice-Chancellor on June 11, is in its essence a vertical Cassegrain telescope of 12½ inches aperture and 73 feet focal length It gives a solar image some eight inches in diameter, and unlike the original tower telescopes (the 60 ft and the 150-ft at Mount Wilson) the present instrument is wholly free from chromatic aberration Further, since the image is formed on the optical axis, the telescope is free from the extra axial aberrations characteristic of horizontal solar reflecting telescopes. Light is fed into the vertical Cassegrain telescope by a 16-in cœlostat, driven by a synchronous motor, and a secondary mirror of the same aperture Both cœlostat and secondary mirror are provided with electrical slow motions which are controlled by a portable keyboard near the focal plane of the instrument, the same keyboard also carries controls for focusing the Cassegrain mirror

The telescope is unique in that it is the only large solar telescope in which all the optical parts are made of fused silica Since fused silica has a coefficient of expansion 1/20 that of ordinary glass, and 1/7 that of pyrex, it follows that the differential expansion produced by solar radiation, which tends to make the plane mirrors concave and so to produce an astigmatic image, will be almost wholly avoided in this instrument The telescope, mounted in the east tower of the observatory on the same pier and under the same dome which housed the De la Rue reflector, was constructed by Sir Howard Grubb, Parsons and Co, of Newcastle, the blanks for the fused silica discs having been supplied by the Thermal Syndicate, Ltd.

On the optical axis of the telescope lies the slit of a large Littrow spectrograph The spectrograph has two 60° and one 30° prisms of six inches square aperture (height 6 inches, length of face 9 7 inches), and a collimating-camera lens of six inches aperture and some 30 feet focal length It gives a dispersion at λ4200 of 2 6 mm. per A, and a theoretical resolving power of more than 300,000. The optical parts, supplied by Adam Hilger, Ltd, and a large minimum deviation mount, supplied by C. F. Casella and Co, Ltd, are mounted at one end of a 40-ft. brick tunnel constructed in the basement of the observatory. The spectrograph, which still lacks the essential temperature control for the prisms, the slit end and plate holder mechanism, and a guiding disc, will be completed as funds permit.

In declaring this equipment open, the Vice-Chancellor referred to the chequered history of attempts to establish a permanent observatory in Oxford No less than three unsuccessful attempts have been made, namely Bishop Fell's failure to persuade Wren to incorporate an observatory in Tom Tower, the establishment of a temporary observatory for Halley in 1704 in New College Lane, and finally the construction of an observatory by the Radcliffe Trustees in 1773, now regrettably, from the point of view of Oxford at least, departing for South Africa The University Observatory was built by the University some sixty years ago, and the fact that the University has, during a period of exceptional financial stringency, set aside some £3,700 for the purchase of the present equipment may be regarded as evidence both that it desires the present observatory to be a permanent institution, and that it desires to see the study of observational astronomy actively prosecuted at Oxford The Vice-Chancellor concluded his remarks by expressing the warm hope that some donor, interested in the study of astronomy, would find it possible to provide the relatively small sum needed to complete this equipment.

After the Vice-Chancellor's declaration, and following a period when the instruments were inspected by the assembled company of astronomers, Oxford men of science and other members of the University, the proceedings were concluded by an address by Sir Arthur Eddington on "The Physics of the Sun". Sir Arthur pointed out that the sun may be regarded as composed of three parts, an airy appendage where the atoms are supported by radiation pressure, a middle region where the absorption lines are formed and which is therefore readily accessible for observation with the equipment which had just been inspected, and finally the observationally inaccessible deep-lying interior While there is a temptation to separate what is observable from what can only be inferred, the creation of such artificial divisions is likely to lead to 'frontier incidents' The sun is a unit and must be treated as such. Sir Arthur then went on to point out how, in spite of its inaccessibility, it is possible to infer much about the physical conditions in the deep interior, and how such information has been confirmed in a striking way by developments in nuclear physics. In moving a vote of thanks to the lecturer, Prof E A. Milne, in a peculiarly happy vein, referred to the many distinguished astronomers and solar physicists who gathered to witness the ceremony and to hear Sir Arthur's masterly address.

H. H. P.

Interpretation of Spectra

PROF. HENRY NORRIS RUSSELL delivered the George Darwin Lecture to the Royal Astronomical Society at the meeting of the Society on June 14, taking as his subject "The Analysis of Spectra and its Application to Astronomy" Prof. Russell explained that he did not refer to the analysis of spectra in the sense of the analysis of the elements present or absent in a mixture, but to the analysis of the spectrum of each single element. The history of this analysis goes back to 1883, when it was discovered that the various doublets in the spectrum of sodium possessed the same separation when expressed in wave numbers: Prof Russell followed the development of this subject down to its rationalisation by Bohr and the introduction of the notion of states of energy which the atom may possess, the frequencies of the spectral lines being given by the familiar quantum relation $h\nu = E_1 - E_2$

Comparatively recently, Hund has given a theory of the way in which the energy states of the atom are built up from the energies of the various electrons in the atom, and there is now a corpus of complicated but definite rules which govern the way in which levels are built up and the restrictions on possible electron jumps, jumps between 'odd' and 'odd' terms, for example, being forbidden We can now fully understand the structure of even a complicated spectrum such as that of iron

Turning to the practice of the analysis of spectra, Prof Russell said that, before one could analyse a spectrum, one needed a list of lines with well-determined wave-lengths, the intensities of the lines, their temperature class (along the lines developed by King at Mount Wilson) and the Zeeman patterns All the easy spectra have now been unravelled, but a few complex spectra remain to be analysed Prof Russell showed a slide exhibiting the present state of completeness of the analysis of the spectra of all the elements. Amongst those which are least analysed are the spectra of gadolinium, terbium, dysprosium, holmium, erbium, thorium, and uranium, while among the lighter elements the spectra of phosphorus, sulphur and chromium are not well analysed

The astrophysical applications of the newer spectrum analysis were numerous Saha's relation between the numbers of neutral and ionised atoms present in equilibrium at a given temperature and pressure had given the key to the general interpretation of the stellar spectral sequence Identifications of lines are made much more reliable when reference is made to the intensity to be expected from the line's place in a multiplet and to the excitation potential of the atom in the state which absorbs the line Identifications in the far infra red spectra are particularly assisted by spectrum analysis, as very accurate wave-lengths are not to be obtained from laboratory measurement · a more accurate separation can sometimes be obtained from a corresponding separation in, say, the green, where good wave-lengths are obtainable Again, the presence or absence of lines in the solar spectrum receives an explanation based on spectrum analysis The non-metals do not show strongly, because the lines arising from atomic states with low excitation potentials lie in inaccessible regions of the spectrum The great majority of apparent variations in abundance between the earth's crust and the solar disc is explained by the excitation potentials of the lines that are available Only phosphorus, bismuth and radium are truly absent in the sun Passing on to quantitative analysis, the theory of R H Fowler and Milne explained the major features of the spectral sequence, the apparent differences between one spectrum and another being due to differences in surface temperature and surface gravity

Prof Russell went on to say that while we recognise that a strong absorption line indicates many absorbing atoms and a weak line few, the detailed physical analysis is difficult Dr W S Adams and Prof Russell had calibrated Rowland's scale of intensities--an arbitrary scale—by comparing Rowland's estimates of relative intensities within a large number of multiplets with theoretical intensities, and had applied this to the analysis of a number of stellar spectra. They discovered a departure from thermodynamical equilibrium , but recent work by Struve has thrown doubt on this method of calibration and the departure from thermodynamical equilibrium must now be regarded with caution Prof Russell concluded the lecture by referring briefly to bright line spectra and to the spectra of the planets

Association of Teachers in Technical Institutions

At the twenty sixth Annual Conference of the Association of Teachers in Technical Institutions, which was held at Bournemouth during Whitsuntide, Mr D. W Lloyd (Old Trafford Technical Institute, Stretford) was installed as president for 1935–36 by the retiring president, Mr H J Cull (Central Technical College, Birmingham)

In his presidential address, Mr Lloyd said that during the past twenty five years two dominant motives have been apparent—the desire to preserve and extend liberty of thought and speech and the desire to mitigate human toil The first is in the realm of social and political life ; the second in the sphere of science and industry Both, however, have produced effects which are world-wide and touch the sphere of education at every point To the technical teacher, said Mr Lloyd, the tremendous changes in our industrial system due to technological development must have special significance "Magic has entered our research laboratories, scientific advancement and the mechanisation of industry have tended to shorten hours of labour and increased the possibilities for leisure, yet, in our present stage of our development, we are faced with the chaos and misery of unemployment." Rationalisation, he continued, is one of the results of the increasing application of science to industry ; but it has produced (by the replacement of as many employees as possible by the minimum number of machines) the paradox of a world of increasing production in which vast numbers are unable to secure the necessities of life. The machine, however, should not be arrested, since mechanical perfection increases human possibilities, and since the machine can "do the job better than its creator".

Long-range planning in industry and education, however, becomes essential "The isolation of countries has disappeared . geographical barriers are non-existent except to those who think in ancient terms, international wireless communication has no limits unless hampered by those who fear the free movement of thought . . new industrial contacts are possible , under control they can expand and make friendships. Education in its widest aspects can become an international force, and thus help to replace the narrow spirit of nationalism by the wider appeal of internationalism."

Mr Lloyd specially stressed the need for liberty of thought. The unrest of the present world, he said, has produced intolerance and the stifling of criticism . in certain cases it has led to the establishment of dictatorial power which must have a reactionary effect on educational progress. Civilisation cannot advance without criticism, and the subjection of the individual will by inhibitions from the outside leads to stagnation and putrefaction. Propositions which may seem obscene, heretical and revolutionary will

get their deserts if openly discussed; but if they are suppressed they will permeate society through insidious channels and do irreparable injury. Freedom to think, freedom to voice one's thoughts within reason, are essential to human progress.

The Conference approved the recommendations of the "Report on Policy in Technical Education" recently published by the Associations of Technical Institutions, Teachers in Technical Institutions, and Principals of Technical Institutions and the National Society of Art Masters. Among other resolutions passed was included one urging the establishment of a system of compulsory part-time day education for all young persons from the age of ceasing compulsory attendance at schools giving full-time education to the date at which the pupil attains the age of eighteen years. The Association reiterated its opinion that the raising of the school leaving age is more than ever desirable. In view of Mr. Lloyd's address, special interest centred about a resolution urging that the conditions of apprenticeship should be restated for the several industries, and that special consideration should be given to the claims of young people who have satisfactorily completed a full-time course in approved technical institutions in respect of the age at which they may be recruited, and the period of time required of them for completion of apprenticeship.

University and Educational Intelligence

CAMBRIDGE.—Dr. Leslie Harris, director of the Nutritional Laboratory, has been awarded the degree of Sc.D. Dr. Harris is known for his work on vitamins and proteins, and for the latter was awarded the Meldola Medal by the Institute of Chemistry in 1924.

EDINBURGH.—Dr. Otto Samson has been appointed Tweedie fellow for 1935–36 and 1936–37. This fellowship is awarded to enable the holder to carry out exploration and research in the less-known regions of Asia and northern Africa. Dr. Otto Samson was born in Hamburg in 1900, and studied political science and then Oriental languages at the University there. In 1928 he entered the famous Ethnographical Museum (Museum für Völkerkunde) in Hamburg, and in 1930 became head of the East Asiatic Section, a post he held until the Nazi revolution in 1933. In 1931–32 he travelled in China to collect ethnographic specimens for the Museum. In the course of his travels he made an intimate study of the daily life of peasants and craftsmen and of the technical processes employed by them. An examination of the data then collected suggested connexions with India reflected in craft and agricultural processes and their products. It is the extent and direction of the influence of China upon India and vice versa that Dr. Samson now proposes to study.

LONDON.—The Governing Body of the Imperial College of Science and Technology has elected to an Imperial College fellowship Prof. Alfred Fowler, late Yarrow professor of the Royal Society, and emeritus professor of astrophysics in the College.

OXFORD.—The new solar tower telescope was opened at the University Observatory by the Vice-Chancellor on June 11 (see p. 1047).

Sir Peter Chalmers Mitchell (scholar 1884–88), and Prof. N. V. Sidgwick (scholar 1892–96) have been elected honorary students (that is, fellows) of Christ Church.

The course of lectures on the work of early Oxford men of science finished for the session with Dr. R. T. Gunther's lecture at Exeter College. Special reference was made to the work of Borlase on the antiquities and mineralogy, and of Walter Moyle on the ornithology of Cornwall. Of outstanding importance was the advance in the science of geology due to Sir Charles Lyell, while the history of mathematics and astronomy owes much to Prof. Steven Rigaud, whose library was dispersed by the Radcliffe Trustees less than two months ago. Dr. Gunther concluded with a tribute to the biologists, Prof. H. N. Moseley of *Challenger* fame, Sir Baldwin Spencer of Australia and Sir Ray Lankester—all of Exeter College.

THE University of Pittsburgh has conferred the honorary degree of doctor of science on Dr. William A. Hamor, assistant director of Mellon Institute of Industrial Research, Pittsburgh.

MR. H. G. ROBINSON has been appointed principal of the Midland Agricultural College, Loughborough, in succession to the late Dr. T. Milburn. Mr. Robinson, who is a graduate of the University of Durham, is a son of Mr. G. Goland Robinson, a well-known south Westmorland farmer. Since 1929, he has been farm director in the Midland Agricultural College.

Science News a Century Ago

Portrait of Count Rumford

In June 1835, the Managers of the Royal Institution received and accepted from Sarah, Countess Rumford, the portrait of her father, Count Rumford, the founder of the Institution, which hangs now in the Managers' room. The painting, which presents the Count in uniform, is of head and shoulders in profile. It is by an unknown artist, but is believed to be a good likeness. Count Rumford, who died in Paris in 1814, had kept the lease of his house at Brompton, although he had not lived in it for many years. His daughter occupied it again in 1815, and lived there at intervals until 1835. In that year she returned to America, presenting the portrait to the Royal Institution as a parting gift.

Roberts's Miners' Safety Lamp

According to *The Times*, on June 23, 1835, a lecture was given to the Eastern Literary and Scientific Institution by Mr. Taylor in the room usually used by the Institution in Hackney Road. "The subject of the lecture was the safety lamp, and the object of the lecture was to show, by actual experiment, that the lamp hitherto used in coal-mines, and invented by Sir H. Davy, is dangerous and insecure, and that a lamp invented by Mr. Roberts is perfectly safe and free from the defects which render the lamp of Sir H. Davy not to be depended on by the miners. Mr. Roberts, who has already received several medals from the Society for the Encouragement of Arts, Manufactures and Commerce, was in attendance and produced the lamp invented by Sir H. Davy and his own lamp, and assisted Mr. Taylor in the lecture and in the experiments."

Roberts's lamp was described as being "surrounded by a double tube of wire gauze, and also by a glass chimney, and is so constructed that a current of carbonic acid air or nitrogen passes continually between the external atmosphere and the flame of the lamp To comprehend the nature of this invention fully, it is necessary to see the lamp, and compare it with the lamp hitherto used, over which it has certainly a manifest advantage It is very simple in its construction, and as a committee of the House of Commons are now examining matters of this nature, it will no doubt meet with the encouragement it deserves"

London's Water Supply

Commenting on a proposal to supply London with water pumped from wells by steam engines, the *Athenæum* of June 27, 1835, after reviewing the project, said 'The annually decreasing quantity of water in the London bason is also to be remarked The fall in the level of the wells is, according to credible evidence, about one foot per annum, and there has been a decrease of full twenty feet within the last twenty years Though this gradual fall is certainly not an object of immediate apprehension, as to the total failure of the supply, yet the infinitely more rapid ratio of decrease which would ensue, if the whole metropolitan supply were taken from the same source, must be obvious

"For these reasons we have come to the conclusion that though London is supplied with a considerable abundance of the most salubrious well-water for general purposes of domestic use—yet, that to draw upon the bason for the whole of the supplies by means of steam power is, if not objectionable for other reasons, impracticable by reason of the expense of the many divided establishments which must necessarily be required for the production of 20,000,000 galls per day, which is the generally estimated quantity used in the metropolis"

The Hot Blast at the Butterley Iron Works

For some years after the introduction by Neilson of the hot-blast, there was considerable controversy over its merits One of its advocates was Joseph Glynn, F R S (1799–1863), who was engineer to the Butterley Iron Works, near Derby. In a letter of his published in the *Mechanics' Magazine* of June 27, 1835, he said : "The Butterley Company employ in their mines, coal-fields, blast furnaces, rolling mills, forges, boring mills and steam engine factory, 35 steam engines of all sizes, from 80 inches of diameter of cylinder, and have six blast furnaces, of which four are now at work. The whole of these furnaces are blown with heated air, and the coal, which is admirably adapted for the purpose, needs no cokery, being very carbonaceous The mountain limestone which lies but three miles from the furnace, is used as flux for the ore, which is clay iron-stone. These materials produce a very fine grained cast-iron, remarkably soft and fluid, and at the same time they are equally well adapted to make 'forge pigs' from which are manufactured bars, hoops and boiler plates, of best quality and steam engines . . M. Dufresnoy, M. Perdonnet, and several other Frenchmen of scientific reputation, have visited the Butterley Company's works, with which they have been highly pleased, and have been willing to communicate the valuable information they possess, in return for such as was afforded them here".

Social Research and Industrial Reorganisation

ASSOCIATED with the general satisfaction at the improvement in trade which finds expression to-day, there is a desire to understand, and use to advantage, the factors responsible for the better conditions which prevail It is clear that, on the whole, 1934 recorded a distinct advance over 1933 In most countries unemployment continued to diminish, production to increase and exchanges remained more stable In some countries the belief became current that the depression was already passing into history While, however, it may be fairly said that the world's economic life has been running in smoother and deeper channels, it is still far from having returned to the broad, even flow of real prosperity The imminent dangers of renewed international competition in armaments alone should make even the most thoughtless pause before indulging in extravagant prophecy about the return of an age of prosperity, but there are many other facts which should discourage easy optimism. Not the least of our present perils is that the improvement in trade which has undoubtedly been experienced in Great Britain and elsewhere may be interpreted by partisans as the fruit of policies and methods which impartial investigation might reveal as really hindering recovery.

The annual reports of the director of the International Labour Office provide an expert examination and analysis of the social and economic conditions of the world which assists even the layman to probe the partisan claims with which he is often assailed. Mr. H. B. Butler's latest report* is no exception to the rule. His analysis shows clearly that hopes of a general recovery have not materialised. Recovery is still superficial rather than fundamental. There is still widespread distress and frustration of hope. There is no sign of a general swing-back of the pendulum to prosperity without any basic disturbance of the economic system having taken place and without any serious political consequences having ensued.

There is much indeed in Mr. Butler's survey that is not only highly interesting to scientific workers, but also significantly in line with the conclusions of many among them who have endeavoured to arrive at an impartial opinion on the present situation and the means of recovery Controversy still unfortunately rages round many

* Report of the Director, International Labour Office, Geneva, 1935

questions such as that of public works as a remedy for unemployment, nurtured more by the desire to prove or disprove the value of some economic doctrine or political attitude than by any judgment of the real facts.

If, however, there is one thing which is more and more clearly evident, it is that policies of temporising or dalliance with prejudice rather than facts are not only ineffective but also liable to be disastrous Everywhere fatalistic belief is giving way to the demand for systematic collective action, and Mr. Butler in his survey notes that, in dealing with the problems presented by the depression, those Governments which have adopted unorthodox measures have, on the whole, succeeded better than those which have relied on the traditional processes. Deliberate interference by the State in economic affairs has continued to increase rather than to diminish. Its success appears to be justifying and strengthening the popular belief that by bold, well-conceived steps planned on a sufficiently comprehensive scale, Governments can influence the course of recovery to a very considerable extent.

This growing reluctance to accept the thesis that human agencies are impotent to control the fluctuations of economic fortune is one of the most significant and hopeful signs of the present time Its very existence is a psychological element in the general situation which cannot be ignored In addition, it represents not merely confidence in the ability of man to regain control over events, but also a willingness to accept change, to try new methods It is a hopeful sign in itself which permits the co-operation of the scientific worker and the application of the scientific method to these difficult problems There could be no greater tragedy than for the slight recovery which has been experienced in the last year to blind us to the necessity for fundamental investigations and perhaps changes of policy and methods, if the full recovery and the alleviation of the hard core of unemployment and general distress, which are undoubtedly within our powers, are to be secured.

Against this very real danger, one of the surest safeguards is the extent to which recent and more fundamental attempts to modify and adapt the old economic structure to meet the new conditions have been inspired in the main by social considerations. It is not merely that Governments are expected to devote the same energy, ingenuity and attention to the provision of the elementary needs of feeding, clothing and shelter on a civilised scale as to the promotion of air communications, wireless services and elaborate systems of national defence Questions of organisation of industry, hours of work and the like are judged more and more from a social point of view than from that of financial or technical efficiency alone.

To these social implications, Mr. Butler, in the report to which we have referred, directs special attention In commenting on relief of unemployment, he points out that the failure of relief, while warding off actual starvation, to prevent progressive under-nourishment and demoralisation of individuals and families where unemployment is of long duration, is leading to an increasing demand for adoption by the State of energetic measures to create work, whether direct or indirect. His reference to the devastating effect of juvenile unemployment is pertinent in relation to the Jubilee Trust Fund recently inaugurated in Great Britain For juvenile unemployment, relief affords no solution. "No social problem is of more vital importance and it may safely be said that money saved by ignoring the dangers of intellectual, physical and moral deterioration to which the young unemployed are exposed represents the worst and most short-minded form of national economy".

This growing insistence on the importance of the social factor coincides with a wider recognition of its importance on the part of scientific workers themselves. Julian Huxley has suggested that the main trend of post-War thought, where not merely pessimistic or destructive, is in the direction of science tempered by humanism; and the refusal of public opinion to consider the improvement of production, the growth of retail sales or the appreciation of securities as in themselves satisfactory unless accompanied by a corresponding reduction of unemployment, is paralleled by growing attention to the social factors on the part of scientific workers, whether as affecting the direction or conditions of their own work or as a field for further investigation.

It is in fact at last being widely realised that an elaborate mechanical organisation is often a temporary and expensive substitute for an effective social organisation or a sound biological adaptation. The error of confusing efficiency with adaptation to large-scale production is being more and more apparent, and in many fields, organisation and processes are being judged less by their purely mechanical or technical efficiency than by their social consequences in the widest sense. What the product contributes to the labourer becomes as

important as what the worker contributes to the product.

From this point of view the ideal of fitness for a purpose implicit in technology acquires a new significance. The rationalisation of industry is no longer considered merely from a technical or economic point of view The entire social situation must be taken into account. A process which promises higher technical efficiency may indeed be rejected, for example, either because of the untoward disturbances it produces in the State as a whole or because of the risks it involves to the health of the worker. As Mumford suggests in "Technics and Civilisation", "a rational society might alter the process of motor car assemblage at some loss of speed and cheapness to arrive at a more interesting routine for the worker Similarly it would either go to the expense of equipping dry-process cement-making plants with dust removers—or replace the product itself with a less noxious substitute. When neither alternative was practicable it would drastically reduce the demand itself to the lowest possible level".

In this attitude there is essentially no slowing up of progress On the contrary, while the direction of research may be changed, its scope is enlarged. The realisation that industry offers opportunities for creative experience which is social in its processes as well as in its objects gives a new impetus to research over a wide front Such bodies as the National Institute of Industrial Psychology are indeed only faintly foreshadowing the services which they can render, when industry and society are widely permeated with an ideal of efficiency or rationalisation which takes full account of the worker and the social consequences, as well as of the process, the product and the economic return The following out of the principle of economy in its highest and truest sense means that at least as much attention will be paid to the choice of the correct means of avoiding waste of human effort and welfare as to the choice of the appropriate apparatus or raw materials The stress laid upon the problem of unemployment in the midst of the Jubilee rejoicings emboldens the hope that, so far from the partial recovery already experienced leading us astray, there is a growing determination to seek new ways and means, if those of the past prove inadequate to solve this problem and secure the wider distribution of the vast resources at man's disposal, could he but make mechanisation his servant and not his master.

Reviews

The Arachnida

The Arachnida By Theodore H Savory Pp xi+218+8 plates. (London Edward Arnold and Co , 1935) 25s net

THE Arachnida have been unduly neglected by zoologists, having been overshadowed as objects of study by the beauty and infinite variety of the insects. The study of the class has been difficult, owing to the scattered literature and the scarcity of several of the forms. Of the ten existing orders, only four are represented in Great Britain, and several of the smaller orders do not reach the confines of Europe. Mr Savory has now given us a generalised account of the class as a whole, for which all zoologists and naturalists will be grateful.

The Arachnida, more than the insects, have attracted the attention of philosophical morphologists, since the days when Strauss-Dürkheim, so long ago as 1829, first pointed out that *Limulus* is an arachnid, and the close resemblance between that genus and the Eurypterida has long been recognised. It is remarkable that of these two primitive groups, *Limulus* has survived, being to-day not only by far the largest arachnid, but also the only marine one, while the Eurypterida, making their first appearance in the Cambrian, attained their zenith in the Silurian, producing such extreme forms as *Stylonurus* of the Old Red Sandstone, which reached the enormous size of ten feet, with very long legs These gerontic characters foretold an early extinction, for the order made its last appearance in the early Carboniferous

In discussing the evolution of the class, the author quotes the theory associated with the names of Ray Lankester and Pocock, according to which *Limulus* and the scorpions were both derived, each through an intermediate link, from the Eurypterida, which in turn, through *Limulava*, came from the Trilobites. In any event, all will agree that the Eurypterida, *Limulus* and the scorpions undoubtedly have a common origin Zittel derives all three from a hypothetical early Cambrian predecessor, reserving the Trilobites as ancestors of the Crustacea But, as the author points out, if by this hypothesis he would exclude the Trilobites from being at the same time ancestor of the Arachnida, he is virtually denying evolution

The critical step in the evolution of the class

was in the Silurian, when they changed from an aquatic to a terrestrial habitat, *Limulus* alone retaining a marine life, with gill-books

Leukart, Hansen and Sørensen, from a study of the breathing apparatus, draw conclusions different from the English morphologists. They regard the Palpigradi and Solifugæ as being the nearest survivors to the primitive type, which, they maintain, was terrestrial, the crustacean characters of *Limulus* being due to convergence.

Mr. Savory prefers to suspend judgment He points out that the Arachnid-Crustacean-Myriapod group of the phylum Arthropoda are all built upon a 21-somite plan, and evolved from a vermiform ancestor, which must be sought in the pre-Cambrian in the *Onycophora*, as Versluys and Demoll have sought to establish

As to the genetic relationship within the class, the one point on which there is general agreement is that the ten existing and seven extinct orders cannot be arranged in an ascending series. It is also accepted that the scorpions are the most primitive terrestrial forms, with the Pedipalpi and Solifugæ very close. The spiders are the most highly specialised, and the Acari are certainly degenerate, with the Opiliones intermediate. The system adopted by the author is that drawn by Pocock, with slight modifications, as the rejection of the Trilobites, which are now generally regarded as Crustacea, the inclusion of the fossil orders, and the rejection of the Pantopoda, Pentastomida and Tardigrada From the discontinuous relationship between the orders, Mr. Savory draws the conclusion that "the hypothesis of an evolution taking place by slow successive degrees is not in accordance with the facts".

One feature of the Arachnida which makes them so attractive is their conservatism, the survival of such primitive and ancient forms as *Limulus* and the scorpions, which Ray Lankester has described as "the oldest animal form of high elaboration which has persisted to the present day". Scorpions first appear in the Silurian, as pioneers of the air-breathers, and were as highly developed by the Carboniferous as they are to-day. Four other orders share the pride of almost unaltered descent from Palæozoic days, the Opiliones, our familiar harvestmen, the Solifugæ or wind scorpions, and the Pedipalpi.

The most surprising group in the class is the Ricinulei or Podogona. These extraordinary little creatures, which have never evolved eyes, appear to have scarcely any sense organs and carry their genitalia in the tarsi, were first discovered in the Carboniferous of Illinois in 1837. In the following year Guérin described a living specimen from West Africa. Now there are six fossil and thirteen living species known, but the astonishing thing about them is that to-day, almost a century after their discovery as living creatures, only thirty-two specimens are known to exist. As the author says, each specimen seen by man is something of a historical event.

Mr. Savory's concern is not confined to the taxonomic and evolutionary aspect of the study. In the text he brings out many points of the highest interest, with a literary skill unusual in purely scientific works. He points out that the time has come for arachnology to possess the same unity and status enjoyed by entomology, and that the day has come for a science of comparative arachnology He gives a series of essays, interlarded as 'Excursus', which well repay reading, and a clear summary of the structure, classification and evolution of the class, the habits of the creatures and their behaviour, in which he explains, for the non-specialist, modern views on instinct, reflexes and tropisms, with an indication of the work that has been done on their courtship, mating, dispersal, distribution and manner of life To make the work complete, he includes an outline of those groups which have been doubtfully associated with the Arachnida, such as the Tardigrada, Linguatulidæ and Pycnogonidia, with essays on laboratory work, the economic aspect, and an outline bibliography M. B

Theoretical Materials and Experimental Structures

(1) *Theory of Elasticity*. By Prof. S. Timoshenko. (Engineering Societies Monographs.) Pp. xvi + 416 (New York and London: McGraw-Hill Book Co., Inc., 1934.) 30s net.

(2) Department of Scientific and Industrial Research. *Second Report of the Steel Structures Research Committee*. Pp. xviii + 369 + 25 plates. (London: H M Stationery Office, 1934) 7s. 6d. net.

FOUR of the leading engineering institutions of America have engaged in a fresh enterprise in technical literature Selected manuscripts of value to engineers and industry, but of probably limited appeal because of their special nature or treatment, are to be produced in a series entitled "Engineering Societies Monographs". Prof. Timoshenko's volume is the first to be issued and gives a fine impression of the high standard intended.

The author's previous volumes on "Strength of Materials" (reviewed in NATURE, 128, 617, Oct. 10, 1931) dealt with engineering materials in a very thorough fashion, but in the order of development more usual in technical treatises on the subject. The present work on theory is guided largely by the mathematical bases, and in classification and details departs from this common order.

The mathematical method and the engineering method in theoretical development are in direct contrast. The former seeks primarily the most general treatment and formulation, and then particularises to elucidate problems of a class The engineering application is an exercise The latter method uses elementary theory so far as it will go, without greatly emphasising its shortcomings until it ceases to work satisfactorily The practical problem is the main aim; and the elementary methods are quite acceptable so long as they give rational guidance in design They do so in many important lines of study, such as bending theory, but it is the failure of these methods in the more difficult modern problems of construction that renders such a work as the present volume important and necessary to engineers

It has been estimated that 80–90 per cent of the failures occurring in modern engineering construction are due to fatigue. This evil displays itself as a progressive cracking developing from zones of high stress concentration due to form variations or discontinuities, holes, corners and re-entrant angles. The treatment of stress concentration is quite beyond the elementary theory, so prominent in engineering curricula, but the results in practice emphasise the failure of the theory—and the curricula—by the failure of the parts. The experience only slowly affects technical literature, but has certainly dated the older text-books on materials. Prof. Timoshenko has taken a very active part in the investigation of the subject, and he is also to be congratulated on his activities in rewriting its literature

While it is necessary to decry the powers of elementary methods of stress analysis, it must not be supposed that more powerful mathematical methods can always provide full solutions. Investigation on materials and structural forms to-day is a remarkable mixture of analysis by formal elastic theory and by energy methods, by direct experiment; by indirect experiment such as the photo-elastic method; and by the use of analogies such as the soap film, the hydrodynamical and the electrical parallels. Prof. Timoshenko gives all these methods due attention. His book is not a mere array of theoretical developments, but a powerful attack upon, and a careful classification of, all methods aiding the solution of specific engineering applications.

The author's arrangement is of distinct interest Two-dimensional problems are dealt with by rectangular and polar co-ordinates and by the use of the complex variable. There is a general analysis in three-dimensional work with an extensive consideration of torsion and bending, including a careful discussion of analogous methods. Strain energy methods and theorems are adequately presented and there are special and characteristic chapters on axially symmetrical stresses and wave propagation Apart from the last, vibration problems are not considered; and instability problems are not dealt with in this text The wealth of reference, by footnote and otherwise, greatly enhances the value of the book, while it displays the author's scholarship and not infrequently discloses his personal share in the development of the subject.

(2) In Timoshenko's work the methods of theoretical investigation in elasticity are presented in classified array with the problems which they solve, help to solve or hope to solve But when these are gathered together, they cannot be found to include with any confidence in any category the apparently simple column and beam system that, with its connexions and supports, comprises the standard building frame. The method of inquiry into this important structural form initiated by the British Steelwork Association and directed by the Steel Structures Research Committee affords a definite contrast with purely theoretical discussion. It calls for a close and patient establishment and examination of experimental, statistical and theoretical data, with a view to the formulation of comparatively simple design codes. These must avoid highly elaborate calculations and yet allow of reasonably correct assessment of intricate factors such as are created by the interactions of columns and beams through their connexions.

In its first report in 1932, the Committee disclosed its plans for systematic research, and recommended a code of practice incorporating up-to-date ideas and effecting economies in design. The code was a tentative effort at order and scarcely pretended to elucidate fully the problems concerned with the contractions of the structural elements. In this second report now issued, the Committee shows itself mainly engaged on these difficulties, and presents a remarkable collection of data and ideas relevant thereto

The usual assumption of completely rigid joints in built structures is only a simplification in calculation. It is recognised to be untrue. Some slip must occur at the connexions. The amount of this has been variously assumed for different purposes, but the Committee rightly deals with this question as one of the vital matters at issue The procedure followed has included investigation of the actual behaviour of connexions in full-scale experimental frames; the measurement of stresses in actual building frames before and after encasement in concrete; and an elaborate investigation of various forms of connexions and bolted joints

The experimental building frame was described in the first report. Dr. Baker, the technical officer

to the Committee, now presents an interesting report on the results obtained for single-bay and two-bay arrangements, and discloses the surprising fact that quite slight differences of some kind in the connexions result in considerable variations in the stresses. Even with the use of the experimental refinement of a 'torque control' spanner for the joint bolts, discrepancies of a fair amount still existed Dr Faber deals with the tests and stresses in the steel frame structure at the Museum of Practical Geology, South Kensington, while Prof Batho and others discuss very fully experimental and analytical work on joints, bolts and connexions This last includes interesting and unusual work on bolt stresses and torque control in tightening. In fact the 'torque control' spanner is a surprising but noticeable and recurring feature of this report, and we may be allowed to wonder whether it will ultimately appear in building codes

The report also contains an excellent discussion on analytical methods by Dr Baker, including a treatment of mechanical analysis by models There is a concluding section of distinct importance on the strength of welded joints carried out for the Committee at the National Physical Laboratory and containing valuable results on the hitherto somewhat neglected aspect of fatigue strength. Altogether this report contains a vast amount of vital information It requires careful study, but the study will be well repaid

Electrokinetic Phenomena

Electrokinetic Phenomena and their Application to Biology and Medicine By Dr Harold A Abramson (American Chemical Society, Monograph Series, No 66) Pp 331 (New York: The Chemical Catalog Co, Inc., 1934) 7.50 dollars.

DR ABRAMSON'S monograph is planned partly on historical principles. In his first chapter he records the discovery of the phenomena classified by colloid chemists as capillary-electrical or electrokinetic, namely, the flow of fluid past a wall and the movement of a small particle caused by an electric current, and the converse phenomena, referred to as the flow potential, set up by the movement of liquids through porous diaphragms. In the second chapter, he describes the correlation between these phenomena and potentials at surfaces, worked out by Helmholtz and by Smoluchowski. More recent work, based on the conception that an ion atmosphere is present at the surface, due to Gouy and to Debye and Hückel, is recorded in the fourth chapter.

Experimental methods, including the apparatus used by Abramson in his studies of particles coated with proteins, are described in the second chapter, and the remaining chapters describe experiments on proteins, inert surfaces, inorganic and organic surfaces, gases, blood cells, bacteria and related systems From some points of view, an arrangement in which the simpler systems are dealt with first might be preferable, but there are certain advantages in considering the proteins first In the words of the author, "Although the proteins are complicated from the point of view of their chemical structure, from another aspect they are less complicated than any other surface to be discussed here, for the reason that the average electric charge Q per dissolved molecule can be determined by a thermodynamic method This charge so determined, can serve as a reference with which the validity of the theories of electrokinesis can be tested".

In the account of the thermodynamic method, evidence is recorded in favour of the view that protein chlorides are fully ionised in dilute solutions, and it is concluded that the charge can be calculated from the acid or base bound, as measured by the hydrogen electrode It is shown that such titration curves can be superposed on curves showing the relationship between mobility and pH value, recorded by Tiselius and by other investigators. These observations support the thesis that, in some respects at least, the protein surfaces are particularly favourable for experimental investigations It may be noted that the observations of Freundlich on inorganic surfaces showed no correlation between electrokinetic and thermodynamic potentials.

In a field complicated by many unknown factors, the discovery of simple relationships is of great value, but in a review of the work it is perhaps advisable to point out that there are certain qualifications of the conclusions drawn by Abramson, which have not been stated in his book In the first place, the amount of acid or base combined with a protein at a given pH is not independent of the amount of neutral salt present, as shown by Sørensen, Linderstrøm-Lang and Lund.

In the second place, it may be noted that since the publication of this book, additional evidence concerning the validity of the author's method has been obtained by comparing measurements of titration curves and valences calculated from membrane potentials, and it would appear that the results calculated from titration curves may be subject to appreciable corrections

Although differences of opinion may be held on certain points, there is no doubt that Dr. Abramson's book should advance the study of electrokinetic phenomena, as he has brought together recent work on the physical theory of the double layer, and experimental data obtained in the fields of chemistry, biology and medicine

Short Notices

Structural Design in Steel By Prof Thomas Clark Shedd. Pp ix+560 (New York John Wiley and Sons, Inc.; London Chapman and Hall, Ltd, 1934) 25s. net

THE professor of structural engineering in the University of Illinois, recognising the impossibility of adequately covering the whole field of structural design in a single volume, has confined his attention to the fundamental principles of steel structures, and has produced an eminently practical manual, interspersed with numerous worked-out examples of calculations, which will be of considerable assistance to the draughtsman, the designing engineer and the student.

Commencing with an introductory chapter of a general character, the book goes on to discuss structural types and framework, the design of beams and girders, tension and compression members, and connexions. Then follow two chapters dealing with the design of structures as a whole one on buildings, primarily of the industrial type, and the other on bridges, both roadway and railway. Both chapters include detailed sets of illustrative calculations of a practical character Since fusion welding is now widely used as a means of jointing, and is not so adequately standardised as the older forms, the author has discussed the subject in a special chapter. Three appendixes, covering general specifications in design, based on standard American practice, form a suitable conclusion to the volume, which is clearly and excellently produced, particularly as regards the numerous diagrams and sheet calculations. The illustrations include a number of photographic views of structures in the United States B. C.

Food and Health. By Prof. Henry C. Sherman Pp x+296. (New York. The Macmillan Co, 1934) 10s. 6d. net.

PROF H. C. SHERMAN, the author of several scientific books on food and nutrition, has now written a short popular account. A clear description of the caloric requirements of adults and children is summarised in a useful table. Regarding the daily amount of protein, about which there has been so much controversy, Sherman concludes, from direct experimental data, that 44 gm. a day suffices for an adult; for children relatively more, at the figure of 10–15 per cent of the calories. The nutritional responsibilities assigned to the proteins belong rather to the mineral elements and vitamins. The chapters on the vitamins are short. The optimal amounts of each vitamin are four or five times those found as minimal. There are tables, needing corrections, showing the distribution of the vitamins in foods.

A chief feature of the book is the discussion of the supply of mineral salts. Every human being, says Sherman, is born calcium-poor, but iron-rich. The intake of calcium and also of phosphorus must therefore be relatively greater than that of other body-building foods, the daily amounts are given. Attention to mineral salts and vitamins will more surely lead to buoyant as distinguished from merely passable health. A long list of diets shows how the low protein consumption with high calcium and phosphorus (mainly from milk, of which a quart a day is recommended for children) and ample vitamins can be secured The book merits every attention.

The Human Gyroscope: a Consideration of the Gyroscopic Rotation of Earth as Mechanism of the Evolution of Terrestrial Living Forms. Explaining the Phenomenon of Sex: its Origin and Development and its Significance in the Evolutionary Process By Arabella Kenealy. Pp. v+313+16 plates. (London. John Bale, Sons and Danielsson, Ltd, 1934.) 12s. 6d. net.

MISS KENEALY attempts to show that Newton and not Einstein is right; that Einstein's theory contains no creative principle Her predominant idea is that the development of biologic forms is due to the gyroscopic influence of rotation, acting by way of what she terms the "Great Potter's Wheel of Evolution". She maintains her thesis with a bewildering mass of evidence from many sources, but few of the conclusions she arrives at by skilful argument will bear critical examination While respecting her convictions and impressed by the advocacy of her case, most scientific readers will remain unconvinced.

Aircraft Progress and Development By Capt P. H Sumner Pp. xiv+295 (London: Crosby Lockwood and Son, 1935) 25s. net

THIS volume claims to be "a world picture of progress in Aviation" If the author had confined himself to that conception it would have been an interesting book of the historical record type, that should find a place in every library collection directed toward that end. The illustrations and their descriptive matter are exceptionally complete, and must be the result of a very considerable labour in collecting and collating them The pictures themselves are discreetly chosen and well reproduced The book fails badly when it attempts to give scientific and technical explanations in too small a compass. Compression of technical statements has led the author into both ambiguities and errors.

Geschichte der physiologischen Chemie. Von Dr. Fritz Lieben. Pp. ix+743. (Leipzig und Wien: Franz Deuticke, 1935.) 20 gold marks.

THIS is a somewhat lengthy historical account of the development of the subject between, or common to, chemistry and physiology, which is now called biochemistry. The story is told at first in connexion with individuals; later it has relation to function and to individual chemical groups. Few will find the leisure to read so long a work, but the author and subject indexes make reference to particular problems easy.

The Geological Survey and Museum

THE new building for the Geological Survey and Museum which has been erected on the west side of Exhibition Road, South Kensington, London, S.W.7, stands in a middle position between the Victoria and Albert Museum, the Science Museum and the British Museum (Natural History). The site which it occupies is part of the ground acquired by the Royal Commissioners of the 1851 Exhibition, and was chosen for this purpose by the Bell Committee (1912). The new Museum (Fig. 1) is linked to the Science Museum by a series of corridors over an arched gateway; at some future time, the Natural History Museum may be extended to the east, and the new buildings will probably join up with the Geological Survey and Museum on its south side.

The building was designed by Mr. John H. Markham, of H.M. Office of Works. Its eastern front, facing Exhibition Road, is of classical design, with a Corinthian colonnade, and has been described by competent judges as one of the most successful recent classical buildings in London. The front archway and part of the north side is of Portland stone, but the rest of the building is of brick with stone sills and courses. The shape is a simple rectangle 312 feet long by 100 feet wide and 95 feet high. The Museum occupies the front part of the building while at the rear are the Survey offices, laboratories and library.

Large, metal-framed windows occupy almost the whole of the sides of the building, and in order to secure as much light as possible the amount of dead wall has been severely cut down. The result is that the interior is very well lighted. The general arrangement is that of a central court or well, forty feet wide, lighted from above by a glazed, arched roof, and side galleries, thirty feet wide, lighted by the windows in the walls. The exhibition space comprises a main floor and two galleries, and there are large staircases at each end of the Museum. The galleries are supported on rectangular steel pillars, and the whole building is steel framed, with concrete floors; it is as nearly fireproof as possible. In the Museum there are no partitions, separating the interior into rooms, but the whole structure is open. The

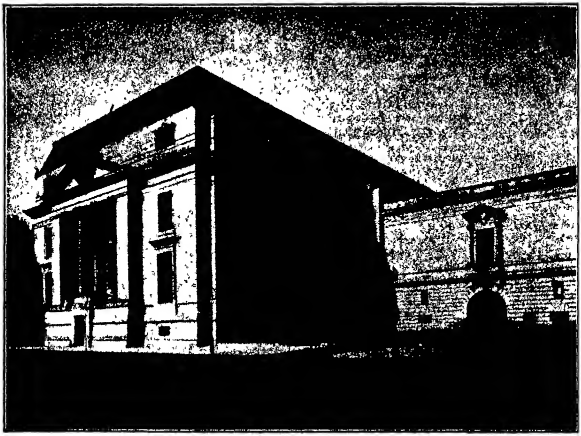

FIG. 1 Geological Survey and Museum, South Kensington.

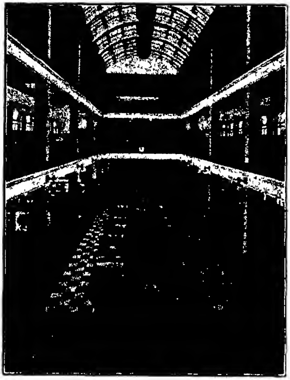

FIG 2. General view of interior, showing the central court and two exhibition galleries

entrance hall and eastern staircase are lined with polished marbles, but in the rest of the building there has been no attempt at decoration, and the architect has relied principally on proportion and symmetry to obtain his effects.

The transfer of the collections from the old Museum in Jermyn Street was completed by the end of October 1934, and the old Museum is now being demolished The Geological Survey and Offices have been occupied, and the library has been open to the public since November. Considerable progress has been made in the work of arranging the exhibits, and when the new Museum is opened on July 3 by H.R.H The Duke of York, it will be found that all the floors are covered with displays, which are practically entirely new and totally different from those which were shown in the Jermyn Street Museum.

The main floor (Fig. 2) has been devoted to an exhibition of the introductory principles of geology with the object of interesting the general public who have no special knowledge of the science A very fine display of gems and semi-precious stones is placed in the centre court To avoid the disturbing effect of reflections from the roof, the glazed cases have curved tops. they are also provided with artificial illumination Such minerals as diamond, ruby, sapphire, emerald, topaz, zircon, peridot and lapis lazuli are shown on one side, and on the other onyx, agate, jasper, opal, chalcedony, labradorite and adularia

The side spaces under the galleries are divided up into bays by means of vertical screens about seven feet high These screens are covered with photographs showing scenes of geological interest. Each bay illustrates a subject, such as glaciers, earthquakes, volcanoes, marine deposits, river action, rock structure, weathering, the action of plants or the origin of coal In the table cases a very complete series of specimens, fully labelled, provides examples, mostly of British origin Each table case also has a medial screen with coloured sketch maps, sections and diagrams The principle followed has been not to show too many specimens, but to see that all are as typical as possible and to explain their meaning fully and clearly. On this floor also there is a group of dioramas representing picturesque scenes of geological significance, such as the Needles and Alum Bay (Isle of Wight), Edinburgh as seen from Braid Hills, the Avon Gorge (Bristol), Lulworth Cove, Cheddar Cave and Vesuvius (in eruption) It is intended that on this floor the exhibits will interest and attract visitors who have no special knowledge of geology.

In the first gallery, the object aimed at is to

FIG 3. East end of first gallery, showing division by screens carrying photographs.

show the geology of Great Britain For this purpose the country has been divided into areas or regions that have a definite geological and also geographical identity Examples are London and Thames Valley, the Weald of Kent, Devon and Cornwall, South Wales, North Wales, Hampshire Basin, Northern Highlands of Scotland, Central Valley of Scotland Each region is fully illustrated with maps, photographs, sections, rocks, fossils and minerals A special descriptive handbook of each province is being written by an expert geologist who knows the district thoroughly

In the second gallery, the exhibits are intended to explain the origin of the principal metals and the economic application of geology. In the table cases are selected specimens of the ores of iron, lead, zinc, copper, manganese, etc , and also a full exposition of useful non-metallic minerals such as talc, gypsum, china clay, rock salt In special cases there is a large series of British building stones, and such subjects as roadstones, slates, cements, brick clays and asphalts will also have space assigned to them

One of the most important features of this Museum is the accommodation provided for research material and for investigators who wish to work on the Survey's collections. In the top of the Museum there is a third gallery (not visible from the main floor) with about 16,000 feet of floor space, excellently lighted. This is to be reserved entirely for cabinets containing those specimens of minerals, rocks and fossils that are of special interest and importance, and likely to be consulted by scientific experts There is also in the basement of the Museum a large store containing drawers filled with material of less importance which requires to be preserved not for its inherent interest but rather as a record on which statements in the Survey memoirs are founded

The new Museum and Offices are nearly three times as large as the building formerly occupied The cost of the building was approximately £220,000 The old Museum in Jermyn Street has been let on a building lease by the Commissioners of Crown Lands at a yearly rental of £11,000

Clinical Science within the University

IN the Huxley Lecture delivered at the University of Birmingham on March 14 and published in the *British Medical Journal* of March 30, Sir Thomas Lewis made a strong appeal on behalf of the recognition of clinical science, which may be regarded as an answer to the presidential address of Sir Frederick Gowland Hopkins on "Clinical Medicine and Science", a survey of which appeared in NATURE of December 8, 1934 (p 867). In his address Sir Frederick expressed his conviction that the scope for really controlled experiments applicable to the human body was limited, and he deprecated the growing tendency to distribute the funds provided for medical research in the endowment of the clinic at the expense of biological science, and particularly biophysics and biochemistry.

Sir Thomas Lewis started by quoting with approval the declaration made by Sir James Paget sixty-five years ago, that "clinical science has as good a claim to the name and rights and self-subsistence as any other department of biology" ; but he used the term "clinical science" in a wider sense than Paget, who confined it to researches on living man, by defining it as "the branch of knowledge that centres upon diseased human beings, but which also includes relevant parts of the allied sciences". The field of clinical science therefore should include physiology, morbid anatomy and experimental medicine.

Sir Thomas emphasised the point that clinical science is not identical with clinical medicine and clinical surgery, and drew a distinction between the science and art of medicine ; but he maintains that a university must possess a strong scientific department inspired by direct clinical interests

As regards experimental work, Sir Thomas declared that every remedy employed to-day is the result of direct experiment on man, as is best exemplified by vaccination, antiseptic surgery and general anæsthesia Only safe and beneficial experiments are justifiable, and no experiments should be carried out except with the patient's consent. In Sir Thomas's opinion, too many experiments have been and are still being performed , a reduction in their number, and their conduct on a stricter, safer and more productive basis are desirable.

The first requirement of a university department of clinical science is an out-patient department and an in-patient service sufficient to supply ample material for research and teaching, the size of the departments to be decided partly by local conditions and partly by the activities of the professor and his assistants. While admitting that clinical science is essentially a laboratory science, Sir Thomas does not think that the laboratory should be a place reserved for animals. On the contrary, he maintained that laboratories for the

examination of patients as well as of animals should be close to the clinical services, and even directly attached to the ward or out-patient department

Although many valuable discoveries may still be anticipated from those actively engaged in the practice of medicine and surgery, Sir Thomas expressed his conviction that in many directions advances may more readily come from men who are able to give their whole time to research, unhampered by routine duties Appointments for clinical research are therefore required, and no more suitable place for such appointments could be found than within a university, where persons engaged in research would enjoy the stimulus derived from teaching and find a congenial atmosphere.

Sir Thomas then passed on to the subject of the medical education of to-day, in which, as is generally agreed, he holds there are grave defects The curriculum is overloaded not only by the preliminary sciences, including anatomy, physiology and general pathology, but also on the clinical side

The plan suggested by Sir Thomas Lewis as a remedy is as follows There should be a first course consisting of the outlines of human anatomy and physiology, with special stress laid on what is immediately applicable to the study of disease The second course, which would not be compulsory for all medical students but would be suitable to a science degree or to those who intended to take up physiology, pathology or clinical science as a career, would be one of more advanced physiology. The third or final course would consist partly of general and practical instruction along existing lines, emphasis being laid on all that is essential to general practice The teaching should be mainly concerned with common diseases and remedies of proved value and ready application The outlines of clinical science should be included in this course, which would be taken by all medical students, but higher examinations would be held by the Royal Colleges and possibly by the universities, and there might be room for a university degree in clinical science for those who proposed to adopt an academic career

As to the final stage of the student's preparation for medical practice, Sir Thomas granted that the best teacher is the man in active practice, who not only understands disease and its treatment in detail but is also able to manage sick people and their friends These accomplishments, however, do not qualify the teacher for the post of university professor in clinical science, whose duties should rather be to deal with the principles and problems of clinical science, and with the patients only to exemplify specific points The former would include the causes of disease, the principles of hereditary transmission of human diseases, the reaction of man to his environment, physical injuries and chemical poisons, the meaning and effects of infection, the significance of sexual, racial and other predispositions to disease, and the origin of new growths in man

In conclusion, Sir Thomas repeated that it is largely within the power of the universities to establish clinical science on the same basis as the allied sciences of physiology and pathology, as distinct from the practical art of medicine.

British Chemical Abstracts

ALMOST exactly eight years ago, the appearance of the first annual index volume, covering the whole of the abstracts in pure and applied chemistry prepared and published under the direction of the Bureau of Chemical Abstracts during 1926, afforded us an opportunity of referring appreciatively to a scheme which has since proved a remarkably successful co-operative enterprise.

The Chemical Society, which since 1871 had undertaken the task of supplying abstracts of papers dealing with pure, physical, inorganic, organic, analytical, mineralogical and biological chemistry, and the Society of Chemical Industry, which had similarly surveyed applied chemistry since 1882, had for many years maintained mutually helpful contact between their respective abstracting organisations; in 1924, however, these two Societies united in establishing the Bureau of Chemical Abstracts, charging the new body with the task of controlling both the preparation and the publication of abstracts in all branches of pure and applied chemistry, and of securing such unification as might prove practicable By the end of 1925 their efforts had been so far successful that consent had been secured to a common format for the two sections, known as British Chemical Abstracts *A* and *B*, respectively, a considerable amount of overlapping material which had previously appeared in somewhat different forms in both sections was eliminated, and the publication of an annual index envisaging the whole range of pure and applied chemistry was undertaken A few, of course, shook their heads disapprovingly

at this breach with tradition, and there was some regret—admittedly largely sentimental—at the disappearance of the familiar octavo format, but experience has amply demonstrated the wisdom of the decisions then taken, and, moreover, both American and French chemical abstract publications have since joined the ranks of the 'double column quartos'.

The organisation set up by the Bureau immediately on its establishment had by that time proved to be operating smoothly and efficiently, and the editor, specialist assistant editors, abstractors and indexer settled down to a task of annually increasing magnitude with the firm intention of making *British Chemical Abstracts* the world's best journal of its kind While there is no means of taking the exact measure of their success, there can be little doubt that, despite the need to trim canvas on occasion the better to ride out financial storms, the Bureau and its staff have provided the English-speaking world with an abstract journal which for accuracy, conciseness, promptitude, relevance and catholicity can fairly claim a place certainly not less honourable than that of any other such journal in any language.

During the past five years, there has been proceeding, concurrently with, and independently of, the preparation of the annual joint indexes, work which has now borne fruit in the completion of a collective index covering the period 1923–32*. This publication, which so far as the Chemical Society is concerned is a continuation of a series of collective indexes dating from 1841, and so far as the Society of Chemical Industry is concerned includes the abstracts published independently in that journal in 1923, is a quarto production of some 2,100 pages referring to authors and 1,766 pages referring to subjects; it has been estimated that the number of entries must considerably exceed half a million In order to ensure homogeneity it was found necessary to re-index the abstracts in applied chemistry published before 1926, for in the corresponding annual indexes a somewhat different system had been employed. Moreover, the varying spelling of countless Russian, Indian and Japanese authors' names has been standardised so far as possible, although in some cases the decision has necessarily been purely arbitrary; for although the transliteration of Russian characters is consistent when carried out according to the Bureau's scheme, the frequency with which Russian authors publish in other languages leads at times to their names being transliterated almost out of recognition. Such complications and obscurities as might arise from changes in nomenclature during the period under review, from inadequate identification of authors by their surnames alone, and from the massive entries attributable to the largest industrial firms, have been foreseen and avoided so far as is possible.

In the 'author index', series papers by the same author or authors are collected under one main title, with the years and pages placed after the sub-titles at the end of the entry. The general arrangement of the entries is described in the explanatory notes The volume contains a greatly extended list of radicals, whilst a new and welcome feature is the chart indicating the numbering of positions in ring systems

Could scientific achievement be measured in terms of the weight and volume of an index, there would be ample cause for satisfaction on the part of even the most diligent among the workers in this ten-year period. But the mounting figures which record increases in the number of chemical abstracts published annually still reflect a rapid rate of increase in the volume of new material which finds its way into the periodical and patent literature. Figures, of course, can be made to prove almost anything; but an increase from 25,500 in 1932, the last year of the decade, to 29,400 published in 1934 is perhaps sufficient evidence for the assumption that the production of decennial indexes in future will be an even heavier task The corresponding annual indexes—that for 1934 has just been issued—occupy 578 and 692 pages, respectively.

Provocative, or perhaps merely vacuous, statements regarding the desirability of calling a halt in the publication of chemical literature are still heard; such retrogression is clearly impossible; but on the other hand the desirability of brevity and precision in scientific publications cannot be too insistently urged So far as abstracts play a part in maintaining the march of progress, we can profitably repeat what we have said before that since the rate of advance in any branch of knowledge so largely depends on an adequate acquaintance with the experimental results and theoretical views forming the starting point of any new research, the efficiency of the abstracting and indexing service is a matter which closely concerns every investigator, teacher and student. The success attained by the Bureau of Chemical Abstracts is a demonstration of what can be done when interested parties pool their resources, and it should encourage co-operation over an even wider field.

* Collective Index of British Chemical Abstracts. (A) Pure Chemistry and (B) Applied Chemistry, 1923–1932, including the Abstracts published with the *Journal of the Chemical Society* and the *Journal of the Society of Chemical Industry*, during 1923–1925 Part 1: Index of Authors. A—K. Pp. 1092. L—Z. Pp. 1093–2101. Part 2: Index of Subjects. Pp. 1766. (London: Bureau of Chemical Abstracts, 1935.) £8.

Obituary

Sir Robert Blair

We deeply regret to record the death, which occurred on June 10, of Sir Robert Blair, Education Officer of the London County Council from 1902 until 1924. Born at Wigtown in 1859, he became a pupil teacher at the Garlieston Public School and later went to the University of Edinburgh, where he took his degree in 1880. He joined Aske's Hatcham school in 1882 and, while teaching, secured the London B.Sc. degree There followed appointments as head of the Cheltenham School of Science and Technical Institute, Inspector of Science and Art, and Assistant Secretary for Technical Education (in Ireland). In 1904 he was appointed to the London County Council Among the honours which came to him, in addition to his knighthood, were the Order of the Crown from the King of the Belgians, the LL.D. from his old University, an honorary fellowship of the Royal Society of Arts, and a fellowship of King's College, London He was president of the Association of Directors and Secretaries for Education in 1914, and president of the Educational Science Section of the British Association in 1920

It was in London that Sir Robert Blair performed the great tasks which made him famous as an educational administrator Under his direction the present education system was shaped In particular, the new organisation called for by the Education Act of 1918 gave him a great opportunity of demonstrating his powers of organisation.

Sir Robert's special interest in technical education was well known, and it was continued and deepened after his retirement Appointed as the British Association's representative on the Emmott Committee of Enquiry into the Relationship of Technical Education to Industry, he became a member of the executive committee responsible for preparing the report and, following the death of Lord Emmott, carried out the duties of chairman.

Sir Robert's vision of the future was broad, and it was ever present in his work. "Life," he said, "has been extended. The engineer, the chemist and the medical officer have broadened the basis, protected our food supply, and safeguarded the public health . . . Science has given us a new era." That was his attitude, and it goes far to explain his success as an administrator.

Prof. W. E. Soothill

The death of the Rev. W. E. Soothill, professor of Chinese in the University of Oxford, which took place on May 13 at Oxford at the age of seventy-four years, will be widely regretted.

William Edward Soothill was born at Halifax, and after a short term in a solicitor's office became a missionary. He went out to the Wenchow district of China in 1882, and within a short period had acquired a knowledge of Chinese which won the respect of Chinese savants. He became exceedingly active in the promotion of teaching and training institutions and of preaching stations. He also translated the New Testament into Wenchowese, and made a translation into English of the Analects of Confucius The scene of these early labours is commemorated in "A Mission in China". This narrative, however, did not appear until 1907, the year in which the scope of his educational activities was much enlarged by his appointment as president of the Imperial University of Shansi, newly founded by Timothy Richard. His success there encouraged him in the endeavour to promote a university for the whole of China; but his plans, when in course of active preparation by a committee at Hankow of which he was chairman, were interrupted by the revolution and the outbreak of war.

Soothill's services to China in England and France during the War were recognised by the award of two Chinese decorations. In 1920 he was appointed to the chair of Chinese at Oxford. By this time it was recognised that he was the foremost Sinologist of the day He became a member of the governing body of the School of Oriental Studies in London, and in 1926 was a member of the delegation to China in reference to the settlement of the Boxer indemnities

Prof Soothill was the author of a number of scholarly works on China and Chinese, including "The Student's Chinese Dictionary", "The Three Religions of China", "China and the West", "A Short History of China" and "The Lotus of the Wonderful Law". His daughter is the widow of Sir Alexander Hosie, and is also known as a writer of authority on aspects of Chinese life and culture.

Mr. D. N. Dunlop, O.B.E.

Mr D. N. Dunlop died on May 30 after a short illness. He was born in Ayrshire, Scotland, in 1868, and served his engineering apprenticeship in Glasgow. After experience with the Westinghouse Company, he became in 1911 the first organising secretary of the British Electrical and Allied Manufacturers' Association (B.E.A.M.A.) and in 1917 his post was renamed Director. He held this position until his death. He took an active part in the foundation of the Electrical Research Association and of the Electrical Development Association.

While Dunlop rendered great and enduring services to the British electrical industry, it is chiefly as the founder of the World Power Conference that he will be remembered in wider circles Not many years after the War, he conceived the idea that engineers and men of science, whose inventions had been so powerful in destruction, should lend their great talents in the rebuilding of the world. He succeeded in enlisting the support of the Council of the B.E.A.M.A., which ensured the necessary financial backing, and on June 30, 1924, the Prince of Wales opened the first World Power Conference.

Dunlop, from the beginning, had the hope that a permanent organisation would grow out of the first World Power Conference. But it was not his intention himself to make a proposal to this end. In the event, all the countries which participated united to demand that the work begun in 1924 should continue and, as is well known, during the past eleven years the second plenary World Power Conference has been held in Berlin and sectional meetings in Basle, London, Barcelona, Tokyo and the Scandinavian capitals, while the Chemical Engineering Congress of the World Power Conference will take place in London next year

The World Power Conference has, under Dunlop's guidance, become a highly important international body with forty-nine member-countries and a central office in London. But from the beginning he envisaged something much more than a technical organisation of the producers and consumers of power and fuel. He saw in it the meeting-place between scientific workers and engineers on one hand, statesmen and economists on the other. He placed an even higher value upon the opportunities for personal encounters which the World Power Conference provided than upon the great technical results already enshrined in more than forty volumes of transactions

---

WE regret to announce the following deaths:

Colonel W. C. Blackett, past president of the Institution of Mining Engineers and of the North of England Institute of Mining and Metallurgical Engineers, on June 13, aged seventy-five years

Mr W. S Franks, who, for twenty-five years, was in charge of the Brockhurst Observatory, East Grinstead, known for his work on the colours of stars, on June 19, aged eighty-four years.

News and Views

Award of the Albert Medal to Sir Robert Hadfield, Bt., F.R.S.

THE Albert Medal for 1935 of the Royal Society of Arts has been awarded, with the approval of the president, H R H. the Duke of Connaught, to Sir Robert Hadfield "for his Researches in Metallurgy and his Services to the Steel Industry". The Society's Albert Medal, its premier award, is given annually "for distinguished merit in promoting Arts, Manufactures or Commerce". It commemorates the work for the Society of the Prince Consort, who for eighteen years was its president, and to whom the success of the Great Exhibition of 1851, organised by the Society, was largely due. Awards are made irrespective of nationality, and the list of former recipients of the Medal includes the leading men of science, inventors and other benefactors of humanity Seventy-five awards have now been made, of which nineteen have been to workers outside Great Britain The first Albert Medal (1864) went to Sir Rowland Hill, for his reform of the postal system of Great Britain In 1866, Michael Faraday was the medallist, and later recipients have included forty-one ordinary fellows of the Royal Society and nine foreign members. The other metallurgists of the distinguished company which Sir Robert Hadfield now joins are Bessemer, Siemens, John Percy and Sir Isaac Lowthian Bell.

The Abbotsbury Swannery

HOWEVER patriotic and air-minded we may be, however much alive to the urgent necessity governing the general policy of the Air Ministry at this particular moment, the proposal to set up an aerial machine-gun practice ground in the very middle of the "Fleet" alongside Chesil Beach in Dorset, was bound to call forth the protests which it has already done in consequence of the near neighbourhood of the famous Abbotsbury Swannery. Not unnaturally, those informed members of the community who are well qualified to realise the very regrettable consequences which are bound to result, have attempted to make their influence felt One of the most important would be the all too frequent disturbance of the swans on their very localised winter feeding ground. Founded in all probability in 1044 by the monks of the Benedictine Abbey of Abbotsbury, Lord Ilchester has stated recently in *The Times* (June 18) that the first references to the swannery which he has been able to discover are to be found in the Court Rolls of the Manor, 16, Richard II (A D. 1393), and there are many others, including disputes about ownership in the time of Queen Elizabeth. The actual number of swans forming this *perfectly natural colony of wild birds* varies around eight hundred It is, therefore, not only historically and biologically of very considerable interest, but also in all probability it is the largest swannery in Europe at the present moment. Associated with it there are other birds and plants. It has been stated in defence of the proposed target practice ground that birds soon get used to aeroplanes and noise That is no doubt true; but is not the point The vital objection is the ploughing up of their feeding ground by missiles. If the choice of such a locality is really a matter of urgent necessity, it seems altogether deplorable.

Maintenance of Life in Isolated Animal Organs

To study the functions of an organ under well-controlled conditions frequently necessitates its removal from the body in order to avoid influences reaching it from other tissues, which it may not be easy to control. It is difficult, however, to maintain the isolated organ in a condition even approximating the normal. One of the greatest advances was made by Knowlton and Starling in 1912, with the introduction of the 'heart-lung preparation'. This consists of the lungs—artificially ventilated—and heart

of an animal, and pumps oxygenated defibrinated blood round an artificial circuit, which may include one or more different organs; the latter are thus perfused with blood under conditions approximating the normal. The preparation, however, only lasts for a few hours. It is reported in *The Times* of June 22 that Dr. Alexis Carrel and Colonel C. A. Lindbergh, the well-known American airman, have devised, at the Rockefeller Institute for Medical Research, New York, an apparatus by means of which isolated organs can be kept alive, even growing, for prolonged periods.

IN this apparatus, the organs are removed aseptically from the dead animal together with surrounding tissues, arteries, veins, nerves and lymph vessels: all are kept constantly protected with gauze pads soaked in Dakin's solution. The perfusion fluid consists of blood serum or of solutions containing protein-split products: a small amount of phenol red is added to act as an indicator of the metabolic activity of the organ or of the occurrence of bacterial infection. The air supply, kept in contact with the perfusion fluid, contains 40 per cent oxygen and 3–4 per cent carbon dioxide. The apparatus is kept in an incubator at body temperature. The organs so far kept alive in this manner have included thyroid gland, ovary, adrenal, spleen, heart and kidney, obtained from adult fowls or cats; an ovary actually grew in size and weight by the addition of new cells and tissues. It is hoped to use the method for the study of the production of hormones by the glands of internal secretion, for the isolation of substances essential to the growth, differentiation and functional activity of these glands and for the discovery of the laws of association of organs. It is also hoped to study diseases in isolated human organs. The success of the method depends principally upon maintaining complete freedom from bacterial infection, and secondly on the use of suitable nutrient fluids, difficulties which Carrel and Lindbergh appear to have overcome.

Antiquities from Tell Duweir, Palestine, 1934–35

THE annual exhibition of antiquities from Tell Duweir (Lachish), Palestine, found by the Wellcome Archæological Research Expedition to the Near East under the leadership of Mr. J. L. Starkey in the course of the excavations of 1934–35, opened on June 24 at the Wellcome Research Institution, 183–193 Euston Road, London, N.W.1. The objects exhibited again illustrate details of culture in the various periods represented on the site, beginning with the extensive prehistoric settlements of the copper and bronze ages and ending with the later Jewish kingdom, when the city suffered the successive onslaughts of Sennacherib and Nebuchadnezzar. Further light is thrown upon the early cave dwellers, and the possible line of development of the localised art reminiscent of Tell el-Amarna, of which evidence was found last year, is suggested by a bone inlay in the form of a head, which seems to be a copy of an ivory original. Another interesting find is an Iron Age burial, which included among its grave furniture a short-handled iron fork with three long prongs. It is reasonable to conjecture that this implement served the priest to extract joints from the offerings-bin of the sanctuary discovered last year. Culturally and historically, however, the outstanding finds are a further example of the early script, resembling that from Sinai, which adds three characters to those known from last year's find, and a series of letters on ostraka, dating from shortly before the fall of the city, now to be identified with certainty as Lachish. This discovery, long eagerly awaited, alone makes the excavation notable. An instructive commentary on the work of the expedition is afforded by a cast of the bas-relief of the siege of Lachish, now in the British Museum, which, coloured and skilfully flood-lit, can be seen in full detail for the first time. The exhibition is open daily from 11 a.m. until 5 p.m., and on certain evenings until 8 p.m., until July 27. A lecture on "The Lachish Letters found at Tell Duweir" will be given by Dr. Harry Torczyner, professor of Hebrew philology in the University of Jerusalem, on Tuesday, July 9 at 5 p.m. Admission to the exhibition and lecture is free by ticket.

The Quetta Earthquake

A CORRESPONDENT of *The Times* (June 24) gives some interesting details about the great earthquake of May 31. The zone of destruction extends from Surab in Kalat State to a few miles north of Quetta. Its length is 130 miles and its width 15–20 miles. Even within this area, its effects were variable. In some parts, they spread over the whole width; in others, they were confined to a narrow line, some villages being untouched, while others were destroyed. Quetta lies in an upland valley, 5,500 ft. above the sea, in which earthquakes are rather frequent. The recent shock, however, differed from its predecessors. Though the loss of life was much greater, road and rail communications were not damaged, trees, lamp-posts and most of the telegraph poles remained standing, and electric current was available from the first hour of the shock. The great destruction in Quetta City is traced to the poor quality of the buildings, the erection of earthquake-proof houses having been generally neglected. In the areas of excessive damage, the few buildings that were earthquake-proof remained intact, and not even their chimneys fell.

Tercentenary of the Muséum National d'Histoire Naturelle

THE tercentenary of the Muséum National d'Histoire Naturelle in Paris has been celebrated during the past week, and included a *séance solennelle* on June 25 in the presence of the President of the Republic. Sir Arthur Hill, director of the Royal Botanic Gardens, Kew, was the principal delegate from Great Britain, and delivered an address in the name of the foreign delegates who were present. In view of the number of delegations attending the gathering, it was decided to select representative men of science to deliver addresses; Sir Arthur Hill spoke on behalf of the foreign delegates and also as a botanist,

M Lacroix, a geologist, represented the Institut de France, and M. Caullery, a zoologist, acted on behalf of the French delegates

Loss of the *Dana*

It is reported in *The Times* of June 24 that the Danish Government's scientific research ship *Dana* sank on June 23 in the North Sea, sixty miles west of Ringkjöbing, Jutland, after a collision with a German trawler. The director of the vessel's scientific work, Dr. Å. V. Tåning, and the crew were saved The *Dana* was well known to men of science and others through the work of the late Prof. Johannes Schmidt, director of the Physiological Department of the Carlsberg Laboratory, Copenhagen, on the migration of eels It may be remembered that the oceanographical expedition of the *Dana* in 1928–30 was described in an article by Prof Johannes Schmidt in NATURE of March 21, 1931, p 444 and March 28, p 487, which included a reproduction of a photograph of the *Dana*.

Floodlighting for the Royal Silver Jubilee

The floodlighting of London and of many provincial cities has generally been favourably received by the public. The use of coloured light for buildings like the London County Hall and Hampton Court Palace has been severely criticised. The latter development was partly due to the invention of gaseous electric lamps which provide an economical method of producing coloured lights In the *Illuminating Engineer* of June, P Good reviews the Royal Jubilee electric lighting He points out that the floodlighting of a building produces a visual impression which is quite unrelated to the daylight picture and should be so judged. If it has produced a satisfactory impression, it can be justified on artistic grounds. The Horse Guards Parade, illuminated by white light in 1931, was illuminated by violet light in 1935. Although one paper described it at the Jubilee as "a magic castle of palest violet", yet to most people it looked like a temporary structure of plaster and not worthy to be compared with its appearance on the earlier occasion when illuminated by white light. The electrical industry has shouldered the burden of the cost of providing permanent installations at Buckingham Palace, the Horse Guards Parade, the National Gallery and 'Big Ben'. Other interests are paying the cost of the permanent floodlighting of St. Paul's Cathedral. The floodlighting of public gardens has been universally praised. St. James's Park at night illuminated by 300 gas floodlights was a great attraction When the development of the buildings on the south side of the Thames is completed, it is to be hoped that arrangement will be made for floodlighting and that commercial advertisements will be excluded.

Electric Supply Tariffs in Great Britain

A serious hindrance to the rapid development of public electric supply in Great Britain is the great inequality in the charges made for electricity in many neighbouring districts. In a paper on public supply tariffs by J. A. Sumner read to the Institution of Electrical Engineers on February 28, it is concluded, after a careful study of methods of lowering the costs of distribution, that it is not unreasonable to forecast that electricity will be available within the next few years to all consumers at a rate of 0·5*d*. per unit Mr Sumner begins by comparing the costs per kilowatt of a private supply station with that of a public supply. Statistics for the case when Diesel engines are used for the private supply prove that it is the more expensive It appears that many undertakings are selling electricity for power purposes at a lower rate than is required to compete with the real costs of running private plant Hence in some cases the domestic consumer is penalised unfairly. It is pointed out that the distinction between 'urban' and 'rural' supply is sometimes unnecessary, as in many cases the capital expenditure for dwellings near the mains is much the same in the two cases. The analysis of the statistics proves that the merging of electricity areas into much larger single districts than at present is necessary for the reasonable standardisation of tariffs It is possible in this way to balance the inevitable deficit of a newly-developed area against the surplus from the older areas By this means a uniform tariff can be kept throughout each single large administrative district.

Applications of Photo-electric Control

The *G.E.C. Journal* (General Electric Company) of February gives an interesting review of electrical progress and development in 1934. Many useful devices are described. Aerodrome obstruction and boundary lights must be switched on when daylight is poor and when darkness approaches in the evening. It is essential that the pilots see the boundary of the aerodrome and any obstructions in the vicinity. The photo-cell has been successfully applied to the control of these lights. At Croydon Airport the switching on of the obstruction light is controlled by a photo-cell amplifier. Another useful application of photo-cells is to control the speed of escalators. The wear and tear of escalators like those in the underground railways of London which are in continuous use is extremely heavy; and renewals and repairs are expensive and, owing to the restricted space, are difficult to carry out. It is desirable to keep the speed low during slack periods at the less-frequented stations when no one is on the escalator. At the entrance to the stairway, a suitable lamp is installed to shine across the footway on to a photo-cell similarly mounted on the other side, just below the handrail. When this beam is interrupted by the entrance of a passenger, the stairway is speeded up in several stages so that the passenger feels no shock, and the escalator continues to run at a high speed until the passenger has time to reach the top. This is attained by a time delay device using a radio valve. If other passengers come on to the stairway before the last one reaches the top, the time delay device resets, so that the high speed continues until the last passenger gets to the top, after which the low speed comes into operation.

Early English Railways

IT is known that in the archives of various foreign countries there are documents of interest to students of the history of technology, but seldom is any of this material published. One such document, however, has recently formed the subject of a paper by Mr. P. Zabarinskiy published in vol 4 of the "Archives for the History of Science and Technology" The paper itself is in Russian, but with it is the letter of William Vaughan dated, London, June 14, 1804, and addressed to his Excellency Vice-Admiral Chichagoff, minister of the marine at St Petersburgh William Vaughan (1752–1850) was a director of the Royal Exchange Assurance Corporation, London, and was much interested in canals and railways and docks Railways, he said, were common in England and Wales for the conveyance of coals, limestone, ore and such things, and in the London Docks, in which he evidently was particularly interested, railroads and waggons were used in the excavations Experiments were apparently made at the Docks and in one of these, he said, "In six days of 12 hours, 25 men filled, 24 boys drove and 24 horses conveyed, 3650 cubic yards of earth to the distance of 400 yards and returned the waggons empty" Vaughan described clearly the turntables used on the banks of the Thames, gave estimates of the cost of removing material and made some remarks on the use of railways in Russia.

Work of the Rockefeller Foundation

THE Rockefeller Foundation's report for 1933 presents a tale of vast and varied activities, for the financing of which it had, in pursuance of its mission "to aid in the process of the rationalisation of life", made itself wholly or partially responsible Its policy in relation to the pressing social problems of the day is guided by the principle that it "can neither remain indifferent to them nor relinquish the support of the fundamentals on which in the long run the control of man's destiny depends". In medical and natural sciences, emphasis has been laid on the problem of mental health and the advancement of the rapidly evolving modern science of man, in the social sciences, on the problem of economic structure and process, international relations and community organisation and planning; and in the humanities, on the encouragement of international cultural understanding and the preservation and interpretation of American culture Early in the year a sum of a million and a half dollars was set aside for emergency grants for work in connexion with the 'new deal' programmes. Contributions were also made as an emergency measure towards the salaries of eminent scholars displaced for political reasons in Europe and 'adopted' by universities in Europe and the United States. Appropriations during the year totalled about ten million dollars. Among the larger appropriations in the field of the social sciences were: Brookings Institution for Economic Studies, 250,000 dollars; Institute of Economic and Social Research, Paris, 350,000 dollars; League of Nations, 275,000 dollars; National Bureau of Economic Research, New York, 225,000 dollars, social science research aids, 150,000 dollars, Social Science Research Council, New York City, 265,000 dollars.

Scientific Horticulture

THE third Year book of the Horticultural Education Association appears under the new title "Scientific Horticulture". It is longer than in previous years, its contents cover a wider field, and go far to justify the change of heading. The presidential address of the Association is by Dr T Wallace, and deals with "Science and Fruit-growing", mainly from a historical point of view. Many of the papers in the volume were delivered at a revision course in horticulture arranged by the University of Reading in September, 1934 The practical nature of the lectures of this course is at once apparent—they deal with the highest-grade modern processes in vegetable culture, glasshouse work and bulb-growing, together with descriptions of diseases and pests. They are incorporated as Bulletin 47 of the University of Reading Articles contributed specially for the year-book include "Commercial Horticulture in Northern Ireland" by W. J. Megaw and E. E Skillman, "Fruit-tree Spraying Equipment" by J Turnbull, "The R.H.S. Apple and Pear Conference, 1934" by N. B. Bagenal and R T. Pearl, "Selection of Soils for Dessert Apple Growing" by B. S Furneaux, "Twenty-one Years' Fruit Research at East Malling" by R T. Pearl and R. Hart", "Waste Products in Horticulture, their Utilisation as Humus" by Sir Alfred Howard, and "Research at Rothamsted of Importance in Horticulture" by Miss M. D. Glynne and H V. Garner. The volume entirely justifies its name, and is a great credit to Mr R T Pearl, its honorary editor One has the feeling, however, that the bias is on the practical side, and that the newer scientific principles which most gardeners have yet to learn—such as photoperiod, seed stratification and control, plant sterility and the conditions affecting vegetative regeneration—are not expounded. The school garden, the primary stage in horticultural education, receives no notice whatever.

Over-population in America's Deer Herds

IN the Yellowstone National Park, the two great herds of wapati or 'elk' now comprise about 30,000 individuals, and in the northern area the drought-reduced pastures have accentuated a long-standing problem of over-population (Science Service, Washington, D C.). The fundamental cause of the food scarcity which has resulted is the inevitable restriction of the natural emigrations of the herds, for outside the northern boundary of the Park, the Yellowstone Valley is occupied by cattle ranches These make an impassable barrier and confine the deer permanently to a quite inadequate portion of what is naturally only their winter range. Over-grazing has altered the vegetation for the worse, most of the nutritious native grasses have been killed out, and their place taken by a weed grass, fox-tail, which apart from its low nutritive value, pierces the gums and permits the growth of a fungus

producing the disease of 'lump-jaw'. Two solutions have been proposed: one that about half the total number of deer should be captured, transferred to a central slaughtering station outside the Park, and killed and distributed to destitute Indians, the other that the captured animals should be set free in areas of Montana where they could be hunted by sportsmen. The second plan is that favoured by National Park officers, but they insist that whatever plan is adopted, it must be carried out promptly, because of the daily increasing seriousness of the emergency.

Meteorology in India

THE report on the administration of the Meteorological Department of the Government of India in 1933–34 has for frontispiece a very good photograph of a tornado which visited Peshawar on April 5, 1933, probably the first photograph to be obtained of this phenomenon in India. The Department has again been hampered by the heavy curtailment of expenditure initiated in 1932, and has nevertheless had to face increased demands for meteorological information on the part of air mail services. It was necessary, therefore, simply to dispense with additional forecasting centres and other facilities demanded by the circumstances, and to carry on with what is described as a skeletal meteorological organisation along each air route. Between April 1, 1933 and March 31, 1934, nearly six thousand weather reports and forecasts were issued to aviators by the departmental forecasting centres at Karachi, Calcutta and Poona and the Royal Air Force centres at Quetta and Peshawar, which are under the technical though not the administrative control of the Department. The report quotes remarks made in a discussion at the Royal Geographical Society of an account of the Ruttledge Mount Everest Expedition that are a strong tribute to the help that can be given to mountain expeditions by local forecasting centres in India. In this case, the Expedition was in touch with Dr. Sen of the Calcutta office for the supply of special forecasts. Scepticism of the value of forecasts that are based largely on observing stations at a comparatively low level was quickly seen to be unjustified, particularly when an abnormally early monsoon was successfully predicted. Among the many activities of the Department, it may be noted that the recently established branch of agricultural meteorology carried on special researches into matters affecting the growth of crops, and that some of the results have already been published.

The Engineer as Planner

IN an article entitled "The Engineer as Planner" reprinted by *Engineering Inspection* of January 1935, Dr. Victor Cofman emphasises the fact that the important factor in the solution of economic and social problems is the application of the spirit and methods of engineering and science to the wider field of human relations, not the particular person who does it. While everyone agrees that the planning of production is the obvious duty of the engineer, opinions are divided as to how far the engineer can help in the social and economic fields, and it is often pointed out that eminent engineers and men of science do not show particular perspicacity or vision when dealing with social problems It is essential that those who will have to consider social questions must have a full knowledge of the pertinent facts, and it may be necessary under existing conditions to have a team consisting of sociologists and economists, practical men acquainted with the problems, working together with engineers and men of science acquainted with the methods of science The opponents of planning take it for granted that planning is synonymous with greater restriction upon individual freedom, but one may plan for freedom and peace just as one may plan for oppression and war. The true opposition is not between planning and liberty, but between arbitrary interference and liberty.

Bibliography of Seismology

THE last quarterly number of this useful work, which is edited by Mr. E A. Hodgson and published by the Dominion Observatory, Ottawa, completes the twelfth volume and the list of memoirs for 1934. The total number of memoirs referred to during the year is 506, some of them in title only, but many of the more important accompanied by a brief abstract It is satisfactory to notice that the number of collaborators is increasing, and that new countries are being added to the list, though there is still no representative for Great Britain. The subject-index for the year under more than fifty headings adds greatly to the value of the Bibliography.

The Planetarium

ACCORDING to an article in *The Times* of June 22, accommodation for a planetarium is being included in the plans for rebuilding the centre portion of the Science Museum, South Kensington. It is stated that Germany already has thirteen planetaria, America four, Italy two and Holland, Sweden, Austria and the U.S.S.R. one each. Such an instrument enables celestial bodies to be shown as bright objects on the inside of a large darkened dome, and by means of elaborate mechanism their movements can be demonstrated. The method thus marks a great advance on the orrery, in which the positions and movements of bodies in the solar system are represented in a mechanical model. It will be recalled that the first Zeiss planetarium, erected at Munich, was described and illustrated in NATURE of December 27, 1924, p. 937.

Astronomical Phenomena during July

VENUS is a conspicuous object in the evening sky. The planet reaches its greatest eastern elongation on June 30, when the stellar magnitude is $-4 \cdot 0^m$, but the planet will continue to increase in brilliance throughout July, the stellar magnitude being $-4 \cdot 2^m$ on July 31. As both Mars and Jupiter are conspicuous in the evening sky, one can get a very good idea of the ecliptic stretching across the sky, especially

when the moon is visible Mars, the magnitude of which is $+0\cdot3^m$ at the beginning of July, will decline in brightness by three tenths of a magnitude during the month The planet will move towards Jupiter, which is near α Libræ Jupiter's magnitudes are $-1\cdot9^m$ and $-1\cdot7^m$ at the beginning and end of the month respectively. Saturn's Right Ascension is 22^h49^m, about eight hours behind Jupiter and 11^h36^m behind Venus at the end of the month Saturn's declination being 9° S, it will not be possible to see these four of the five naked eye planets in the same sky from stations north of terrestrial latitude 40° N. during July. Venus is in conjunction with Neptune on July 25 at 06^h G.M.T., Venus being 2·6° S. There is a partial eclipse of the sun, partly visible at Greenwich, on June 30 The eclipse begins at 20^h07^m G M T. and fourteen per cent of the disc will be covered at sunset A total eclipse of the moon on July 16 is also partly visible at Greenwich. The moon enters the penumbra on July 16 at 02^h15^m and leaves the penumbra on July 16 at 07^h43^m, the eclipse being visible on the Atlantic Ocean generally A further partial eclipse of the sun takes place on July 30; this will be invisible at Greenwich.

Announcements

THE medal of the Society of Chemical Industry has been awarded to Dr. E. F Armstrong, "for conspicuous services to chemistry". The presentation will be made during the annual meeting and conference of the Society in Glasgow on July 1–6, and Dr. Armstrong will deliver his medallist address on Thursday, July 4, on "The Past, the Present and the Future". Previous recipients of the Society's medal, which is one of the highest awards in the chemical industry, include many well-known men whose work forms the basis of modern science. Notable amongst these are the names of Mr. C. F. Cross, a pioneer of the artificial silk industry, Sir James Dewar, Sir Henry Roscoe, Sir William Crookes, Sir Joseph Swan, Dr. Ludwig Mond, Sir W. H. Perkin, and Mr. John Glover, who was the first to receive the award.

MR. WALTER ELLIOT, Minister for Agriculture and Fisheries, has been elected a fellow of the Royal Society under the special statute which permits the election of "persons who have rendered conspicuous service to the cause of Science, or are such that their election would be of signal benefit to the Society".

MIRZA MUHAMMAD KHAN QAZVINI, a distinguished Iranian savant, has been elected an honorary member of the Royal Asiatic Society in recognition of his many valuable contributions to the cultural history of his country.

THE annual general meeting of the Dechema (Deutsche Gesellschaft für chemisches Apparatewesen E.V.) will be held on July 3–5 at Koenigsberg, together with the general meeting of the Verein Deutscher Chemiker. The general topic of the meeting will be "German Materials in Chemical Engineering".

UNDER the auspices of the Royal Society for the Protection of Birds, the University of London Animal Welfare Society, and the Society for the Preservation of the Fauna of the Empire, an evening meeting will be held at the Royal Geographical Society, Kensington Gore, London, S W.7, on July 2 at 8.30, when Capt C. W R. Knight will exhibit his new film of South African animals, entitled, "African Adventure" The chair will be taken by the Right Hon the Earl of Athlone Admission will be by invitation only, and applications should be made to the R.S P B, 82, Victoria Street, London, S W 1.

THE public health services in Mexico are being reorganised as follows: inspectors of food, water, drainage, epidemics, immigrants and prostitutes are being appointed, co-operative medico-sanitary units are being formed, a sanitary unit has been created in the department of irrigation, and sanitary brigades are being organised for carrying out vaccination against small-pox and typhoid fever

A FRENCH Medical Aeronautic Association has recently been founded in Paris under the presidency of M Emile Strohl It will form a centre for technical and medical documentation, enabling medical men to collect physiological and pathological data connected with aeronautics and flight at high altitudes It will also facilitate more direct relations between medical men and engineers and technicians for the elaboration of plans concerned with the hygiene of passengers and the transport of the sick and wounded Further information can be obtained from the general secretary, M. Robert Charlet, 95 rue Jouffroy, Paris, 17e.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A tutor in mathematics in Westminster Training College, Horseferry Road, London, S.W 1—The Principal (July 4) A resident lecturer in geography in the Saltley Training College for Schoolmasters, Birmingham—The Principal (July 5). An assistant teacher in the Mechanical and Marine Engineering Department of the Liverpool City Technical College—The Director of Education, 14, Sir Thomas Street, Liverpool, 1 (July 5). An assistant lecturer in mechanical engineering in the Manchester Municipal College of Technology—The Registrar (July 9) An assistant in botany in the University of Aberdeen—The Secretary (July 12). A lecturer in pharmacology in the University of Sheffield—The Registrar (July 12). A resident tutor in geography in Borough Road College, Isleworth, Middlesex—The Principal (July 17). A demonstrator in physics in the University of Leeds—The Registrar (July 22) A lecturer in electrical engineering in the Royal Technical College, Salford—The Director of Education, Education Office, Salford. Research assistants to the British Cotton Industry Research Association—The Director, Shirley Institute, Didsbury, Manchester. An assistant lecturer in agricultural biology in Seale-Hayne Agricultural College, Newton Abbot, Devon—The Secretary.

Letters to the Editor

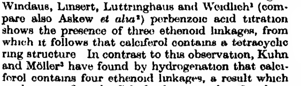
The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 1078.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

Ring Structure of Calciferol

ALTHOUGH calciferol has been shown to be isomeric with ergosterol ($C_{28}H_{44}O$), comparatively little information has hitherto been adduced concerning the detailed structure of this vitamin. According to Windaus, Linsert, Luttringhaus and Weidlich[1] (compare also Askew *et alia*[2]) perbenzoic acid titration shows the presence of three ethenoid linkages, from which it follows that calciferol contains a tetracyclic ring structure. In contrast to this observation, Kuhn and Möller[3] have found by hydrogenation that calciferol contains four ethenoid linkages, a result which we have confirmed. Calciferol cannot therefore be a tetracyclic compound. Further evidence in support of this view arises from the work of Lettré[4], who on dehydrogenation of calciferol failed to obtain Diel's hydrocarbon ($C_{18}H_{16}$). Again, this author has demonstrated that tachysterol, which is a direct intermediate in the photochemical conversion of ergosterol into calciferol, is also tricyclic, probably having the constitution I or II.



I II III

During the past year, we have been studying the oxidative degradation of both calciferol and calciferyl acetate, and have found that, with either chromic anhydride or potassium permanganate, an oily aldehyde is obtained, characterised by its well crystalline semicarbazone, m.p. 242°. Analysis of the latter shows that the aldehyde has the formula $C_{21}H_{34}O$, from which it follows that the disrupted fragment must include the hydroxylated ring *A*, which consequently cannot be fused to the remainder of the cyclic system as in ergosterol.

Our analytical data for the semicarbazone appear to preclude the formula $C_{21}H_{32}O$ for the aldehyde, indicating that one of the ethenoid linkages of calciferol is present in ring *A*. On this evidence, formula III is suggested for the vitamin, the formation of the aldehyde $C_{21}H_{34}O$ occurring by simple rupture of the $\Delta^{5:6}$ ethylene linkage. It must be observed that the location of the ethylene linkages at $\Delta^{1:10}$ and $\Delta^{8:9}$ is provisional and remains to be confirmed.

Colorimetric Estimation of Œstrin in the Urine of Non-Pregnant Women

LAST year we reported the details of a method by which it is possible to determine the œstrone and œstriol content of human pregnancy urine colorimetrically with a reasonable degree of accuracy[1]. Since the publication of our paper we have received numerous inquiries as to whether the method can be used for the determination of the œstrin content of urine of non-pregnant women. As this question seems to be one of some general interest, and since in our paper we made no mention of the possibility of using our method for this purpose, we wish to take this opportunity of mentioning briefly our views on the matter.

We have made numerous attempts to estimate the œstrone and œstriol in the urine of non-pregnant women by our colorimetric method, but so far the results have been far from encouraging. Owing to the relatively small amounts of œstrin present it is necessary to carry out the colour reaction in a much larger quantity of extract than we use in the case of pregnancy urines, and hence the colour reaction is carried out in fractions which contain a relatively much higher proportion of non-œstrogenic phenolic substances. The final colour obtained in such tests is a dirty brown instead of a clear pink as is obtained with pregnancy urine extracts. This colour can, of course, be analysed with the Lovibond tintometer, but we do not feel at all confident that the red component of the brown colour can be accepted as a true measure of the œstrin present.

We feel, therefore, that our method as described for pregnancy urine is of little value for the estimation of the much smaller amounts of œstrin present in the urine of non-pregnant women, and we cannot advise its use for this purpose.

Radio-Transmission of Cosmic Ray Data from the Stratosphere

ON April 1, 1935, an apparatus recording cosmic rays by the coincidence method and transmitting the signals by Moltchanoff's radio method, ascended to the stratosphere from the Institute of Aerology at Slootsk (25 km. from Leningrad). The construction of the apparatus and observations with it obtained in an aeroplane flight have already been described[1].

The coincidences were recorded by a relay, which switched on the anode circuit of the radio-oscillator. The radio-signals made in this way were received and counted at the earth's surface by three observers.

Besides the coincidences, the apparatus transmitted at more or less regular intervals the total

number of discharges produced in one of the two counters. For this purpose, switchings were effected in the amplifier by means of a barograph about every 5 minutes. The number of switchings indicated the pressure data.

The apparatus functioned for 58 minutes. Judging by the data of the three observers—which were in fairly good accord—the number of the coincidences produced by the vertical beam of cosmic rays increased with the increase in altitude as follows: up to the altitude of 5 km. by 9 times; up to 7 km. by 18 times; up to 9 km. by 27 times. At greater heights the number of coincidences ceased to increase and the last observation, obtained at the altitude of 12·2 km., even showed a slight fall.

The number of discharges produced in one counter increased up to the altitude of 6 km. by 3·5 times; up to 7·5 km. by 6 times. At greater altitudes (up to 13·6 km.) the number of discharges became too great to be counted, but the intervals were used for tuning the receiver.

The apparatus ceased to function at the altitude of 13·6 km. as soon as the balloons started descending after one of them had burst.

It seems that the method described may be used for the study of cosmic rays at great altitudes, especially in thinly populated localities (near the equator and in the arctic region), where finding self-recording apparatus would present considerable difficulty.

In conclusion, I wish to express my sincere thanks to Prof. P. Moltchanoff for his continued interest, his many helpful suggestions and for the organisation of the flight.

The Phosphorescence Process as Revealed by the Luminescence from Solid Nitrogen

SOME years ago it was found by me that a number of bands appearing in the afterglow of solidified nitrogen were due to forbidden transitions from metastable, molecular electronic states.

The appearance of bands from forbidden transitions in the crystalline state was explained by the fact that they only appear in the α-form of nitrogen where the molecular axes are fixed in the lattice, while they are absent in the β-form where the molecules rotate[1].

This result would suggest that the rate of decay of the afterglow was determined by the probability for the occurrence of the forbidden transition. This view, however, could not be upheld because the rate of decay sometimes is very slow and does not follow an exponential law.

In order to explain the phosphorescent property (afterglow) of nitrogen, it was assumed[1] that the bombarding rays produced a dissociation of the molecules into atoms which might be neutral or ionised.

Energies corresponding to the elementary process of the chemical reaction were transferred to the molecules in such a way that they were brought into an excited state with electrons raised to higher levels. In this way the phosphorescence appears to be closely related to chemi-luminescence. The difference is mainly that in the case of phosphorescence the reacting substances have first to be produced by means of radiating quanta.

This view has recently obtained an interesting confirmation by the study of the ε-system (Vegard-bands) from solid nitrogen, which some years ago was shown by me to result from the forbidden electronic transition from the $A(^3\Sigma)$ level to the normal state $X(^1\Sigma)$ of the nitrogen molecule.

For the upper state A (bottom state of the first positive group) we know at least 15 vibrational levels. For the ε-system no bands are known starting from a vibrational level (A) with quantum numbers n' greater than 7. A few bands were observed for $n' = 7$, and for all values of n' equal to or smaller than 6 a large number of bands were observed.

This sudden break in the vibrational states of the upper ε-level was first explained by means of the potential curves for the upper and lower state and by a reasoning similar to that underlying the Franck-Condon theory of intensity distribution of vibrational bands.

Recently, more accurate determinations of the potential functions have shown that this explanation can scarcely be maintained. The abrupt limit of the upper vibrational states, however, can be accounted for, if we assume that the ε system—which also remains in the afterglow—is excited through recombination of normal nitrogen atoms formed during the ray-bombardment.

The dissociation energy of nitrogen has been determined by Herzberg and Sponer[2], and recently the value $D(N_2) = 7{\cdot}345$ volts was given by Büttenbender and Herzberg[3].

The energy necessary to excite the vibrational states $n' = 7$ and $n' = 8$ of the A-level is 7·29 and 7·45 volts respectively. The dissociation energy $D(N_2)$ is just sufficient to excite the $n' = 7$ state, but too small to excite the level $n' = 8$.

The assumption that the ε-system afterglow is due to a recombination of nitrogen atoms (chemical reaction) thus accounts for the fact that ε-bands occur for $n' = 7$, but not for n' larger than 7.

The Solution, by the Method of Association, of Problems in Inverse Probability

IN his review[1] of a book by Sir Arthur Eddington, Prof. Dingle criticises Sir Arthur's solution of a certain problem in inverse probability. Prof. Dingle proposes a second, simpler, and analogous, although different, problem: If A and D each speak the truth once in three times independently, and A says that D lies, what is the probability that D speaks the truth? He argues that from our knowledge of D, the probability is 1/3, while from our knowledge of A it is 2/3, and hence that neither for his problem nor for Eddington's can there be any consistent, correct solution. Yet Prof. Dingle's problem can be regarded

as a problem in statistical association, and admits of one, and only one, solution.

Consider the universe of N events, each consisting of D's either lying or telling the truth, and of A's either affirming or denying that D has lied. By the data, the frequency of D's lying must be $2N/3$, and of his telling the truth, $N/3$. Also by the data, the frequency of D's lying followed by A's statement that D has lied must be $2N/3$ times $1/3$, and followed by A's denial that D has lied it must be $2N/3$ times $2/3$. Likewise, the frequency of D's telling the truth followed by A's affirming that D lies must be $2N/9$, and followed by A's denying that D has lied it must be $N/9$. The accompanying association table exhibits these frequencies; there are no inconsistencies. Out of the sub-universe $4N/9$ in which A says that D lies, D actually lies $2N/9$ times and tells the truth $2N/9$ times, and hence the desired probability is $1/2$. It can be nothing else.

	A says that *D* lies	*A* denies that *D* lies	Total
D lies	$2N/9$	$4N/9$	$2N/3$
D tells the truth	$2N/9$	$N/9$	$N/3$
Total	$4N/9$	$5N/9$	N

Whenever the prior probabilities, as here, are known, any straightforward problem in inverse probability can be recast into the form of an association or contingency table, and must lead to a unique solution. But when one tries to cast into the form of a table of association or contingency a problem in inverse probability for which the prior probabilities are unknown, then the ratios between the total frequencies of the 'cause' rows remain capable of arbitrary adjustment, and no unique probability can in general be found for a particular cause of the observed event. It is only when one or more of the class frequencies vanish in the table that any conclusions can be drawn without a knowledge of the prior probabilities, the argument then becoming a conditional syllogism, *modus tollens*. The method of association not only clarifies the solvable problems in inverse probability, but also demonstrates the logical fallacy involved in almost all applications of the method of inverse probability, when the prior probabilities are unknown.

T. E. STERNE.

Harvard College Observatory,
Cambridge, Mass.
May 4.

[1] NATURE, 135, 451, March 23, 1935.

DR. STERNE's statement concerning me, that: "He argues that . . . neither for his problem nor for Eddington's can there be any consistent, correct solution", is not quite accurate. I did not dispute that a combination of the data was possible which would allow of a unique result, but I claimed that such a combination did not yield 'probability' according to any significant meaning of the word. If the square of a man's height be divided by the natural logarithm of his age, and the result called his 'affability', this quality can be uniquely determined, but it gives no indication of the reception he is likely to give us. We can either (*a*) define probability in a purely mathematical way and so obtain a unique solution which may be both consistent and correct (although, in my opinion, Sir Arthur Eddington's solution was neither); or (*b*) refrain from calling meaningless mathematical functions 'probability', and then obtain two solutions to each problem.

I am willing to discuss the correctness of Sir Arthur Eddington's solution or the significance of his implied definition of probability, but to avoid taking up space unnecessarily, I will wait to hear in which, if either, question Dr. Sterne is now interested.

HERBERT DINGLE.

The Breeding Age of the Yellow-bellied Toad, *Bombina variegata variegata*, Linn.

IN view of the scarcity of data on the age at which *Salientia* begin to breed, and an apparently entire lack of information for the above species, it may be of interest to record that I have to-day seen eggs laid by a pair of these toads which were hatched in my terrarium in 1932. The animals are not yet full-grown, the male measuring 35 mm., the female 37 mm., whilst full-grown toads are about 45 mm.

The males had well-developed nuptial pads last summer, and vigorously attempted to mate with females of all ages, but were prevented from securing adult females permanently by the pugnacity of the older males[1]. While I was watching last year, young females always released themselves.

The first sign of sexual behaviour was seen as early as 1933, when an animal only 20 mm. long seized another even smaller, which responded by the typical female release reaction. Behaviour which is sexual in character is not in this species invariably associated with reproduction, as noted for *Bufo bufo* by Hinsche[2], but it is interesting to find this complex behaviour already in existence in very small toads only one year old.

Fossils as Indicators of Continental Drift

MOST geologists will doubtless agree with Sir Arthur Smith Woodward as to the need for caution in the interpretation of some of the fossil evidence which has been regarded as supporting the hypothesis of continental drift[1]. The possibility that fossils referred to the same genus or even the same species may have been developed in different areas (whether from a common or different ancestors) is familiar to those who have been concerned with Mollusca or Brachiopoda, but the implications as regards classification or the value of fossil lists are not so well understood, and Sir Arthur's warning is no doubt timely.

It may be remarked, however, that where, in any system, numbers of similar forms occur in a comparable sequence in widely separated areas, the evidence of a former connexion between the areas is immeasurably stronger; especially is this true where there is a succession of unrelated species belonging to different groups.

These conditions appear to be suitably illustrated in the Upper Carboniferous rocks of western Europe and the eastern States of America, where there is the additional advantage that both flora and non-marine fauna have required practically continuous continental areas for their migrations. As regards the floral succession, in particular, the similarity of the

sequences in the two continents has recently been emphasised by Profs. Jongmans and Gothan[2]. Many European species belonging to all the more important Carboniferous genera occur in Pennsylvania, West Virginia and Kansas in substantially the same sequence as that found in Europe, so close is the agreement that a fairly detailed correlation is proposed

It may be possible to account for these facts by hypotheses other than that of continental drift, but I would suggest that they are of real importance in any discussion of the problem

A E TRUEMAN

Geology Department,
University of Bristol
June 3

[1] NATURE, 135, 900, June 1, 1935
[2] W. J Jongmans und W Gothan, "Florenfolge und vergleichende Stratigraphie des Karbons der Östlichen Staaten Nord-Amerika's. Vergleich mit West-Europa" Geol Bureau Heerlen, Jaarverslag over 1933, pp 17–44, 1934

PROF. TRUEMAN, who has specially studied Carboniferous stratigraphy, makes an important addition to my brief article. Following Wegener, I merely mentioned that the theory of continental drift might explain the observed distribution of Carboniferous land and fresh-water life in the northern hemisphere Prof Trueman rightly emphasises the significance of the identity of succession of this life in widely separated areas. There can, indeed, be no doubt that identity in succession of whole faunas and floras in two distant regions is much more satisfactory proof of former connexion than the apparent identity of single groups to which I chiefly referred.

A. SMITH WOODWARD.

Statistical Aspect of the Production of Primary Lesions by Plant Viruses

MR BALD points out in NATURE of June 15 (p. 996) that an attempt to fit the equation $y = N(1 - e^{-ax})$ to data obtained by Samuel and Bald[1] meets with poor success, especially at high dilutions. Samuel and Bald plotted the logarithms of their counts against the logarithms of the dilutions and found that at high dilutions the points lay on a straight line with a slope of 0·6 It may be easily shown that the equation predicts a slope of unity Data published recently by Price[2], Chester[3], Caldwell[4] and Beale[5], give experimental curves with approximately unit slope. This suggests that the discrepancies between Samuel and Bald's experimental counts and values calculated from the equation may in a large part be due to the fact that their data are at variance with other measurements in the literature.

It is true that the equation gives low values at high dilutions, and this was pointed out and a possible explanation offered. It is also true that in this range more plants have to be used to obtain accurate results, since the error is a function of the total number of lesions. The use of log paper for plotting results exaggerates the weight of measurements at high dilutions.

Finally, the sixteen dilution curves fitted to this equation give no indication that its application, at least over a considerable range of dilution, is limited to highly purified virus preparations. Contrary to the idea that only certain cases were chosen, an attempt was made to include all published dilution curves giving data at high enough concentrations to establish the nature of the curve The lack of concordance between the dilution data reproduced in Mr Bald's letter and the curves obtained by other workers indicates that Samuel and Bald's data cannot be used to condemn the validity of the equation.

Coagulation of the Blood as a Chain-Reaction

IN studies on the mechanism of the coagulation of blood, I have found that an active principle of coagulation is formed in the process of coagulation—a principle which can be transferred indefinitely into new plasma without decrease in its activity In one experiment, 30 γ of an active phosphatide[1] was added to a certain amount of chick plasma. About one minute before coagulation took place, another similar portion of plasma was 'inoculated' with 0 03 c c of the first plasma, which was still liquid Before coagulation of the second plasma took place a third portion of plasma was inoculated, then the coagulation time of the second plasma was recorded Then a fourth portion of plasma was inoculated from the third, and the coagulation time of the third plasma was recorded Inoculation of a series of plasmas was continued in this way successively until the original amount of active phosphatide added was diluted to 5×10^{-16} γ, and the experiment was discontinued The clotting time was practically constant through all the passages

Further experiments showed that the coagulation-active substance formed during the clotting process of blood plasma increases and disappears almost instantaneously at the very moment of coagulation The formation of the active principle in the plasma occurs shortly after the 'inoculation' rather slowly, but it increases very rapidly until it reaches an explosion-like rate just before the plasma clots As soon as the coagulation has taken place, the activity of the principle disappears almost completely The curve plotted for the formation of active substance during the coagulation process has an exponential form

A theory of blood coagulation as a chain-reaction finds support in our experimental facts It is still an open question, on which work is proceeding, whether free radicals are produced during this process. As in chain reactions, we have here an initial reaction and a chain interrupting reaction. The latter is indicated by the sudden decrease in activity when the substrate is used up. In our case the chain reaction velocity is exponential, and should belong to such a type as foreseen by Christiansen and Kramers[2] and proved experimentally by Hinshelwood and Grant[3] for the hydrogen-oxygen system In this kind of chain-reaction more than one active molecule or free radical of the kind which started the reaction may be set free by any of the elementary reactions.

Oscillations of Hollow Quartz Cylinders

WITH reference to the letter by Ny Tsi-Zé and Tsien Ling-Chao published in NATURE of August 11, 1934 (p. 214), it is interesting to note that annular quartz rings cut in a plane perpendicular to the optic axis were investigated by Giebe and Scheibe[1] in 1928, by the luminous resonator method. Such a ring, oscillating in its fundamental longitudinal mode, was also made by Dye, and was afterwards developed to form the primary standard of frequency at the National Physical Laboratory. More recently, similar rings oscillating in an overtone longitudinal mode have been investigated in an attempt to incorporate the most successful features of the different types of quartz oscillators which have been developed to form frequency standards in this and other countries

In the type of ring oscillator now being investigated, the exciting electrodes consist of two brass cylinders around the inner and outer edges of the ring. An overtone circumferential mode of vibration having six nodes is employed. The ring may be mounted rigidly at the nodal points so that movements within the electrodes are completely eliminated By adjustment of the width of the ring, that is, the difference between its internal and external radii, it has been found possible to reduce the temperature coefficient of frequency over a limited range to a few parts in a hundred million, which is a hundred times smaller than the usual coefficient for longitudinal vibrations of quartz The temperature at which the low coefficient is obtained can be adjusted to any desired value

Plasticity of Crystals of Sylvine

ATTENTION has frequently been directed to the plasticity of crystals of rocksalt when immersed in water. Some see the cause of the plasticity in the removal of surface layers with their cracks and defects Others suppose that water penetrates the crystal lattice and acts as a lubricant. It is interesting to observe the behaviour of crystals in a state of recent formation from solution or melt For this purpose I have made some experiments with sylvine(KCl).

I find that crystals of sylvine which, like those of rocksalt, are brittle under normal conditions, become plastic after treatment with water At high temperatures (700°–780°) sylvine possesses noticeable plasticity: it is deformed by small loads. The mobility of deformation may be adopted for calculation of the viscosity of the crystals, although variable in its value.

Crystals taken out of the solution in which they are grown and wiped with filter paper are very plastic at first. If exposed to the air without any special drying they become fragile in a few hours.

Sylvine crystallises in the form of parallelepipeds, sheets and fibres; sometimes also in skeleton forms. Sheets of 0·1 mm. thickness are so plastic that they can be bent so as to form tubes. Fibres 0·2–0·3 mm. in thickness and up to 10 cm. in length bend under their own weight.

Consequently sylvine crystals on forming either from melt or from solution possess considerable plasticity, and must yield easily to mechanical stresses This may explain the frequent occurrence of bent and twisted crystals

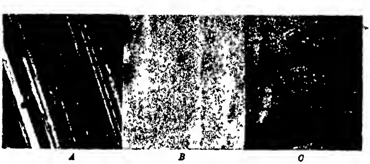
Electrolytic Method for obtaining Bright Copper Surfaces

IT is possible to polish a copper surface electrolytically by making it the anode in an aqueous solution of orthophosphoric acid at high current density (minimum 25 amp./dm.²). This mode of polishing is particularly suitable for metallographic



A B C

FIG. 1 ×400

examinations, and has been used for the examination of copper deposits in presence of various colloids.

The specimen is first roughly treated with emery paper, then cleaned cathodically in an alkaline solution and finally inserted for about two or three minutes in an aqueous solution of orthophosphoric acid, 50 per cent by volume of the commercial product, specific gravity 1·71. The current density was maintained at 60 amp./dm.² of the total surface The solution had to be cooled to avoid considerable increase of temperature. Any metallic plate will serve as cathode. Gas being vigorously evolved, a rotating anode helps to get a uniform effect. The microscopic analysis of the surface shows the lines produced by emery polishing (Fig. 1, *A*) to vanish completely (Fig. 1, *B*) and an attack by means of the usual agents gives the image reproduced on Fig 1, *C*. Should this attack be insufficient, the anodic polishing can be repeated for about thirty seconds to obtain a fresh surface ready for another attack. This method is much more rapid and more economical than polishing by alumina.

Twinning in Alpha Iron

IN a letter to NATURE of June 1, A. B. Greninger reports having observed twinning in alpha iron. Slow cooling through the A_3 temperature produced twins of the banded type, whilst deformation and recrystallisation resulted in twins which were seldom

banded. It was shown by me in 1928[1] that certain strained and annealed alpha iron crystals contained twins lying along (112) planes, and furthermore I cited evidence suggesting that twinning in alpha iron might sometimes be associated with twinned gamma iron from which it had cooled. It has also been observed[2,3] that on annealing a deformed single crystal of alpha iron the polygonal aggregate obtained gives pressure figures indicating uniform orientation, and it seems likely that this may also be associated with twinning.

The general importance of annealing twins to the metallurgist has hitherto been the evidence which they afford of the previous history (cold-working and annealing) of the specimen Unfortunately only X-ray methods can be relied upon to detect them with certainty in alpha iron, and now apparently some method of distinguishing between the two processes of origin is required

An interesting practical point may be connected with this twinning behaviour. Mild steel tinplate is said to be more ductile and to have better Erichsen values when cold-rolled and annealed than when hot-rolled and normalised. The former process probably produces a more highly twinned structure, which for crystallographic reasons would tend to deform more easily.

Dissociation Energy of the CO Molecule and the Sublimation Heat of Carbon

THE direct experimental values of the sublimation heat L of carbon obtained by several authors[1] lie between 139 and 177 kcal An accurate value can be deduced from the energy of dissociation D_{CO} of CO *into normal atoms*, since the well-known relations (at 0°K.):

$$
\begin{aligned}
C_{diam.} + \tfrac{1}{2}O_2 &= CO + 27{\cdot}6 \text{ kcal.} \\
CO &= C(^3P) + O(^3P) - D_{CO} \\
C(^3P)_{gas} &= C_{diam} + L \\
O(^3P) &= \tfrac{1}{2}O_2 + 58{\cdot}7 \text{ kcal}
\end{aligned}
$$

lead to

$$L = D_{CO} - 86{\cdot}3 \pm 0{\cdot}2 \text{ kcal. } (86{\cdot}3 \text{ kcal.} = 3{\cdot}74 \text{ v.e.}) \quad (1)$$

The value of D_{CO} was hitherto not exactly known. However, the predissociation in the $CO(B^1\Sigma)$ level[2] gives the upper limit: $D_{CO} \leqslant 11{\cdot}07$ v e. We obtain the lower limit in the following way: for the upper level $(A^1\Pi)$ of the fourth positive CO bands, which lies 7·99 v.e. above the ground $(X^1\Sigma)$ state, 16 vibration levels (2·41 v.e.) are observed, corresponding to $7{\cdot}99 + 2{\cdot}41 = 10{\cdot}40$ v.e. above the $(X^1\Sigma)$ state. This value is a lower limit for D_{CO}, if $CO(A^1\Pi)$ dissociates into normal atoms. By linear extrapolation (which gives in many cases values which are too high) of vibration levels of the $(A^1\Pi)$ state we obtain about 4 v.e. ($v'_{max.} = 43$), that is 12 v.e. above the $(X^1\Sigma)$ state The $(A^1\Pi)$ state could be formed only from atoms of equal multiplicity: (*a*) $C(^3P) + O(^3P)$ or (*b*) $C(^1D) + O(^1D)$ or (*c*) $C(^1S) + O(^1D)$, etc. Already the interpretation (*b*) leads to $D_{CO} \leqslant 8{\cdot}79$ v.e. $= 12 - 3{\cdot}21$ v.e. (3·21 v.e. being the sum of excitation energies of $C(^1D)$ and $O(^1D)$). According to (1), then $L \leqslant 5{\cdot}05$ v.e. (116 kcal.); this value must be excluded as being beyond the errors of determinations of L (it seems also too near to $L = 113$ kcal. for Fo) Consequently, we must assume that $CO(A^1\Pi)$ dissociates into non-excited atoms (if it is really a singlet state) and D_{CO} lies between 10·4 v e and 11·07 v.e D_{CO} is certainly much nearer to the upper limit, since at the 16th vibration level the convergence is still not sufficiently advanced. $D_{CO} = 11$ v e $= 253$ 6 kcal is probably not in error by more than 0 1 v e. Therefore we obtain $L = 7$ 26 v e $= 167$ kcal The restriction of the error limits to 0 1 v c. = 2 3 kcal eliminates one of the most important uncertainties inherent at calculations of formation energies of carbon compounds[3].

[2] D Coster and F Brons, *Physica*, 1, 155 1, 634, 1934 D N Read, *Phys Rev*, 45, 752, 1934 R Schmid and L Gerö, *Z Phys*, 96, 656, 1935
[3] L. Pauling and J Sherman, *J Chem Phys*, 1, 606, 1933 C T. Zahn, *J Chem Phys*, 2, 671, 1934 W Lasareff, *J Phys Chem* (in the press) and *Physica* (in the press). P Goldfinger, W Lasareff and M Letort, *C.R*, 200, 1593, 1935.

IN the letter above, which I had the opportunity of reading in manuscript form, Goldfinger and Lasareff calculate the heat of dissociation of CO on the basis of thermochemical and spectroscopical data and give as the most probable value 11 v.e with a possible error of not more than 0·1 v e I want to direct attention to the fact that this may be independently checked by the results of the investigation by Schmid and Gerö[1], who observed in addition to the known predissociation in the $v = 0$ level of $B^1\Sigma$, occurring at $J = 38$, another predissociation (breakdown of rotational structure) occurring at $J = 18$ of the $v = 1$ level The application of the reasoning of Herzberg[2] to this case shows that the lower limit of the asymptote of the perturbing electronic level is situated only 40 cm.$^{-1}$ below the upper limit, equivalent to 11·062 v.e, and that its real position therefore is 11 06 $\pm 0{\cdot}005$ v e. This would represent the dissociation energy of CO if the asymptote really corresponds to the dissociation in $C(^3P) + O(^3P)$ The alternative possibility that it would correspond to dissociation into $C(^1D) + O(^3P)$ and that therefore $D_{CO} = 1{\cdot}105$ v e, will be discussed in detail elsewhere.

Research and the Library

WE are in substantial agreement with the views expressed by Mr. G. E. H. Foxon in NATURE of June 8, except that he has misinterpreted the penultimate paragraph of our original article[1], as reference to it will show that it was not our intention to burke scientific debates The inclusion of these would not be overlooked by an editorial board of the calibre envisaged by us. Our point was that votes

of thanks and such superfluous matter or padding should be excised.

On the form of a paper, we feel that the introduction is often unnecessarily lengthy, except in the 'key paper' advocated by us, and ruthless editing could reduce its length in subsequent papers without sacrifice of intelligibility We agree that the incomplete paper could be checked, and our regret is that it does get printed owing to inefficient editing

We are wholly on the side of Mr Foxon on the subject of genuine research and the problem of the young worker who is merely adding professional qualification We feel that should publications adopt our recommendations genuine research would flourish, and the problem of the 'kilograms' of contributed papers be solved, by the printing of good quality material with consequent economy of time, cost and bulk.

Prediction of Earthquakes

As Mr. Broughton Edge reminds us[1], an earthquake is preceded by the building up of stress conditions The most direct way of determining stress is by the observation of strain, and the amounts of strain which have been observed prior to an earthquake have been very large.

The methods of interferometry would permit observation of such strain locally at small expense, and the surface stress throughout a large area might therefore be very readily mapped out and a continuous record made. Such observations could scarcely fail eventually to result in foreknowledge of these disastrous occurrences

Points from Foregoing Letters

FURTHER steps towards the elucidation of the chemical structure of vitamin D (calciferol) are reported by Prof I M Heilbron, K M Samant and F S Spring They suggest a three-ring formula and indicate the probable position of the double bonds and of the hydroxyl group

Prof G F Marrian and S L Cohen report that their colorimetric method for the estimation of the sex hormone, œstrin, in human pregnancy urine, is not applicable to the detection of that substance in the urine of non-pregnant women, where it exists in much smaller amounts.

Experiments with a cosmic ray detecting apparatus sending its own radio signals as it ascends into the stratosphere are reported by S. Vernoff The apparatus is likely to be useful in thinly-populated localities where the subsequent finding of self-recording apparatus sent up by unmanned balloons would present considerable difficulties

The Vegard bands in the afterglow or phosphorescence of nitrogen are, according to Prof L Vegard, due to a recombination of nitrogen atoms, derived from molecules dissociated by the bombarding rays. This view links phosphorescence phenomena with chemi-luminescence.

Dr T E Sterne suggests that if the apparently inconsistent problem in inverse probability, recently proposed by Dr. Dingle, is regarded as a problem in association, it is seen to be really self-consistent, and that the method of association reveals the nature of the fallacy involved in the use of inverse probability when the prior probabilities are unknown. Dr. Dingle, while admitting that such a combination, giving a unique result, is possible, claims that it has nothing to do with probability.

Mr. R. Maxwell Savage records that the toad, *Bombina variegata variegata*, has laid eggs in captivity at the age of three years. Males showed vigorous sexual behaviour at two years old, and signs of typical sexual reactions were seen in animals only one year old.

While agreeing with Sir Arthur Smith Woodward's warning that similar fossil animals may have developed independently in widely separated areas and are, therefore, no definite proof of Wegener's continental drift theory, Prof A E Trueman points out that identity of succession of similar forms in comparable sequence in the Upper Carboniferous rocks of western Europe and eastern America does provide strong support for the theory.

An active principle responsible for the coagulation of the blood is described by Dr Albert Fischer The active substance is apparently formed during the clotting process of the blood plasma and disappears almost instantaneously at the very moment of coagulation; it can, however, be transferred indefinitely into new plasma without decrease in its activity.

An improved type of cylindrical quartz oscillator (used in television), with a temperature coefficient of frequency a hundred times less than the usual coefficient for longitudinal vibrations of quartz, is described by L Essen

Prof E W Zehnowitzer finds that crystals of sylvine (KCl), like those of common salt, lose their brittleness after treatment with water. Such crystals recently prepared from a molten state similarly possess considerable plasticity, which may explain the frequent occurrence of bent and twisted crystals

A new, rapid and economical electrolytic method of preparing polished copper surfaces for metallurgical examination is illustrated by P. A. Jacquet. The copper is made the anode in an aqueous solution of orthophosphoric acid, and a high current density is used.

Hugh O'Neill discusses the twinning of crystals of alpha iron, which is soft and magnetic and the chief constituent of wrought iron, as evidence of previous history (cold-working and annealing) of the metal; he recalls his former suggestion that twinning in alpha iron might sometimes be associated with twinned gamma iron (non-magnetic) from which it had cooled.

The heat of sublimation of carbon, a constant used in calculating the energy of formation of carbon compounds, has a value of 167 k.cal. according to calculations by P. Goldfinger and W. Lasareff. They deduce its value from the energy of dissociation of carbon monoxide into normal atoms, as determined by thermochemical and spectroscopical methods.

Research Items

'Diminutive' Flint Implements. Diminutive flint implements—to be distinguished both by their form and their cultural associations from the microlith of upper palæolithic and early neolithic age—have been found in pliocene and pleistocene deposits in Suffolk, Lincolnshire and the Thames Valley. In describing their characteristics, Messrs. J. Reid Moir and J. P. T. Burchell point out (*Antiquaries J.*, **15**, 2) that on two previous occasions only, so far as they can ascertain, have similar implements been recorded, the first being by M. E. Pittard in 1908 in the valley of the Rebières, Dordogne, and the second in the account of the implements found with the relics of Peking man in the cave of Chou Kou Tien. These diminutive implements do not show the characteristic forms of the microlith, but are rather diminutive forms of the industries with which they have been found in association. As regards their age, the specimens now described belong to four different periods, of which the latest is much older than upper Aurignac. The earliest of the Suffolk implements are of pliocene age and pre-palæolithic type, coming from the Suffolk bone bed beneath the Red Crag. Next comes St. Acheul and early Le Moustier series from the 'Middle Glacial Gravel' (held to be of second Interglacial age) underlying the upper chalky boulder clay. Next are implements from the Upper Chalky Boulder Clay; and lastly those from the Lower Floor of late Le Moustier or early Aurignac age in Bolton and Co.'s brickfield, Ipswich. The Lincolnshire implements come from the 100 ft. and 50 ft. raised beaches below the brown boulder clay, and are middle to upper Le Moustier, and those from the Thames Valley come from the base of the 50 ft. terrace of post-Combe rock age, while others may be derived from the Boyn Hill 100 ft. terrace and possibly from the 50 ft. terrace of pre-Combe rock age. The maximum length of these flints is two inches and the minimum is ⅝ in. Their purpose seems beyond conjecture.

Equatorial Islands of the Pacific. In 1924 the Whippoorwill and Kaimiloa Expeditions of the Bernice P. Bishop Museum, Honolulu, visited the low coral islands lying within six degrees of the equator which, though uninhabited when discovered by Europeans, are supposed to have served as resting places for the Polynesian voyagers in their journeys. The results of the search for archæological remains have been recorded by Mr. Kenneth P. Emory (Bull. 123, Bernice P. Bishop Museum). On Howland Island, previously recorded excavations and mounds were examined, the most important being an irregular crescent-shaped pile of coral and shells, 18 ft. long, and a low circular enclosure. On Washington Island no artefacts of local origin have been found; but ancient stone-wall enclosures appear on the south coast. On Fanning Island an enclosure of dressed stones and a tomb near the cable station were inspected, but no excavation was permitted. The enclosure agrees in structure with Tongan and Tongarevan maraes, but, outside these, has no parallels in Polynesia. Similar stone vault burials are widely distributed in Polynesia and are especially characteristic of Tonga. In Christmas Island all the principal sites, except those on the east coast, were visited. They consist of house sites and platforms, coconut groves and ruins, and graves. There is no definite evidence of Polynesian settlement, and two village sites have yielded no artefacts, indicating temporary occupation. Petroglyphs are too indefinite to be associated with any particular area. The traces of Polynesian visitors belong to different periods and come from various directions. Jarvis Island produced no Polynesian ruins or artefacts. Three well preserved maraes were found on Malden with smaller maraes and a number of ruins. They resemble strikingly those of Raivavae and suggest an occupation of several generations. No archæological remains are reported from Starbuck Island.

The Termite Population of a Mound Colony. Termites of the species *Eutermes exitiosus*, Hill, form mound nests in parts of Australia, and an attempt has been made to ascertain the total number of individuals inhabiting such a colony. In carrying out such an estimation, there has to be taken into account the fact that all the termites living in a particular mound are never present within such a mound at any one time. Messrs. F. G. Holdaway, F. J. Gay and T. Greaves have recently published an article embodying the results of their investigations of this subject (*J. Coun. Sci. and Ind. Res.*, Australia, February, 1935). The observation that the number of individuals of the afore-mentioned species present in a given mound is greatest during the cooler months of the year led them to study the population of the mounds during such periods. Four mounds, not differing greatly in size, were dug up and their populations calculated by a method of weighing. It was estimated that 65–70 per cent of the termites in the mounds were encountered and, on this basis, the actual population was calculated to range from 747,000 to 1,806,500 individuals. The proportions of individuals in the most populous mound worked out as 1,561,400 workers, 201,000 soldiers and 44,100 nymphs. The size of the mound in question was 3 ft. 4 in. × 3 ft. 5 in. × 19 in. high.

Wing and Halter of *Tipula*. J. Zaćwilichowski (*Bull. Internat. Acad. Polonaise Sci. Lettres*, **2**, Oct.–Dec. 1934) has investigated the innervation and the sense-organs of the wings of one of the daddy long-legs, *Tipula paludosa*, employing vital staining by rongalite white for the nerve elements. He describes the distribution of the sense-hairs, sense-bristles and sense-papillæ on the wing and the three chordotonal organs which are present near the base of the wing. He regards the innervation as more primitive than that of any other dipterous wing hitherto described and as indicating that *Tipula* is very nearly related to *Panorpa*, the nerves and sense organs of the wing of which he described in a paper in the same journal in 1933. In a further paper the author describes the results of corresponding investigations by similar methods on the halter of *Tipula paludosa*, on which are sense-hairs of two types, sense-papillæ arranged in five groups, and six chordotonal organs. After discussing the distribution of the nerves in the halter and the homologies of the parts of the wing and the halter, he concludes that the halter, in contradistinction to Buddenbrock's view (1919), is to be regarded as a rudimentary wing with a remarkable

accumulation of sense organs, in consequence of which it plays a notable part in the sensory life of the fly. On the basis of these morphological investigations the halter has assumed no new function, that is, none foreign to the wing, from which it has arisen. The halter is a transformed hind-wing

Water Requirements of Indian Crop Plants. Following the methods of the American investigators, Briggs and Shantz, Prof B. N Singh and two research students, R. B Singh and K. Singh, have examined the water requirements of fifty-seven species and varieties of cereals, cotton, sugar cane, etc., when grown at the experimental station of the Institute of Agricultural Research, Benares Hindu University (*Proc Indian Acad. Sci.*, 1, No. 9, March 1935). The plants are grown in pots with carefully controlled water supply and, in the end, the total water transpired is divided by the dry weight produced, the roots being included in the yield, as was not done by the American experimenters. The amount of water available in these experiments seemed to control the yield of the varieties; the most efficient varieties, it is concluded, have a relatively short life cycle when the use of water is reduced to a minimum It is suggested that, under Indian conditions, these efficient varieties should be grown so that the number of irrigations might be controlled and thus the cost of production diminished. In their demand for water, sugar cane crops proved most greedy, and then in order came tobacco, cotton, rice, potato Other cereals, wheat, oats, barley, as also linseed, pea and mustard, had a much lower water requirement.

Gondwana Deposits of Brazil. Many new observations on the Gondwana rocks of southern Brazil are recorded in a paper by V. Oppenheim entitled "Rochas Gondwanicas e Geologia do Petroleo do Brasil Meridional" (Min. Agric., Dept. Nac. Prod. Min Bol., No 5. Rio de Janeiro, 1934). The author gives a new stratigraphic scheme along the lines of those of White and Oliveira, recording for the first time the existence of several unconformities within the Santa Catarina System. Especially notable is the one between the Lower and Upper Strada Nova, the lower member considered to be Permian while the upper one, with the pelecypod fauna described by Cowper Reed, is of Upper Triassic age. There seems also to be an unconformity between the Upper Strada Nova and the Rio do Rasto group as well as a local one between the last named group and the Botucatú sandstone. The author regards the Bonito group (lower member of the Tubarão series) as partly glacial, stating that in several localities coal seams are known underlying glacial deposits that seem to be *in situ*. These observations are of great interest because until now all the glacial deposits of Southern Brazil were indiscriminately referred to the Itararé series. It is shown that the tectonic structure of the Paraná Basin corresponds in a general sense to a geo-synclinorium with the character of a 'Graben' between Lat. S. 18° and 24°, and of a monoclinal between Lat. S. 24° and 33°. The internal structure is one of faults *en echelon* from east to west, intensively developed in successive degrees of small individual throw. The paper is illustrated with more than thirty geological profiles based on field observations and deep boring, and with a geological map to the scale of 1 : 2,750,000 comprising the Brazilian States of Rio Grande do Sul, Santa Catarina, Parana, São Paulo and parts of Minas Geraes, Goiaz and Matto Grosso as well as the neighbouring Republic of Uruguay and parts of Paraguay.

Extraction of Oil from Oil Shales and Torbanites. Great Britain is at the present time importing most of its requirements of petroleum and petroleum products Economically, this position may be sound since there are adequate resources of these commodities for some time to come. Politically, however, such dependency on foreign supplies is dangerous, as was demonstrated during the War. For this reason, attention is being constantly focused on the possibility of obtaining liquid fuel from domestic resources Hydrogenation of coal, tar or creosote is being carefully investigated, also production of liquid fuels by synthesis from carbon monoxide and hydrogen, by fermentation to alcohol vegetable products, by polymerisation of certain hydrocarbons, and extraction of oil from oil shales, sands and torbanites. Messrs. Salermo, Ltd, of 14 Waterloo Place, S.W.1, have done a considerable amount of research in connexion with the last possibility, and have recently issued a technical pamphlet on the subject. A brief account is given of the characteristics of oil shales and torbanites, their distribution and possible origin. From this it becomes apparent that oil-yielding products vary substantially in chemical and physical properties, and it is not possible to specify one plant as adequate for the extraction of oil from all types of material. The firm has, however, by dint of prolonged study of the 'primary variables', namely, rate of heating, temperature and carbonisation and rate of removal of oil vapours and gas, achieved a system of retorting which approximates closely to established principles. The Salermo retort and procéss are clearly described and illustrated in the pamphlet already referred to, and in addition carbonisation results are furnished of representative materials after treatment in this plant.

Volumetric Determination of Copper. The iodometric determination of copper depends on the addition of a soluble iodide which precipitates cuprous iodide and liberates iodine, the latter is titrated with thiosulphate. It is well known that the method has certain difficulties The reaction $2\,CuI_2 = 2\,CuI + I_2$ does not go quite to completion when the iodine is titrated, and some iodine appears to be absorbed by the precipitated cuprous iodide, which is always coloured instead of white at the end point. The addition of potassium thiocyanate with the iodide, which precipitates cuprous thiocyanate instead of iodide, does not give good results, because both iodine and thiocyanogen are liberated simultaneously and react with each other. H. W. Foote and J. E. Vance (*J. Amer. Chem. Soc.*, 57, 845; 1935) obtain better results if the titration with thiosulphate is first carried out to the point when starch is added. After adding starch, the titration is continued nearly to the end point usually observed, when about 2 gm. of ammonium thiocyanate is added for 50 c.c. of solution The blue colour immediately deepens. When the thiocyanate has been dissolved by stirring, the titration is finished. The end point is exceedingly sharp and the precipitate is white instead of slightly brownish, probably because the cuprous iodide is transformed, at least on the surface of the particles, into thiocyanate and the small amount of adsorbed

iodine is liberated. Considerable changes in hydrogen ion concentration have no measurable effect on the accuracy. The reaction takes place in stoichiometric proportions within one part in 1,600.

Shock Wave of an Explosion and Rate of Detonation. When an explosive is fired from a borehole with no filling above the charge, it not only emits flame and a considerable volume of gases, but there is also a 'shock' wave transmitted to the surrounding atmosphere This produces the concussion effect felt in the ear to a varying extent when 'shots' are fired D. B. Gawthrop has described experiments to show how the shock wave is affected by the rate of detonation (*J. Franklin Inst*, April) It advances in the air ahead of any forward movement of the gases from the explosive If in unconfined space it expands spherically in all directions, its velocity diminishing, and it ultimately degenerates into a normal sound wave. The paper describes a research made to determine the velocities of the shock waves sent out by the explosives at widely differing rates of detonation. Definite indications had been previously obtained that the rate of detonation is a factor which affects the safety of the explosives when fired in the presence of firedamp. It was found that with a certain charge the average speed of the shock wave at a distance of 15 cm. from the mouth of the borehole was 1,135 metres per second, but at 135 cm. it was only 350 m p.s Quadrupling the weight of the charges, the corresponding speeds were found to have increased to 1,670 and 450 m p s respectively The experiments made showed that the rate of detonation had no effect on the velocity of the shock wave sent out As the weight of the charge increases there is a decrease in safety in firedamp, and we now know that there is also an increase in the velocity of the shock wave

Preservative Treatment of Wooden Sleepers. As a result of the work and researches of Sir Ralph Pearson and others, carried on by successors, Forest Bulletin No. 85 (Delhi: Manager of Publications, 1934) has recently appeared entitled "A Record of the Results obtained with Experimental Treated Sleepers laid in Indian Railways between 1911 and 1916", by S Kamesam of the Wood Preservation Section of the Research Institute at Dehra Dun. Between 1911 and 1916 some thousands of wood sleepers of several species of Indian timbers were treated with different preservatives at Dehra Dun and then laid down by the railway authorities in the various railway systems of India. As a result of these experiments, the confidence of Indian railway engineers in wood preservation has been steadily and definitely strengthened. Coal-tar creosote, as in other parts of the world, has given excellent results The Indian railways are thoroughly satisfied with a creosote-crude oil treatment for their sleepers, and it has become the standard treatment during the last decade. In reviewing, however, the results obtained in the present series of test sleepers, and considering that creosote costs in India more than twice as much as it does in Europe, Mr. Kamesam states that there are great potentialities for cheaper preservatives, such as arsenic, on the basis of wood preservative "efficiency for a unit of cost". Tabular statements record the number of the sleepers laid in different parts of India (except the south), and give data as to the method of treatment and their subsequent life-history.

Pulsation in Electric Mains. We have now throughout Britain hundreds of very powerful dynamos (alternating current generators) all working practically in step with one another although the frequency is 50 per second. In the early days of electricity supply, John Hopkinson found mathematically that two alternators could run in parallel with one another, a slight falling out of step being accompanied by powerful forces tending to make them fall into step again. Practical experience has shown that instability may arise from the nature of the load, and if we have many machines working in parallel and interconnected by long mains, serious pulsations of the current may be set up which may open the circuit breakers and interrupt the supply. In a paper by W D Horsley read to the Institution of Electrical Engineers on March 28 an investigation is made of different conditions of operation which may give rise to these pulsations The value of automatic voltage regulation is discussed and it is shown that it is of considerable value in increasing the load limit and stability of an alternator. When it is used, the load of the system is only limited by the values of the constants of the transmitting line In America the corresponding problem is more difficult because the power stations have to be interconnected by very long transmission lines In addition, they have large hydro-electric plants linked together with steam generating plants. In designing the British grid full advantage was taken of experience gained abroad Luckily the lightning problem is not a serious one in Great Britain The most severe types of disturbance we suffer from are due to faults in the network, and so the quicker the speed of operation of protecting apparatus and switch gear the better

A Test Recorder for Electric Lamps. The manufacturer of incandescent lamps is obliged, in order to control the quality of his product, to make a large number of life tests of individual samples In order to get the maximum benefit from these tests, they have to be made on a large scale under expert supervision The large consumption of electric energy during the 1,200-hour test is quite a serious addition to the cost of manufacture of the lamp It has now been found that by increasing the voltage applied over the rated voltage of the lamps, the time necessary for the complete test can be considerably shortened For example, the life-history of a batch of lamps which would normally average 1,200 hours burning could be found in twelve hours. In the *G E C. Journal* of May, G. Chelioti gives a full description of the test recorder used by the Osram-G E C. works This works has had considerable experience of the shortened method of testing, but before the introduction of the recorder it was found that the necessary continuous supervision for the 12-hour test put a great strain on the supervisors, as unless the time at which each of a long row of lamps burns out was recorded with fair accuracy, large errors arose. Human frailty is a large factor as the work is extremely monotonous, and it is practically impossible to check the records Hence an electrical recorder which would relieve the worker of this dreary task and give a permanent record of unimpeachable authority was welcomed. In the full-life test at the rated voltage, it is customary to make checks every 12 hours; in the abbreviated test they are made every six minutes.

The David Dunlap Observatory, Toronto

ALTHOUGH most of the astronomers of Canada are graduates of the University of Toronto, hitherto the University has possessed no observatory This want has been recently supplied by the munificence of Mrs D A Dunlap, who has presented the University with a 74-inch reflecting telescope, as well as a handsome administrative building The inauguration ceremony took place on May 31, the chair being taken by the president of the University, Canon Cody, in the presence of the Lieutenant-Governor, Dr Bruce, Sir Robert Falconer (a former president of the University), Mr. Mackenzie King (a former Prime Minister of the Dominion), professors of the University, and astronomers from Great Britain, Canada and the United States, and a thousand interested visitors

After a dedicatory prayer by the Rev. E W. Wallace, Chancellor of Victoria College, the chairman read letters of congratulation from the president of the International Astronomical Union, the president of the Royal Astronomical Society of Canada, Sir James Jeans and Sir Arthur Eddington He then called on the architect, who handed a golden key to Mrs. Dunlap. She opened the door with the words, "In loving memory of my husband, David Alexander Dunlap, I now present this astronomical observatory to the University of Toronto, believing this memorial will express his deep interest in astronomy, and I hope through its equipment great advances will be made in the science", and handed the key to Dr. B M Macdonald, chairman of the Board of Governors.

After a warm expression of thanks by Dr Macdonald, a sincere tribute to Mr Dunlap was paid hy him and by the Lieutenant-Governor The president then called on Prof. Chant, the director of the Observatory, and noted that the inauguration had been fixed on Prof. Chant's seventieth birthday Prof Chant referred to Mr. Dunlap's great interest in astronomy, and said that in 1926 he ventured to lay the project of an observatory in Mr. Dunlap's memory before her The foundation stone was laid in 1932 by Mr Moffatt Dunlap "To Mrs. Dunlap all the credit is due; were it not for her there would be no observatory here"

Mr Cecil Young, manager of the firm of Sir Howard Grubb, Parsons and Co., then gave an account of the large telescope and dome which were described and illustrated in an article in NATURE of October 14, 1933 Sir Frank Dyson gave the good wishes of the Royal Astronomical Society, and congratulated Prof Chant on the great interest in astronomy in Canada, which was in large measure due to him. Short addresses were given by Prof. H. D Curtis, director of the Observatory of the University of Michigan, Prof. V. Slipher, director of the Lowell Observatory at Flagstaff, Prof H. Shapley, director of the Harvard College Observatory, and Dr W. E. Harper, director in charge of the Dominion Observatory at Victoria

The Observatory is situated in 160 acres of ground on Richmond Hill, some twelve miles north of Toronto, from which a beautiful view extends in all directions It is sufficiently distant from Toronto to avoid smoke and glare, and yet near enough to the University. The number of good observing nights is estimated at about 120 in the year. The administration building is a handsome structure of stone, surmounted by three domes for smaller telescopes. It contains office and computing rooms, a library and well-equipped workshops The large telescope is in a steel dome with the necessary insulating material to diminish changes of temperature, and was constructed by Messrs Sir Howard Grubb, Parsons and Co The general appearance of the telescope in relationship to the dome is very satisfactory The clockwork and the electrical movements of the telescope and dome fulfil all requirements. The mirror of 74 inches is of pyrex, made by the Corning Company of New York. The grinding and figuring of the mirror were carried out at Newcastle, under Mr Cyril Young's direction, by Mr Armstrong, the very competent artist of the firm. The spectroscope was constructed by Messrs. Adam Hilger, Ltd., and is admirably adapted to determine velocities in the line of sight for which the instrument will be generally used. Telescope and spectroscope were thoroughly tested by Mr R. K Young. In Mr Young, Mr. Hogg and Mr. Millman, Prof. Chant has an able, experienced and enthusiastic staff. We may look with confidence for an excellent output of work from the David Dunlap Observatory.

F. W. DYSON.

Humoral Transmission of Nervous Impulses*

IN 1921 it was proved for the first time that the modifications of the heart's function, caused by stimulation of its nerves, are due to substances liberated by the stimulation, called transmitters: acetylcholine and an adrenaline-like body respectively, which in their turn bring about the effects of stimulation This 'humoral transmission of nervous impulses' occurs, not only in the heart, but also with stimulation of all the other vegetative nerves. Whether it also happens within the somatic nervous system is not yet settled.

The nerves releasing transmitters on stimulation do not influence the *function* of their effective organs otherwise than by this release. But we must attribute to them an influence—independent of the release of the transmitters—on the *sensitivity* of their effector organs to peripheral, directly applied stimuli.

The discovery of the humoral transmission of nervous impulses discloses the hitherto obscure mechanism of the effect of nervous stimulation in general, and also particularly of peripheral inhibition.

As to the point of attack of nervous stimulation, that is, the localisation of the release of the transmitters, there are two possibilities: either the nerve-ending or the effective organ. There are many arguments against the latter possibility, but the former is supported by the following: (1) after nerve

* Substance of the Ferrier Lecture delivered by Prof. Otto Loewi, professor of pharmacology in the University of Graz, before the Royal Society on June 20

degeneration, the transmitter disappears, even in cases in which the effective organ is not degenerated at all, (2) on stimulation of the preganglionic cervical sympathetic the transmitter is liberated, not within the ganglion cell, but at the synapse—in other words, from the nerve-ending Regarding the *mechanism* of the release we have to consider also two possibilities: either the transmitter is newly formed by the nervo-stimulation, or it is made diffusible, being split off from a combination already present in the nerve-ending. The decision between these alternatives cannot yet be made

The lapse of time between the nerve-stimulation and the response of the reacting organ is extremely short, even in organs like the heart, where the transmitter has to pass a certain distance in order to reach the effector cells The transmitters disappear somewhat quickly, the time of disappearance being dependent on the type of action which they have to produce

The point of attack of the transmitters is not a part of the neurone, but the functioning, effective organ itself The fact that the transmitters, when artificially injected, mainly act at points in relation to which they are normally liberated, can be given, as yet, only a teleological interpretation Since the transmitters can diffuse into the blood from the point of their release, they can, in principle, also affect remote organs, though under physiological conditions this may never happen Obviously such a distant action is unnecessary, as such needs are fulfilled by the hormones

Finally, the question is considered whether the difference between the action of the hormones and that of the transmitters concerns only the sphere or also the character of their action The hormones of two of the ductless glands, both being neurotropic and differing from all other ductless glands by properties common to them only—the adrenal medulla and the posterior lobe of the hypophysis—initiate or modify, according to need, the specific *function* of the organs, as the nerves or the transmitters do

All the other ductless glands are not neurotropic, they depend largely on the anterior lobe of the hypophysis regarding their development and state, their secretion is going on continuously and automatically, though partly controlled by the nervous system. Their action is concerned less with the *specific functions* of organs than with *general conditions*—state and metabolism In other words, there are differences not only regarding the sphere but also regarding the character of the action of the nerves and the transmitters, on one hand, and that of the hormones on the other.

Cosmic Ray Results of the American Stratosphere Balloon *Explorer I*

BRIEF accounts have been given in NATURE[1] of the flight of the American stratosphere balloon *Explorer I* and the subsequent mishap by which it was at first feared that most of the valuable photographic records had been destroyed. Subsequent expert development of the films shows that, whilst the whole of the objectives have not been secured, those records that have been saved have yielded interesting and confirmatory results to collateral researches.

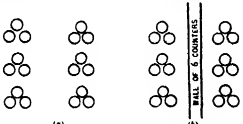

FIG 1

Swann and Locher have contributed an article on "The Variation of Cosmic Ray Intensity with Direction in the Stratosphere", and Millikan a short article on the results of the flight in "Stratosphere Series, No. 1" of the U.S. National Geographic Society. In the former of these researches, as many as 168 Geiger-Müller counters were employed These were disposed as in Figs 1a and 1b In each case three counters close together form a unit, and corresponding ones of the nine counters on either the right or duplicate left side of Fig 1a must be influenced for a count. There were four such banks for the directions 0°, 30°, 60° and 90° to the vertical. In Fig. 1a, the counters are in the 0° position. The whole system was now duplicated as in Fig. 1b, with the addition of a wall or partition of six *neutralising* counters dividing each bank. Apart from the influence of this wall on the time resolution, the arrangement of counters in Fig 1b would have the greater directive tendency Two systems of recording were employed, one in which the total number of counts in a given time was integrated, and the other in which each individual count was recorded and timed. The curve of the spatial distribution of the rays at an altitude of 40,000 ft for the two arrangements of the counters is shown in Fig 2, in which the curve *a* corresponds to the arrangement of Fig 1a and the curve *b* that in Fig. 1b. The number of counts varies from about 5 per minute for rays from the horizontal direction to about 20 per minute from the vertical at this height, whilst the more recent results from a flight by J. Piccard in America give similar curves up to 53,000 ft The dotted curve *a*, which includes

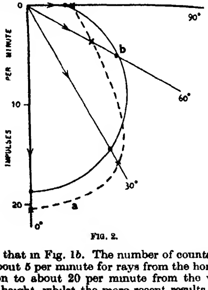

FIG. 2.

showers as well as individual rays, seems to show that the showers, on the whole, tend to come from the zenith.

When the average curve is integrated over a hemisphere and compared with a similar integration at sea-level, the ratio of the counter actions at the two heights is 64 Millikan's result with a thin-walled ionisation chamber at 40,000 ft. is $J = 250$ ions per c c. per sec, so that if counter action is to be compared directly with volume ionisation by cosmic rays, the value of J at sea-level would be $250/64 = 3 \cdot 9$ ions per c c per sec. As against this value for J three direct determinations are quoted, namely, Millikan 2·4, Compton 1 9, Hoffmann 1 0 Comparison of the mean of these three figures with 3·9 indicates that counter action does not increase at the same rate with altitude as volume ionisation in a given locality This is generally taken to mean that there is an increasing admixture of particles in higher altitudes that will not penetrate the counters but that will penetrate the walls of the ionisation chamber

The Neher recording shielded electroscopes were destroyed in the crash, but an unshielded one gave a record up to 60,000 ft The result for J agrees with that of the Fordney Settle flight of November 1933

Surface Chemistry and its Industrial Applications

FEW industries are not dependent, at some stage in their processes, on reactions between matter in different states of aggregation, and consequently few industrial chemists can afford to ignore the recent developments in our knowledge of the physical and chemical changes that occur at surfaces. It is not surprising, therefore, that there was a record gathering for the discussion on the theoretical aspects and industrial applications of surface chemistry arranged by Section B for the Melbourne Centenary meeting of the Australian and New Zealand Association for the Advancement of Science. Prof. J C. Earl was sectional president.

Dr. T. Iredale, opening the discussion, reviewed recent advances in the theory of surface chemistry, and other theoretical papers were presented by Dr. J E. Mills on "The Recombination of Atoms and Free Radicles at Surfaces" and Dr. N. S. Bayliss on "A Critical Review of the Parachor". The contention that the parachor is of little value in determining the constitution of organic compounds was supported by Dr. R. A. Robinson. Mr. R. S. Burdon discussed the influence of carbon dioxide and hydrogen on the surface tension of mercury. Measurements of the amount of gas liberated by decreasing the surface area of a mercury surface prove that it adsorbs a unimolecular film that is tenaciously held, even in high vacuum. Prof E. J Hartung and the staff of the Chemistry Department of the University of Melbourne prepared a remarkably clear film of the Brownian movement in colloidal solutions. This film demonstrated the disintegration of benzopurpurin, the coagulation of copper ferrocyanide by sunlight, and the electrophoretic movement of the particles in either direction as the polarity of an applied electrical field was reversed. With a screen magnification of 40,000, the translational, vibrational and rotational movements of colloidal particles were clearly seen.

Papers dealing with industrial applications of surface chemistry were delivered by Mr C. Blazey on "The Effect of Service Conditions on Metal Surfaces", Mr. A. R. Hogg on "The Contact Process for Sulphuric Acid" and Mr. J. S. Wilson on "A Résumé of Current Theories of the Process of Dyeing Textile Fibres". No single theory of dyeing has yet been able to explain how the various types of dye are taken up silk, cotton and wool fibres.

At a joint discussion with Section H on "Corrosion", papers were delivered by Prof. J. N. Greenwood on "The Combined Influence of Stress and Corrosion on Metals", Prof A. Burn on "Cavitation in Turbines and Centrifugal Pumps", Dr. G A. Elliott on "The Passivity of Metals in relation to Corrosion", Mr. P. F. Thompson on "Modern Theories of the Corrosion of Metals", Mr. C. J. Griffiths on "Electrolytic Corrosion" and Mr. V. Wardell on "Inhibitors of the Acid Corrosion of Metals" Mr Wardell, discussing the cleaning of iron for galvanising, enumerated a great variety of substances that, though not preventing the removal of scale by acids, greatly reduce or even prevent the dissolution of iron Glue is commonly used for this purpose. Generally known as inhibitors, these substances are used also for cleaning boilers and water mains The addition to hydrochloric acid of a little arsenic chloride, while preventing dissolution of the steel base of galvanised iron, does not seriously retard the solution of the zinc coating.

Most of Australia's secondary industries, being still in the early stages of development, are forced to concentrate upon the solution of purely local problems. The base metal mining industry, however, grateful for benefits from the research work of other countries has, with the co-operation of the University of Melbourne, established a research laboratory for the investigation of the fundamental physico-chemical principles underlying the flotation process. Mr. H. Hey, opening a discussion on the chemistry of flotation, outlined its development from the laboratory stage, through the original large-scale operations at Broken Hill, to its present world-wide application to a great variety of ores Mr. A B Cox and Dr. Ian W. Wark then described the work of the University laboratory. The flotation of a mineral depends upon its surface being modified so that it will adhere to an air bubble. Contact angle gives a quantitative measure of the condition of the surface. The influence of the adsorption of various organic compounds known as *collectors* on the magnitude of the angle of contact, and the influence of several inorganic compounds on their adsorption, have been determined. It is concluded that a unimolecular orientated adsorption of the collector is responsible for the attachment between mineral and air bubble. There is not yet agreement as to the mechanism of adsorption.

At a luncheon given by the Australian Chemical Institute, Dr. T. Callan conveyed greetings to the chemists of Australia from the Institute of Chemistry of Great Britain and Ireland and from the Society of Chemical Industry.

University and Educational Intelligence

CAMBRIDGE.—The following appointments have been made E. Farmer, of Trinity College, reader in industrial psychology, E. G. Chalmers, of Clare College, assistant director of research in industrial psychology, P. Graffa, of King's College, assistant director of research in economics, Dr. J. K. Roberts, of Trinity College, assistant director of research in colloid science, Dr W A Wooster, of Peterhouse, lecturer in mineralogy and petrology, E T C. Spooner, of Clare College, lecturer in pathology, G. C. Grindley, lecturer in experimental psychology, N Dean, of Trinity Hall, lecturer in estate management, C. Culpin, of St John's College, demonstrator in agricultural engineering, Dr. J D. Cockcroft, of St John's College, lecturer in physics, P I. Dee, of Sidney Sussex College, lecturer in physics, Miss A C. Davies, of Newnham College, lecturer in physics, Dr. M. L. E. Oliphant, of St John's College, assistant director of research in physics, Dr. W B. Lewis, of Gonville and Caius College, demonstrator in physics.

Prof E V Appleton, Wheatstone professor of physics, King's College, London, has been appointed Scott Lecturer for the year 1936–37

H McCombie, of King's College, has been approved for the degree of Sc D

Dr C S Myers has been elected to an honorary fellowship at Gonville and Caius College

EDINBURGH.—The first Sharpey-Schafer Memorial Lecture, given on June 21 by Sir Charles Scott Sherrington, was a notable tribute paid to the late distinguished physiologist by his fellow-worker and friend. Sir Charles referred more particularly to Sir Edward Sharpey-Schafer's work in endocrinology and in neurology, and dwelt on the great interest and importance of the observations made by Schafer in 1877 on the nerve-elements in the jelly-fish *Aurelia*, and in his later work on localisation in the cerebral cortex and on the structure of the spinal cord

Dr. C. G. Anderson has been appointed Lewis Cameron teaching fellow in the Department of Bacteriology. This is the first appointment under the scheme recently approved by the Court of Session for the administration of the Lewis Cameron Fund.

LEEDS.—Prof Stroud has given £1,000 towards the Union building, and £100 for the Physics Museum.

Prof. J H Priestley has been appointed Pro-Vice-Chancellor of the University for a period of two years from July 1.

Mr B. H. Wilsdon, director of the British Wool Research Association, has been appointed director of research students at Torridon under the scheme of co-operation between the University and the Association.

LONDON.—Dr. H. L. EASON, superintendent and senior ophthalmic surgeon of Guy's Hospital, has been elected Vice-Chancellor for the year 1935–36, and the Rev. H. B. Workman has been appointed Deputy Vice-Chancellor for the same period.

The Right Hon. Lord Hanworth, the Master of the Rolls, has been appointed Creighton Lecturer for the year 1935–36. The lecture, entitled "The Preservation of our Archives, National and Local", will be delivered at the London School of Economics during the Michaelmas term.

OXFORD.—The Johnson Memorial Prize for 1935 has been awarded to Dr. T G Cowling, Brasenose College, at present lecturer in mathematics at the University College of Swansea The prize consists of a gold medal of the value of ten guineas, together with a sum of money. It is awarded once every four years for an essay on some astronomical or meteorological subject. It is understood that Dr. Cowling's essay was entitled "Convection in Stars"

ST. ANDREWS.—At a meeting of the University Court held on Saturday, June 22, the following appointments to vacant chairs in University College, Dundee, were made —*Mathematics* Dr E. T. Copson, Royal Naval College, Greenwich, *Physiology* Dr. Robert C. Garry, Rowett Research Institute, Bucksburn, Aberdeen.

PROF. J GRAHAM KERR, F R S, regius professor of zoology in the University of Glasgow, has been elected M P for the Scottish Universities. The by-election was caused by the appointment of Lord Tweedsmuir (formerly Mr. John Buchan) as Governor-General of Canada The voting was Prof. J Graham Kerr (Nat Govt), 20,507, Mrs. N Mitchison (Lab), 4,293 As remarked in a note referring to Prof Graham Kerr's candidature in NATURE of June 1, p 919, his election involves giving up the life tenure of his professorial chair

Science News a Century Ago

Middlesex Hospital Medical School

Sir Charles Bell (1774–1842), the surgeon, writing to his brother George Joseph Bell (1770–1843), the lawyer, on June 29, 1835, said .

"My dear Brother,

"We have founded a school in the garden of the Middlesex Hospital. The building will be a complete little thing—theatre, museum, clinical class-room and dissecting room. But you must admire my spirit to commence such an undertaking at this day I promise to the extent of sixty lectures To the work I have no objection, but there will be a great outlay also, although from the way in which it is taken by the governors, I believe subscriptions will cover all expenses. The building will cost £2,400"

Writing again on July 22, he said: "Would you believe that our school is already roofed? It seems like magic. We pay for that, however But for dispatch we might have had it built for much less".

Locomotives on the Liverpool and Manchester Railway

Quoting from a paper read by Mr. David Stevenson to the Scottish Society of Arts, the *Mechanics' Magazine* of July 4, 1835, said: "The Liverpool and Manchester Railway locomotive-carriages are of three kinds, and are called train, luggage and bank engines. The train-engines average about 30 horses' power; they weigh about 8 tons, and cost about £900 The luggage-engines are in general, 35 horses' power, and weigh about 9 tons; they cost about £1,000 There are only two bank-engines, the *Goliath* and *Samson*, which are used for assisting the trains up the inclined planes at Whiston and Sutton, they are about 50 horses' power, weigh about 12 tons and cost

about £1,100. The Company has had altogether 32 locomotive-carriages made. . . The *Vulcan*, a train engine, ran no less than 47,000 miles before it required to be repaired; and the *Firefly* ran 50,000 miles. The greatest speed which the engines have been able to obtain on a level is 60 miles per hour, without a load "

Death of Sir Edward Banks, 1770–1835

On July 5, 1835, Sir Edward Banks died at Tilgate Lodge, Sussex, and a few days later was buried at Chipstead, Surrey, where both his tomb and monument are to be seen Born near Richmond, Yorkshire, on January 4, 1770, in a humble station of life, Banks raised himself to the highest position among civil engineering contractors, and "during 40 years was engaged on the erection of some of the most useful, extensive and splendid works of his time". His earliest experience was gained in canal construction in the north of England, partly under John Rennie and William Jessop. Probably through the latter he became connected with the Surrey Iron Railway from Wandsworth to Merstham, and was thus brought into contact with the land-owning family of Jolliffe at Merstham In 1807 he entered into partnership with the Rev William John Jolliffe (1774–1835), who abandoned the Church for engineering, and the partners were soon engaged on a succession of important works, which included the Waterloo, Southwark, London and Staines Bridges over the River Thames They also carried out contracts in connexion with the ports of Howth and Goole, Deptford and Sheerness Dockyards, and with the improvement of the Rivers Nene, Witham and Ouse The bridge over the Serpentine, Hyde Park, was built by them in 1824 On June 12, 1822, Banks was knighted for "the extraordinary exertions, industry, skill and perseverance he had displayed in the execution of the Waterloo and Southwark Bridges", this being the first instance of this honour being bestowed on a professional engineer.

Alphonse De Candolle's Treatise on Botany

Among the natural history works of lasting interest published in 1835 was the "Introduction à l'etude de la Botanique ou Traité Elementaire de cette Science" of Alphonse De Candolle, professor at the Academy of Geneva A review of this work appeared in the July issue of the *Records of General Science*. "This work," said the review, "may therefore be considered the most complete treatise which has appeared on the subject, and it is written with great precision and clearness. It exhibits a great extent of botanical knowledge, and is accommodated to the present state of the science,' as the author states the opinions brought forward in the most recent European works of botany, and candidly adopts those which appear to him of most weight. . . . The most curious and novel part of the work is that which relates to botanical geography. The most imperfect part of the work is that which treats of the superior phenomena, which escape our physical explications, and which depend on unknown powers, which we are in the habit of designating by the obscure name of vital powers, because they are connected with the preservation and permanence of the species . . . The explanation of all these phenomena, and many others, will, however attract the attention of botanists, and sooner or later, we may expect them to be elucidated."

Societies and Academies

DUBLIN

Royal Dublin Society, May 28. W. J. LOOBY and J. DOYLE Fertilisation and pro-embryo formation in *Sequoia*. Fertilisation takes place in Irish material of *Sequoia gigantea* in August of the first year, being rapidly followed by pro-embryo and early embryo development. The embryo is not completed until the second year, the winter being passed in the embryo-with suspensor stages. The pro-embryo only occupies the lower part of the archegonium, with wall formation at the eight-nuclei stage, the complete pro-embryo showing a 2 – 6 – 6 or a 3 – 5 – 5 arrangement *Sequoia sempervirens*, though forming a wall at the first division of the fusion nucleus as already recorded leaves unused protoplasm at the top of the archegonium, the pro-embryo frequently occupying only one half of it. E J SHEEHY Note on the effect of storage on the colour and on the free fatty acid content of a commercial sample of veterinary cod liver oil Slight hydrolytic and very considerable oxidative changes occurred in veterinary cod liver oil stored under different conditions Colour changes associated with increased free fatty acid content, and induced by contact with the material of the container, occurred. REPORT OF THE IRISH RADIUM COMMITTEE FOR THE YEAR 1934. This include reports submitted by medical users of radon supplie by the Committee, and records the treatment o 441 malignant and 149 non-malignant cases This is a considerable increase over the total number (466 recorded in the 1933 report. A tendency towards th use of smaller doses has, however, reduced the tota quantity of radon issued from 12,996 mC in 1933 t 11,744 mC in 1934.

EDINBURGH

Royal Society, June 3. T NICOL. Studies on th female reproductive system in the guinea pig intravitam staining; fat production, influence c hormones Special cells showing maximum amoun of trypan blue occur in the endometrium only i large numbers at certain stages of the sexual cycle and are practically absent in sexually immatur animals. This condition, absent in ovariectomise animals, was produced by œstrin injections, but by administration of corpus luteum hormone or an terior pituitary The fat deposit also appeared cycli and was produced artificially in ovariectomise animals by injection of corpus luteum extract, afte sensitisation with œstrin. In the pregnant anima around the embryo, cells, proved endometrial b development, absorb the dye and form embryotroph The results as a whole indicate that the function cells absorbing the dye is histiotrophic. G. BOND The endodermis in light-grown and etiolated shoo of the Leguminosæ: a contribution to the caus study of differentiation in the plant. Priestley observations on the promoting effect of etiolati upon differentiation of primary endodermis in t shoots of various members of the Leguminosæ ha been confirmed and extended in the present wor Light appears to be the particular environment factor responsible for the non-development of th endodermis in these shoots under normal growth conditions In other leguminous plants, the effec of etiolation was less marked. The developmen

under normal conditions of the basal endodermis in *Vicia Faba*, etc., does not appear to be entirely due to the differentiation of the first internodes in darkness occasioned by the soil or by the presence of the cotyledons. The initial development of these internodes in the darkness of the ovary may also be responsible. R. A. ROBB and T. R. TANNAHILL: Lunar atmospheric inequality at Glasgow. An analysis of the Glasgow Observatory hourly barograph records, 1868–1912, rearranged according to lunar time, shows that there are significant diurnal and semi-diurnal variations of pressure, for the 4,290 days considered, during which the daily range of pressure did not exceed 0·1 in of mercury, the variations can be represented by 0 0640 sin (θ – 267°) millibar, and 0·0156 sin (2θ – 285°) millibar The data were also subdivided in various ways as in Prof Chapman's investigation of a similar nature All subdivisions show characteristics similar to those for the total data as given above

tissues physical development Detection of gold in animal tissues by physical development in a solution of gum arabic silver nitrate hydroquinone and citric acid Miss M A KENNARD Clinical and histological observations on a case of primary cortical degeneration of the cerebellum A case of progressive ataxia showed complete degeneration of the Purkinje cells of the cerebellum A DE BUCK and N H SWELLENGREBEL Further studies on and discussion of the results of cross mating the races (varieties) of *Anopheles maculipennis* Crossing experiments with *Anopheles* from Sweden and Holland showed that the varieties were identical in the two countries H J MACGILLAVRY Remarks on Rudists

SYDNEY

Royal Society of New South Wales, May 1 R J NOBLE Some aspects of problems associated with the preservation of health in plants (presidential address) Reference was made to early records of the occurrence of plant diseases in New South Wales and to the urgent need for more general adoption of established measures of control in order that there might be greater stability in agricultural production The conditions of health and disease are not always readily differentiated Submerged infections delayed development of symptoms and virus masking are phenomena of academic interest and practical importance Variability and plasticity of host and pathogen and the significance of factors in the environmental complex were discussed Synergic and antibiotic phenomena are being more widely recognised in local problems Climatological factors were reviewed in relation to plant quarantine and spray forecasting services Virus diseases were discussed in relation to plant responses and the question was raised as to whether any groups of symptoms are comparable physiologically with those resulting from other causes

ROME

Royal National Academy of the Lincei, March 17 T BOGGIO Integration of Helmholtz's hydrodynamic equations A direct integration of these equations to obtain Cauchy's integrals is given F TRICOMI The inversion of Laplace's transformation B MANIÀ Conditioned problems of the calculus of variations R L GOMES The deduction of Lorentz's formulæ D GRAFFI The effect of a variation in mass on a planetary orbit R L GOMES Considerations on the fundamental equation of Louis de Broglie's "New Conception of Light" L SOBRERO Functions analogous to potential in mathematical physics G R LEVI and D GHIRON Action of arsenic acid and arsenates on hydrogen peroxide In small proportions arsenic acid has a stabilising action on hydrogen peroxide but at higher concentrations the ion AsO_4 exhibits a specific decomposing effect L MUSAJO Investigations on xanthurenic acid (2) The results of experiments in which various animals were fed with fibrin show that, with the albino rat or rabbit, xanthurenic acid, quinurenic acid and quinurenin are eliminated in the urine and with the dog quinurenic acid and quinurenin without xanthurenic acid L MUSAJO and F M CHIANCONE Investigations on xanthurenic acid (3) genesis of the acid In the rat, xanthurenic acid is formed from tryptophane, probably with intermediate formation of quinurenin
